(1) In the figure below we show the torus M as a submanifold of $\mathbb{R}^3$ and we consider the "height function" $f\colon M \to \mathbb{R}$ given by $f(x, y, z) = z$. This function has precisely four critical points which are indicated in the figure on the left. On the right we show a regular value s and its preimage $f^{-1}(s)$ and we show a critical value t and its preimage $f^{-1}(t)$ which in this case is *not* a submanifold of M.

[280] We refer to page 670 for the definition of a short exact sequence.

(2) In the figure below we consider again a smooth manifold $M \subset \mathbb{R}^3$ together with the "height function". But this time M has boundary and $f^{-1}(s)$ is a proper submanifold of M with non-empty boundary.

(3) We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}^{n+1} & \to & \mathbb{R} \\ (x_1, \ldots, x_{n+1}) & \mapsto & x_1^2 + \cdots + x_{n+1}^2. \end{array}$$

Since $\mathrm{D}f_{(x_1,\ldots,x_{n+1})} = (2x_1 \ \ldots \ 2x_{n+1})$ we see that each point in $\mathbb{R}^{n+1} \setminus \{0\}$ is a regular point and each non-zero $r \in \mathbb{R}$ is a regular value of f. In particular it follows from the Regular Value Theorem 26.4 that $S^n = f^{-1}(1)$ is an n-dimensional submanifold of $\mathbb{R}^{n+1}$. This proof is significantly more pleasant than the original proof on page 553. Furthermore we see that for each $P \in S^n$ we have

$$\widetilde{\mathrm{T}}_P S^n \ = \ \ker(\mathrm{D}f_P\colon \mathbb{R}^{n+1} \to \mathbb{R}) \underset{\uparrow}{=} \{v \in \mathbb{R}^{n+1} \mid \langle v, P\rangle = 0\}.$$

by the above calculation of $\mathrm{D}f_P$

We have thus found a new proof of Lemma 23.1 (3). In Exercise 26.13 we determine for which $\in \mathbb{N}$ the orientation defined by the Regular Value Theorem 26.4 (3b) on S^n agrees with the standard orientation that we introduced on page 681.

(4) Let $g \in \mathbb{N}_0$. By [**Hirs1976**, p. 28] there exists a polynomial function $f\colon \mathbb{R}^3 \to \mathbb{R}$ such that 0 is a regular value and such that $f^{-1}(0)$ is diffeomorphic to the surface of genus g. For example, if we take

$$f(x,y,z) \ = \ (4x^2(1-x^2) - y^2)^2 + z^2 - \tfrac{1}{4},$$

then [**Hirs1976**, p. 28] states that $f^{-1}(0)$ is diffeomorphic to the surface of genus 2. This shows in particular that the surfaces of genus $g \in \mathbb{N}_0$ are diffeomorphic to submanifolds of $\mathbb{R}^3$. This was always "clear", but it is somewhat challenging to prove rigorously.

Proof of the Regular Value Theorem 26.4. Let M be an m-dimensional smooth manifold, let N be an n-dimensional smooth manifold, let $f\colon M \to N$ be a smooth map and let $s \in N \setminus \partial N$ be a regular value of f. We write $X = f^{-1}(s)$.

(1) Let $P \in X$. Since s is a regular value we know that P is a regular point.

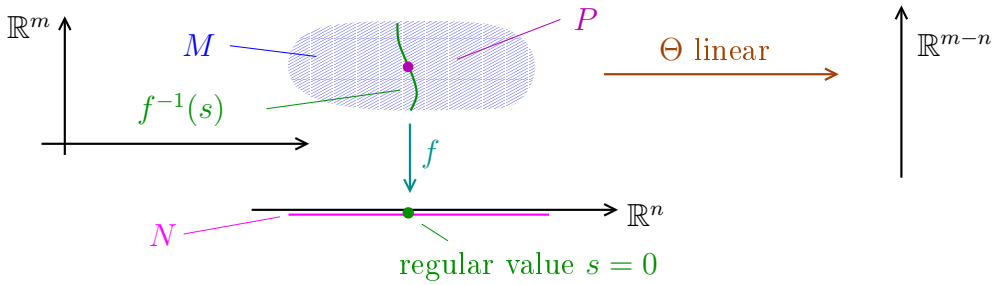
Claim.

(α) If $P \in M \setminus \partial M$, then there exists an $(m-n)$-dimensional submanifold chart of type (α) around P.

(β) If $P \in \partial M$, then there exists an $(m-n)$-dimensional submanifold chart of type (β) around P.

Proof. First we consider the case that $P \in M \setminus \partial M$. This means that we can pick a chart of type (i) for $P \in M$. Since by hypothesis $s \in N \setminus \partial N$ we can also pick a chart of type (i) for $s \in N$. In fact this shows that we might as well assume that M is an open subset of $\mathbb{R}^m$ and that N is an open subset of $\mathbb{R}^n$. Furthermore after a translation we can assume that $s = 0$.

It follows from the fact that P is a regular point in $M \setminus \partial M$, together with the Tangent Space-Isomorphism Proposition 23.16, that the map $\mathrm{D}f_P \colon \mathbb{R}^m = \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_s N = \mathbb{R}^n$ is an epimorphism. This implies that we can pick a linear map $\Theta \colon \mathbb{R}^m = \widetilde{\mathrm{T}}_P M \to \mathbb{R}^{m-n}$ such that the map



$$\mathrm{D}f_P \times \Theta \colon \underbrace{\widetilde{\mathrm{T}}_P M}_{=\mathbb{R}^m} \;\to\; \underbrace{\widetilde{\mathrm{T}}_s N}_{=\mathbb{R}^n} \times \mathbb{R}^{m-n} = \mathbb{R}^m$$

is an isomorphism. Next we consider the map

$$\Phi := f \times \Theta \colon M \;\to\; N \times \mathbb{R}^{m-n} \subset \mathbb{R}^m.$$

Note that $\mathrm{D}\Phi_P = \mathrm{D}f_P \times \Theta$ is an isomorphism. Thus it follows from the Inverse Mapping Theorem 24.1 that there exists an open neighborhood U of $P \in M$ and an open neighborhood V of $(0, \Theta(P)) \in N \times \mathbb{R}^{m-n}$ such that Φ restricts to a diffeomorphism $\Phi \colon U \to V$. We claim that Φ is a submanifold chart of type (α) for $P \in X = f^{-1}(0)$. In fact this follows immediately from the observation that given $Q \in U$ we have:

$$\Phi(Q) \in \{0\} \times \mathbb{R}^{m-n} \iff f(Q) = 0 \iff Q \in X = f^{-1}(0).$$

Now we consider the case that $P \in \partial M$. In this case we might as well assume that M is an open subset of $\mathbb{H}^m$ with $\partial M = M \cap \partial\, \mathbb{H}^m$. As above we can assume that N is an open subset of $\mathbb{R}^n$ and that $s = 0$. We denote by $\chi \colon \mathbb{R}^m \to \mathbb{R}$ the projection onto the last coordinate. Recall that it follows from the definition of a regular point on page 701 on the boundary, together with the Tangent Space-Isomorphism Proposition 23.16, that the map $\mathrm{D}f_P \colon \widetilde{\mathrm{T}}_P \partial M \to \widetilde{\mathrm{T}}_s N = \mathbb{R}^n$ is an epimorphism. Note that this implies that the map $\mathrm{D}f_P \times \chi \colon \mathbb{R}^m = \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_s N \times \mathbb{R}$ is also an epimorphism. It follows that we can pick a linear map $\Theta \colon \mathbb{R}^m = \widetilde{\mathrm{T}}_P M \to \mathbb{R}^{m-n-1}$ such that the map

$$\mathrm{D}f_P \times \Theta \times \chi \colon \underbrace{\widetilde{\mathrm{T}}_P M}_{=\mathbb{R}^m} \;\to\; \underbrace{\widetilde{\mathrm{T}}_s N}_{=\mathbb{R}^n} \times \mathbb{R}^{m-n-1} \times \mathbb{R}$$

is an isomorphism. Next we consider the map

$$\Phi := f \times \Theta \times \chi \colon M \;\to\; N \times \mathbb{R}^{m-n-1} \times \mathbb{R}_{\geq 0} \;\subset\; \mathbb{H}^m.$$

The remainder of the argument is basically the same as above, except that this time we end up with a submanifold chart of type (β) for P. ⊞

We have thus found for each point in X a submanifold chart of type (α) or (β). This shows that X is an $(m-n)$-dimensional submanifold of M. Furthermore, note that $X = f^{-1}(s)$ is the preimage of a point, hence it is a closed subset of M. It follows from this observation and the fact that we only need submanifold charts of type (α) and (β) that X is in fact a proper submanifold in the sense of the definition on page 525.

(2) We denote by $i\colon X \to M$ the inclusion. Since $f \circ i\colon X \to N$ is a constant map it follows from the discussion on page 631 that for every $P \in X = f^{-1}(s)$ we have the inclusion

$$\operatorname{im}(\mathrm{D}i_P\colon \mathrm{T}_P X \to \mathrm{T}_P M) \;\subset\; \ker(\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_s N).$$

Furthermore we know the following:

- by the Physical Tangent Space-Inclusion Proposition 23.14 we know that $\mathrm{D}i_P$ is a monomorphism,
- by hypothesis we know that $\dim(\mathrm{T}_P M) = m$ and $\dim(\mathrm{T}_s N) = n$, furthermore by (1) we know that $\dim(\mathrm{T}_P X) = m - n$,
- by hypothesis $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_s N$ is an epimorphism.

It follows from the above observations that the above inclusion is in fact an equality.

Finally consider the case that M is a submanifold of some $\mathbb{R}^k$ and that N is a submanifold of some $\mathbb{R}^l$. By the Tangent Space-Isomorphism Proposition 23.16 we have the following commutative diagram:

$$\begin{array}{ccccc}
\mathrm{T}_P X & \xrightarrow{\mathrm{D}i_P} & \mathrm{T}_P M & \xrightarrow{\mathrm{D}f_P} & \mathrm{T}_s N \\
\cong\downarrow\Theta & & \cong\downarrow\Theta & & \cong\downarrow\Theta \\
\widetilde{\mathrm{T}}_P X & \xrightarrow{\mathrm{D}i_P} & \widetilde{\mathrm{T}}_P M & \xrightarrow{\mathrm{D}f_P} & \widetilde{\mathrm{T}}_s N.
\end{array}$$

The statement now follows from the above discussion and the fact, shown in the Physical Tangent Space-Inclusion Proposition 23.3, that the map $\mathrm{D}i_P\colon \widetilde{\mathrm{T}}_P X \to \widetilde{\mathrm{T}}_P M$ is an inclusion.

(3)

(a) We leave it to the reader to verify, using the chart from (1), that the given orientations on the tangent spaces $\mathrm{T}_P X$ do indeed define an orientation on the smooth manifold X.

(b) We need to prove that the two orientations on $\partial f^{-1}(s) = (f_\partial)^{-1}(s)$ agree. Thus let $P \in \partial f^{-1}(s)$. We work with the following orientations:

$\mathrm{T}_P(f^{-1}(s))$	with the orientation from (3a) applied to $f\colon M \to N$
$\mathrm{T}_P\,\partial(f^{-1}(s))$	with the boundary orientation from page 689
$\mathrm{T}_P(f_\partial)^{-1}(s))$	with the orientation from (3a) applied to $f_\partial\colon \partial M \to N$
$\mathrm{T}_P M$	with the given orientation
$\mathrm{T}_P\,\partial M$	with the boundary orientation from page 689.

To simplify the notation we view $\mathrm{T}_P f^{-1}(s)$ as a vector subspace of $\mathrm{T}_P M$. We pick an outward pointing vector $o \in \mathrm{T}_P f^{-1}(s)$. It follows from Exercise 23.8 that

o, viewed as a vector in $\mathrm{T}_P M$, is also outward pointing. Now let $u_1, \ldots, u_{m-n-1}$ be a basis of $\mathrm{T}_P(\partial f^{-1}(s)) = \mathrm{T}_P(f_\partial)^{-1}(s)$. We see:

$$\begin{array}{rll} & u_1, \ldots, u_{m-n-1} & \text{is a positive basis of } \mathrm{T}_P\, \partial(f^{-1}(s)) \\ \iff & o, u_1, \ldots, u_{m-n-1} & \text{is a positive basis of } \mathrm{T}_P f^{-1}(s) \\ \iff & o, u_1, \ldots, u_{m-n-1}, \widetilde{v}_1, \ldots, \widetilde{v}_n & \text{is a positive basis of } \mathrm{T}_P M \\ \iff & u_1, \ldots, u_{m-n-1}, \widetilde{v}_1, \ldots, \widetilde{v}_n & \text{is a positive basis of } \mathrm{T}_P\, \partial M \\ \iff & u_1, \ldots, u_{m-n-1} & \text{is a positive basis of } \mathrm{T}_P(f_\partial)^{-1}(s) \end{array}$$

(4) Let K be a compact subset of M. Since $X = f^{-1}(s)$ is a closed subset of M we know $X \cap K$ is a closed subset of K, hence $X \cap K$ is compact by the Compact-Closed Lemma 1.21. ■

26.4. **Matrix groups as smooth manifolds.** In this section we will see that several popular matrix groups are in fact smooth manifolds.

Convention.

(1) Given $m, n \in \mathbb{N}$ we will make the identification

$$\begin{array}{rcl} \mathrm{M}(m \times n, \mathbb{R}) & \to & \mathbb{R}^{m \cdot n} \\ A = (a_{ij}) & \mapsto & (a_{11}, \ldots, a_{1n}, \ldots, a_{m1}, \ldots, a_{mn}). \end{array}$$

In particular, given a smooth submanifold M of $\mathrm{M}(m \times n, \mathbb{R})$ we can consider the physical tangent space

$$\widetilde{\mathrm{T}}_P M \ \subset\ \mathrm{M}(m \times n, \mathbb{R}).$$

(2) We make the usual identification $\mathbb{C} = \mathbb{R}^2$ and combining these identifications we will identify $\mathrm{M}(m \times n, \mathbb{C})$ with $= \mathbb{C}^{m \cdot n} = \mathbb{R}^{2m \cdot n}$.

(3) Throughout this section we use the Tangent Space-Isomorphism Proposition 23.16, when appropriate, to identify the abstract tangent spaces $\mathrm{T}_P M$ with the physical tangent spaces $\widetilde{\mathrm{T}}_P M$.

We just saw made the identification $\mathrm{M}(m \times n, \mathbb{R}) = \mathbb{R}^{m \cdot n}$ which allows us to view $\mathrm{M}(m \times n, \mathbb{R})$ as an $m \cdot n$-dimensional smooth manifold. We can thus view the open subset $\mathrm{GL}(n, \mathbb{R}) = \{A \in \mathrm{M}(n \times n, R) \,|\, \det(A) \neq 0\}$ also as an n^2-dimensional smooth manifold. The next results show that other matrix groups are also smooth manifolds, albeit in a less trivial way.

Proposition 26.5. (Matrix Group-Smooth Manifold Proposition) Let $n \in \mathbb{N}$.

(1) The special linear group

$$\mathrm{SL}(n, \mathbb{R}) \ = \ \{A \in \mathrm{M}(n \times n, \mathbb{R}) \,|\, \det(A) = 1\}$$

is an orientable proper (n^2-1)-dimensional submanifold of $\mathrm{M}(n \times n, \mathbb{R})$. Furthermore for every $A \in \mathrm{SL}(n, \mathbb{R})$ we have

$$\widetilde{\mathrm{T}}_A\, \mathrm{SL}(n, \mathbb{R}) \ = \ A \cdot \{B \in \mathrm{M}(n \times n, \mathbb{R}) \,|\, \mathrm{tr}(B) = 0\}.$$

(2) The special linear group

$$\mathrm{SL}(n, \mathbb{C}) \ = \ \{A \in \mathrm{M}(n \times n, \mathbb{C}) \,|\, \det(A) = 1\}$$

is an orientable proper $2(n^2-1)$-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{C})$. Furthermore for every $A\in \mathrm{SL}(n,\mathbb{C})$ we have

$$\widetilde{\mathrm{T}}_A\,\mathrm{SL}(n,\mathbb{C}) \;=\; A\cdot\{B\in \mathrm{M}(n\times n,\mathbb{C})\mid \mathrm{tr}(B)=0\}.$$

In the proof of the Matrix Group-Smooth Manifold Proposition 26.5 we will make use of the following lemma.

Lemma 26.6. Given any smooth map $\gamma\colon(-\epsilon,\epsilon)\to \mathrm{M}(n\times n,\mathbb{R})$ with $\gamma(0)\in \mathrm{GL}(n,\mathbb{R})$ we have
$$\tfrac{d}{dt}\det(\gamma(t))\big|_{t=0} \;=\; \det(\gamma(0))\cdot \mathrm{tr}\left(\gamma(0)^{-1}\cdot\gamma'(0)\right).$$

Proof of Lemma 26.6. We start out with the following claim.

Claim. The map $\det\colon \mathrm{M}(n\times n,\mathbb{R})\to\mathbb{R}$ is smooth and the differential at id is given by the map
$$\begin{array}{rcl}\mathrm{M}(n\times n,\mathbb{R}) & \to & \mathbb{R}\\ B & \mapsto & \mathrm{tr}(B).\end{array}$$

Proof. By the Leibniz formula the determinant of a matrix is a polynomial in the n^2 entries. It follows that the map $\det\colon \mathrm{M}(n\times n,\mathbb{R})\to\mathbb{R}$ is smooth. Next let $B=(b_{ij})\in \mathrm{M}(n\times n,\mathbb{R})$. Note that
$$\mathrm{D}\det_{\mathrm{id}}(B) \;=\; \tfrac{d}{dt}\det(\mathrm{id}+t\cdot B)\big|_{t=0}.$$
We now perform the following calculation:

$$\begin{aligned}\det(\mathrm{id}+t\cdot B) &= \sum_{\sigma\in S_n}(-1)^{\mathrm{sign}(\sigma)}\cdot\prod_{i=1}^{n}(\underbrace{\delta_{i\sigma(i)}}_{\substack{\text{Kronecker}\\ \text{delta}}}+t\cdot b_{i\sigma(i)})\\ &\quad\uparrow \text{ Laplace expansion}\\ &= \underbrace{\prod_{i=1}^{n}(1+t\cdot b_{ii})}_{\text{corresponds to }\sigma=\mathrm{id}} + \sum_{\mathrm{id}\neq\sigma\in S_n}(-1)^{\mathrm{sign}(\sigma)}\cdot\underbrace{\prod_{i=1}^{n}(\delta_{i\sigma(i)}+t\cdot b_{i\sigma(i)})}_{\substack{\text{since id}\neq\sigma\text{ we have }i\neq\sigma(i)\\ \text{for at least two } i\in\{1,\dots,n\}\\ \text{which implies that we can factor out } t^2}}\\ &= \prod_{i=1}^{n}(1+t\cdot b_{ii})+\text{terms of order at least } t^2\end{aligned}$$

It is now clear that if we take the derivative at $t=0$, then we obtain the trace of B. ⊞

Now let $\gamma\colon(-\epsilon,\epsilon)\to\mathrm{M}(n\times n,\mathbb{R})$ be a smooth map with $A:=\gamma(0)\in\mathrm{GL}(n,\mathbb{R})$. We see that
$$\tfrac{d}{dt}\det(\gamma(t))\big|_{t=0} \;=\; \det(A)\cdot\tfrac{d}{dt}\det(A^{-1}\cdot\gamma(t))\big|_{t=0} \;\underset{\substack{\uparrow\\ \text{by the Chain Rule 19.10 and the above claim}}}{=}\; \det(A)\cdot\mathrm{tr}(A^{-1}\cdot\gamma'(0)).$$
■

Proof of the Matrix Group-Smooth Manifold Proposition 26.5.

(1) First we show that $\mathrm{SL}(n,\mathbb{R})$ is an orientable proper (n^2-1)-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{R})$. By the Regular Value Theorem 26.4 it suffices to show that 1 is a regular value of the smooth map $\det\colon \mathrm{M}(n\times n,\mathbb{R})\to\mathbb{R}$. In fact we will show that any matrix $A\in\mathrm{M}(n\times n,\mathbb{R})$ with $\det(A)\neq 0$ is a regular point. This in turn follows from the observation that
$$\tfrac{d}{dt}\det((1+t)\cdot A)\big|_{t=0} \;=\; \tfrac{d}{dt}(1+t)^n\cdot\det(A)\big|_{t=0} \;=\; (n\cdot(1+t)^{n-1}\cdot\det(A))\big|_{t=0} = \underbrace{n\cdot\det(A)}_{\neq 0}.$$

Next let $A \in \mathrm{SL}(n,\mathbb{R})$. If $\gamma\colon (-\epsilon,\epsilon) \to \mathrm{SL}(n,\mathbb{R})$ is a smooth path with $\gamma(0) = A$, then it follows immediately from Lemma 26.6 that $\mathrm{tr}(A^{-1}\cdot\gamma'(0)) = 0$. In other words, we see that

$$\widetilde{\mathrm{T}}_A \,\mathrm{SL}(n,\mathbb{R}) \subset \{B \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, \mathrm{tr}(A^{-1}\cdot B) = 0\} = A\cdot\{B \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, \mathrm{tr}(B) = 0\}.$$

But both are vector spaces of dimension $n^2 - 1$, so we see that equality holds.

(2) First we show that $\mathrm{SL}(n,\mathbb{C}) = \{A \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, \det(A) = 1\}$ is an orientable proper $2(n^2-1)$-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{C})$. This time we need to show that every matrix $A \in \mathrm{M}(n\times n,\mathbb{C})$ with $\det(A) \neq 0$ is in fact a regular point of $\det\colon \mathrm{M}(n\times n,\mathbb{C}) \to \mathbb{C} = \mathbb{R}^2$. Similarly to (1) we calculate that

$$\tfrac{d}{dt}\det((1+\mathrm{i}t)\cdot A)\big|_{t=0} = \tfrac{d}{dt}(1+\mathrm{i}t)^n\cdot\det(A)\big|_{t=0} = \mathrm{i}\cdot n\cdot\det(A).$$

Together with the calculation in (1) this shows that $\mathrm{D}\det_A\colon \mathrm{M}(n\times n,\mathbb{C}) \to \mathbb{C}$ is indeed an epimorphism. The remainder of the argument is similarly an adaptation of the argument provided in (1). We leave it to the reader to fill in the details. ■

The following proposition deals with much more interesting matrix groups.

Proposition 26.7. (Matrix Group-Smooth Manifold Proposition II) Let $n \in \mathbb{N}$.

(1) The set
$$\mathrm{O}(n) = \{A \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, A^TA = \mathrm{id}\}$$
of orthogonal matrices is an orientable proper $\frac{1}{2}n(n-1)$-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{R}) = \mathbb{R}^{n^2}$. Furthermore for every $A \in \mathrm{O}(n)$ we have
$$\widetilde{\mathrm{T}}_A\,\mathrm{O}(n) = A\cdot\{B \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, B = -B^T\}.$$
The analogous statements also hold for the component $\mathrm{SO}(n)$ of $\mathrm{O}(n)$.

(2) The set
$$\mathrm{U}(n) = \{A \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, \overline{A}^TA = \mathrm{id}\}$$
of unitary matrices is similarly an orientable proper n^2-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2}$. Furthermore for every $A \in \mathrm{U}(n)$ we have
$$\widetilde{\mathrm{T}}_A\,\mathrm{U}(n) = A\cdot\{B \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, B = -\overline{B}^T\}.$$

(3) The set
$$\mathrm{SU}(n) = \{A \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, \overline{A}^TA = \mathrm{id} \text{ and } \det(A) = 1\}$$
of special unitary matrices is an orientable proper (n^2-1)-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2}$. Furthermore for every $A \in \mathrm{SU}(n)$ we have
$$\widetilde{\mathrm{T}}_A\,\mathrm{SU}(n) = A\cdot\{B \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, B = -\overline{B}^T \text{ and } \mathrm{tr}(B) = 0\}.$$

All of the above examples, viewed as smooth manifolds in their own right, are closed.

Proof of the Matrix Group-Smooth Manifold Proposition 26.7 for $\mathrm{O}(n)$**.** We start out our proof of the Matrix Group-Smooth Manifold Proposition 26.7 (1) with the following claim.

Claim.

(i) The set
$$\mathrm{Sym}(n,\mathbb{R}) = \{B \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, B^T = B\} = \{(b_{ij}) \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, b_{ij} = b_{ji}\}$$

is a submanifold of $\mathrm{M}(n\times n,\mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $\frac{1}{2}n(n+1)$.

(ii) The map
$$\begin{array}{rccc} f\colon & \mathrm{M}(n\times n,\mathbb{R}) & \to & \mathrm{Sym}(n,\mathbb{R}) \\ & A & \mapsto & A^TA \end{array}$$
is smooth and id is a regular value.

Proof. Statement (i) follows immediately from Lemma 23.1 (2). We turn to the proof of Statement (ii). It should be clear that f is smooth and that f does indeed take values in $\mathrm{Sym}(n,\mathbb{R})$. Furthermore by definition we have $\mathrm{O}(n) = f^{-1}(\mathrm{id})$. So it remains to show that id is a regular value.

In the following we again use Lemma 23.1 (2) which implies that the physical tangent spaces of the submanifolds $\mathrm{Sym}(n,\mathbb{R})$ and $\mathrm{M}(n\times n,\mathbb{R})$ are just given by these vector subspaces. So let $A\in\mathrm{M}(n\times n,\mathbb{R})$ with $A^TA=\mathrm{id}$ and let $C\in \mathrm{T}_{\mathrm{id}}\,\mathrm{Sym}(n,\mathbb{R}) = \mathrm{Sym}(n,\mathbb{R})$. We need to show that there exists a B in $\mathrm{T}_A\,\mathrm{M}(n\times n,\mathbb{R}) = \mathrm{M}(n\times n,\mathbb{R})$ with $\mathrm{D}f_A(B) = C$.

We start out with the following little calculation: Given $B\in\mathrm{M}(n,\times n,\mathbb{R})$ we have

$$\begin{aligned} \tfrac{d}{dt}f(A+tB)\big|_{t=0} &= \tfrac{d}{dt}(A^T+tB^T)\cdot(A+tB)\big|_{t=0} \\ &= \tfrac{d}{dt}\big(A^TA+tA^TB+tB^TA+t^2B^TB\big)\big|_{t=0} \;=\; A^TB+B^TA. \end{aligned}$$

Using that $A^T\cdot A = \mathrm{id}$ and $C = C^T$ it is now easy to see that $B := \frac{1}{2}A\cdot C$ satisfies $\mathrm{D}f_A(B) = C$. ⊞

It follows from the claim, together with the Regular Value Theorem 26.4, that $\mathrm{O}(n)$ is an orientable proper submanifold of $\mathrm{M}(n\times n,\mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $n^2-\frac{1}{2}n(n+1) = \frac{1}{2}n(n-1)$. Since $\mathbb{R}^{n^2}$ has no boundary and since $\mathrm{O}(n)$ is a proper submanifold we see that the boundary of $\mathrm{O}(n)$ is also empty. Finally note that in the Matrix Group Lemma 2.36 (3) we showed that $\mathrm{O}(n)$ is compact. These last two observations imply that $\mathrm{O}(n)$ is in fact a closed smooth manifold.

It remains to prove the following claim.

Claim. For every $A\in\mathrm{O}(n)$ we have the following equality:
$$\widetilde{\mathrm{T}}_A\,\mathrm{O}(n) \;=\; A\cdot\{B\in\mathrm{M}(n\times n,\mathbb{R})\,|\,B=-B^T\}.$$

Proof. Note that both sides are vector subspaces of $\mathrm{M}(n\times n,\mathbb{R})$ of dimension $\frac{1}{2}n(n-1)$. Thus it suffices to prove the "$\subset$"-inclusion. Let $X\in\widetilde{\mathrm{T}}_A\,\mathrm{O}(n)$. We pick a smooth map $\gamma\colon(-\epsilon,\epsilon)\to\mathrm{O}(n)$ with $\gamma(0)=A$ and $\gamma'(0)=X$. We make the following observations:

$$\begin{aligned} \gamma(t)\in\mathrm{O}(n)\text{ for all }t &\implies \gamma(t)^T\cdot\gamma(t) = \mathrm{id}\text{ for all }t \\ &\implies (\gamma(t)^T)'\cdot\gamma(t)+\gamma(t)^T\cdot\gamma(t)' = 0\text{ for all }t \\ &\implies X^T\cdot A + A^T\cdot X = 0 \\ &\implies (A^T\cdot X)^T + A^T\cdot X = 0 \\ &\implies X = \underbrace{A\cdot A^T}_{=\mathrm{id},\text{ since }A\in\mathrm{O}(n)}\cdot X \text{ where } B := A^T\cdot X \text{ satisfies } B=-B^T. \end{aligned}$$

■

Proof of the Matrix Group-Smooth Manifold Proposition 26.7 for $\mathrm{U}(n)$ and $\mathrm{SU}(n)$. The proof for $\mathrm{U}(n)$ is almost verbatim the same as the proof for $\mathrm{O}(n)$. The proof for $\mathrm{SU}(n)$ follows from combining the ideas for the proof of $\mathrm{U}(n)$ with the ideas for the proof of the Matrix Group-Smooth Manifold Proposition 26.5 (2) where we showed that $\mathrm{SL}(n,\mathbb{C})$

is an (n^2-1)-dimensional submanifold of $\mathrm{M}(n\times n,\mathbb{R})$. We will deal with $\mathrm{SL}(n,\mathbb{C})$ in Exercise 26.12. We leave the case $\mathrm{SL}(n,\mathbb{C})$ to the reader. ■

Exercises for Chapter 26.

Exercise 26.1. Let M be a closed smooth manifold and let N be a connected smooth manifold. Let $f\colon M\to N$ be a map. Show that if f has no critical values, then f is surjective.
Hint. First consider the case that $\dim(M)=\dim(N)$.

Exercise 26.2. Let $p(z)=a_0+a_1z+\cdots+a_nz^n$ be a complex polynomial of degree n. We consider the map

$$\begin{array}{rcl} p\colon \mathbb{C} & \to & \mathbb{C} \\ w & \mapsto & p(w). \end{array}$$

Show that there exists a finite subset $Y\subset\mathbb{C}$ such that for every $z\notin Y$ we have the equality $\#p^{-1}(w)=n$.

Exercise 26.3. We consider

$$M := \{(x,y,z)\in\mathbb{R}^3 \mid x^2-y^2-z^2=1\} \qquad \text{and} \qquad N := \{(x,y,z)\in\mathbb{R}^3 \mid x^2+y^2-z^2=1\}.$$

(a) Show that M and N are 2-dimensional smooth submanifolds of $\mathbb{R}^3$.
(b) Sketch M and N.

Exercise 26.4. Let A be a real symmetric $n\times$n-matrix.

(a) Show that $\{v\in\mathbb{R}^n \mid \langle v, A\cdot v\rangle = 1\}$ is an $(n-1)$-dimensional smooth submanifold of $\mathbb{R}^n$.
(b) Under what condition on the eigenvalues of A is the submanifold in (a) compact?

Exercise 26.5. We consider

$$T := \{(x,y,z)\in\mathbb{R}^3 \mid (\sqrt{x^2+y^2}-2)^2+z^2=1\}.$$

(a) Show that T is rotationally symmetric around the z-axis.
(b) Provide a sketch of T.
(c) Show that T is a submanifold of $\mathbb{R}^3$.
(d) In Exercise 24.15 we showed that the map

$$\begin{array}{rcl} f\colon \mathbb{R}^2/(2\pi\mathbb{Z})^2 & \to & \mathbb{R}^3 \\ (\varphi,\theta) & \mapsto & \underbrace{\begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\text{rotation around the } z\text{-axis}} \cdot \underbrace{\begin{pmatrix} 2+\sin(\theta) \\ 0 \\ \cos(\theta) \end{pmatrix}}_{\substack{\text{describes a circle} \\ \text{in the } xz\text{-plane}}} \end{array}$$

is a smooth embedding. Show that T is diffeomorphic to $f(\mathbb{R}^2/(2\pi\mathbb{Z})^2)$.

Exercise 26.6. Let M be an m-dimensional smooth manifold and let $f\colon M\to\mathbb{R}$ be a smooth function.

(a) Let $s \in \mathbb{R}$ be a regular value of f such that for each component C of ∂M we have either $f^{-1}(s) \cap C = C$ or $f^{-1}(s) \cap C = \varnothing$. Show that $X := f^{-1}((-\infty, s])$ is a smooth codimension-zero submanifold of M with $\partial_0 X = f^{-1}(s) \setminus \partial M$ and $\partial_1 X = X \cap \partial M$.

(b) Let $s < t \in \mathbb{R}$ be regular values such that for each component C of ∂M we have either $f^{-1}(s) \cap C = C$ or $f^{-1}(s) \cap C = \varnothing$ and such that for each component C of ∂M we have either $f^{-1}(t) \cap C = C$ or $f^{-1}(t) \cap C = \varnothing$. Show that $X := f^{-1}([s,t])$ is a smooth codimension-zero submanifold of M with $\partial_0 X = (f^{-1}(s) \cup f^{-1}(t)) \setminus \partial M$ and $\partial_1 X = X \cap \partial M$.

Exercise 26.7. Let $f\colon \mathbb{R}^n \to \mathbb{R}$ be a smooth map and let $z \in \mathbb{R}$ be a regular value. We set $M := f^{-1}(z)$. Given $P \in \mathbb{R}^n$ we denote by

$$\operatorname{grad} f_P \;:=\; (\mathrm{D}f_P)^T \;=\; \big(\tfrac{\partial f}{\partial x_1}\big|_P, \ldots, \tfrac{\partial f}{\partial x_n}\big|_P\big) \;\in\; \mathbb{R}^n$$

the gradient. Show that for every $P \in M$ we have

$$\widetilde{\mathrm{T}}_P M \;=\; (\operatorname{grad} f_P)^\perp \;=\; \{v \in \mathbb{R}^n \,|\, \langle v, \operatorname{grad} f_P\rangle = 0\}.$$

Exercise 26.8. Let $m, n \in \mathbb{N}$.

(a) Show that

$$\mathrm{O}(m,n) \;:=\; \text{set of } n\text{-tuples of orthonormal vectors of } \mathbb{R}^m$$

is a submanifold of $\mathrm{M}(m \times n, \mathbb{R})$.

(b) Given $A \in \mathrm{O}(m,n)$ determine $\widetilde{\mathrm{T}}_A \mathrm{O}(m,n) \subset \mathrm{M}(m \times n, \mathbb{R})$.

Exercise 26.9. Let $A \in \mathrm{M}(n \times n, \mathbb{R})$ be a symmetric matrix and let $v \in \mathbb{R} \setminus \{0\}$. Show that the quadric

$$M \;:=\; \{x \in \mathbb{R}^n \,|\, \langle x, A \cdot x\rangle = v\}$$

is an $(n-1)$-dimensional submanifold of $\mathbb{R}^n$.

Exercise 26.10. Let $d \in \mathbb{N}_0$. Show that

$$M_d \;:=\; \Big\{(z_0, \ldots, z_n) \in \mathbb{C}^{n+1} \,\Big|\, z_0^d + \cdots + z_n^d = 0 \text{ and } \sum_{k=0}^{n} |z_i|^2 = 2\Big\}$$

is a $(2n-1)$-dimensional submanifold of $\mathbb{C}^{2n+1}$.
Remark. These smooth manifolds are sometimes called *Brieskorn manifolds*.

Exercise 26.11. Any matrix $A \in \mathrm{M}(n \times n, \mathbb{C})$ defines an endomorphism of $\mathbb{C}^n = \mathbb{R}^{2n}$. Thus we can view A also as a matrix in $\mathrm{M}(2n \times 2n, \mathbb{R})$.

(a) Show that with the above convention $\mathrm{U}(n)$ is a subgroup of $\mathrm{O}(2n)$.

(b) Show that $\mathrm{U}(n)$ is a submanifold of $\mathrm{O}(2n)$.

Exercise 26.12.

(a) Show that

$$\mathrm{SU}(n) \;=\; \big\{A \in \mathrm{M}(n \times n, \mathbb{C}) \,\big|\, \overline{A}^T A = \mathrm{id} \text{ and } \det(A) = 1\big\}$$

is a smooth manifold of dimension $n^2 - 1$.

(b) Show that for every $A \in \mathrm{SU}(n)$ we have

$$\widetilde{\mathrm{T}}_A \mathrm{SU}(n) \;=\; A \cdot \{B \in \mathrm{M}(n \times n, \mathbb{C}) \,|\, B = -\overline{B}^T \text{ and } \operatorname{tr}(B) = 0\}.$$

Exercise 26.13. We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}^{n+1} & \to & \mathbb{R} \\ (x_1, \dots, x_{n+1}) & \mapsto & x_1^2 + \dots + x_{n+1}^2. \end{array}$$

We equip $\mathbb{R}^{n+1}$ and $\mathbb{R}$ with the standard orientations. For which $n \in \mathbb{N}$ does the orientation on the sphere $S^n = f^{-1}(1)$ that is defined by the Regular Value Theorem 26.4 (3b) agree with the standard orientation on S^n that we introduced on page 681.

Exercise 26.14.

(a) Let $A \subset \mathrm{M}(m \times n, \mathbb{R})$. Show that A has rank k if and only if there exist k columns and k rows such that the $k \times k$-matrix that is given by entries corresponding to these rows and columns has non-zero determinant.

(b) Show that $X := \{A \in \mathrm{M}(m \times n, \mathbb{R}) \mid A \text{ has rank } k\}$ is a submanifold of $\mathrm{M}(m \times n, \mathbb{R})$ of dimension $(m-k) \cdot (n-k)$.
Hint. Construct explicit charts around each $A \in X$. To preserve sanity it is helpful to start with $A \in X$ which has the property that the top-left $k \times k$-submatrix has non-zero determinant.

Exercise 26.15. Let $k \in \mathbb{N}$ and let M be a smooth manifold with empty boundary. We refer to

$$\mathrm{Conf}_k(M) \;:=\; \{(x_1, \dots, x_k) \in M^k \mid \text{ for all } i \neq j \text{ we have } x_i \neq x_j\}$$

as the *configuration space of k points in M*.

(a) Show that $\mathrm{Conf}_k(M)$ is an open subset of M. This shows that $\mathrm{Conf}_k(M)$ is a smooth manifold of dimension $\dim(M) \cdot k$.

(b) We now restrict ourselves to $k = 3$ and $M = \mathbb{R}^2$.

(i) We consider the map

$$\begin{array}{rcl} f\colon \mathrm{Conf}_3(\mathbb{R}^2) & \to & \mathbb{R} \\ (x_1, x_2, x_3) & \mapsto & \det \underbrace{(x_2 - x_1 \;\; x_3 - x_1)}_{2 \times 2\text{-matrix}}. \end{array}$$

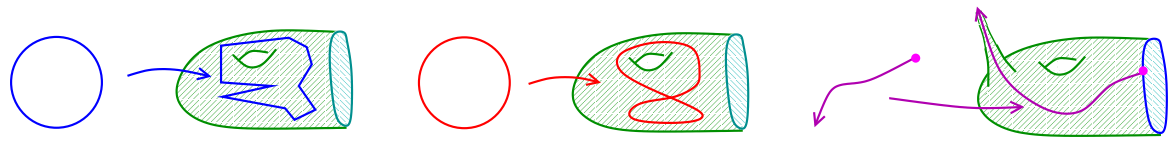
Show that 0 is a regular value of f.

(ii) We say that $(x_1, x_2, x_3) \in \mathrm{Conf}_3(\mathbb{R}^2)$ are collinear if there exists a line that contains all three points. Show that the set of collinear (x_1, x_2, x_3) is a submanifold of $\mathrm{Conf}_3(\mathbb{R}^2)$ of dimension 5.

27. The Euclidean Embedding Theorem

27.1. **The statement of the Euclidean Embedding Theorem.** For the reader's convenience we recall the following definitions from pages 152, 651 and 650.

Definition.



(1) A map $\varphi\colon Y \to X$ between topological spaces is called an embedding if $\varphi\colon Y \to \varphi(Y)$ is a homeomorphism. (Here we view $\varphi(Y)$ as a topological space equipped with the subspace topology coming from X.)

(2) A map $\varphi\colon N \to M$ between two smooth manifolds is called an immersion if the following conditions are satisfied:
   (a) φ is smooth,
   (b) for each $P \in N$ the differential $\mathrm{D}\varphi_P\colon \mathrm{T}_P N \to \mathrm{T}_{\varphi(P)} M$ is a monomorphism,
   (c) If $\partial M \neq \varnothing$, then we require that also the following conditions are satisfied:
      (i) For each $P \in N \setminus \partial N$ we have $\varphi(P) \in M \setminus \partial M$.
      (ii) For each $P \in \partial N$ with $\varphi(P) \in \partial M$ the image $\mathrm{D}\varphi_P(\mathrm{T}_P N)$ is *not* contained in $\mathrm{T}_{\varphi(P)}(\partial M)$.
      (iii) For every component C of ∂N we have $\varphi(C) \subset \partial M$ or $\varphi(C) \subset M \setminus \partial M$.

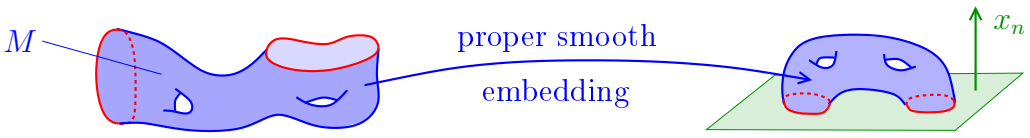
   An immersion that also satisfies the following extra condition
   (d) $\varphi\colon N \to M$ is an embedding,
   is called a smooth embedding.

(3) Let M and N be two topological manifolds. A map $\varphi\colon N \to M$ is called proper if the following two conditions are satisfied:[281]
   (a) $\varphi^{-1}(\partial M) = \partial N$,
   (b) $\varphi(N)$ is a closed subset of M.

(4) Given $n \in \mathbb{N}$ we write $\mathbb{H}^n := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\}$.

embedding immersion proper smooth embedding

We can now formulate the main theorem of this chapter.



Theorem 27.1. (Euclidean Embedding Theorem)

(1) Given any topological manifold M there exists an $n \in \mathbb{N}$ and a proper embedding $M \to \mathbb{H}^n$.

(2) Given any smooth manifold M there exists an $n \in \mathbb{N}$ and a proper smooth embedding $M \to \mathbb{H}^n$.

We will provide the proof of the Euclidean Embedding Theorem 27.1 in the following sections.

[281] On page 651 we gave a short discussion of the unfortunate fact that the adjective "proper" is oversubscribed.

It is already worth pointing out that the proof of the Euclidean Embedding Theorem 27.1 breaks into two cases:

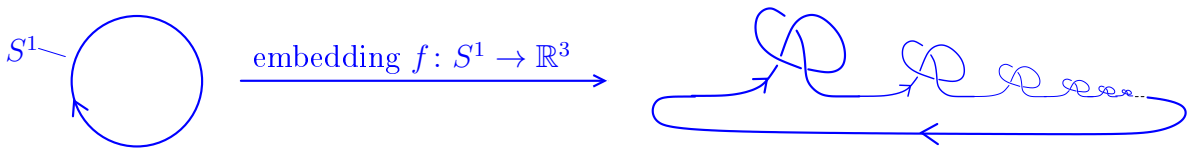
(1) In the compact case the proof of the Euclidean Embedding Theorem 27.1 is fairly straightforward: using a partition of unity subordinate to a finite atlas it is fairly straightforward to cobble together an argument. We refer to Section 27.2 for full details.

(2) The non-compact case is significantly harder. Our approach relies on the notion of the covering dimension that we had developed in Chapter 11. In Section 27.3 we will consider the covering dimension of topological manifolds. In particular in the Covering Dimension-of-Manifolds Proposition 27.7 we will show that the covering dimension of an n-dimensional topological manifold is $\leq n$. We will use this fact, together with the Covering Dimension Refinement Theorem 11.12, to show in the Small Atlas Proposition 27.8 that every n-dimensional topological manifold admits an atlas consisting of $\leq n+1$ charts. Using this result, together with the Covering Dimension Refinement Theorem 11.12, it is then straightforward to show that every non-compact topological manifolds admits a proper embedding into some $\mathbb{H}^n$. Furthermore the last two statements also work for smooth manifolds and provide us with a smooth atlas consisting of $\leq n+1$ charts and we obtain a proper smooth embedding $M \to \mathbb{H}^n$.

Remark. The fact that every non-compact smooth manifold (at least with empty boundary) admits a proper smooth embedding into some $\mathbb{H}^n$ is also proved, using a different approach, in [**Wall2016**, Corollary 4.7.8] and [**Lee2002**, Theorem 6.15]. We will sketch the argument provided in [**Lee2002**, Theorem 6.15] later on in Exercise **??**.

In the remainder of this section we take the Euclidean Embedding Theorem 27.1 for granted and we discuss a few consequences.

Corollary 27.2. (Diffeomorphic-to-Euclidean Submanifold Corollary) Given any smooth manifold M there exists an $n \in \mathbb{N}$ such that M is diffeomorphic to a proper smooth submanifold of $\mathbb{H}^n$.



Proof. Let M be a smooth manifold. By the Euclidean Embedding Theorem 27.1 there exists an $n \in \mathbb{N}$ and a proper smooth embedding $M \to \mathbb{H}^n$. Furthermore by the Smooth Embedding Theorem 24.10 we know that $\varphi(N)$ is a proper n-dimensional smooth submanifold of $\mathbb{H}^n$ and that the map $\varphi\colon N \to \varphi(N)$ is a diffeomorphism. ■

Remark. Note that the logic of the Diffeomorphic-to-Euclidean Submanifold Corollary 27.2 does *not* apply to topological manifolds. For example let us consider the embedding $f\colon S^1 \to \mathbb{R}^3$ that is shown in the figure below and that we encountered already on page 659. The map $f\colon S^1 \to \mathbb{R}^3$ is an embedding but, as we will see in Proposition 124.15, the image

$f(S^1)$ is not a topological submanifold of $\mathbb{R}^3$. But it turns out that the situation can mostly be fixed:

(1) Let X and Y be topological manifolds with $\dim(Y) \geq \dim(X) + 3$. It was shown by Richard Miller [**MillR1972**, Theorem 5] (see also the work of Aleksei Chernavskii [**Cherna1969b**, Theorem 1] and M. A. Stan'ko [**Stan1973**, Theorem 1]) that given any embedding $f\colon X \to Y$, given any metric d on Y and given any $\epsilon > 0$ there exists an embedding $g\colon X \to Y$ such that $g(X)$ is a submanifold of Y and such that for all $x \in X$ we have $d(f(x), g(x)) < \epsilon$. It follows from this fact, together with the Euclidean Embedding Theorem 27.1, Exercise 2.62 and the Proper-Closed Proposition 2.43 that every topological manifold of dimension ≥ 2 is homeomorphic to a topological submanifold of $\mathbb{R}^{2n+1}$ that is a closed subset of $\mathbb{R}^{2n+1}$.[282]

(2) If X is a 1-dimensional topological manifold, then we know by the Topological 1-Dimensional Manifold Classification Theorem 22.1 that each component of X is homeomorphic to one of S^1, $[0,1]$, $[0,1)$ or $(0,1)$. Since topological manifolds are second-countable they have, see Exercise 9.1, only countably many components. So it is straightforward to show that X is homeomorphic to a proper submanifold of $\mathbb{H}^2$.

Corollary 27.3. As usual we denote by $\mathcal{SmMfd}$ the category of smooth manifolds and we denote by $\mathcal{SmMfd}_{\mathbb{R}^n}$ the category of smooth submanifolds of some $\mathbb{R}^n$. The functor $\mathcal{SmMfd}_{\mathbb{R}^n} \to \mathcal{SmMfd}$ that is given by

$$\begin{array}{rcl} M & \mapsto & (M, \text{standard smooth structure as defined on page 552}) \\ (f\colon M \to N) & \mapsto & (f\colon M \to N) \end{array}$$

is a weak equivalence of categories in the sense of the definition on page 207.

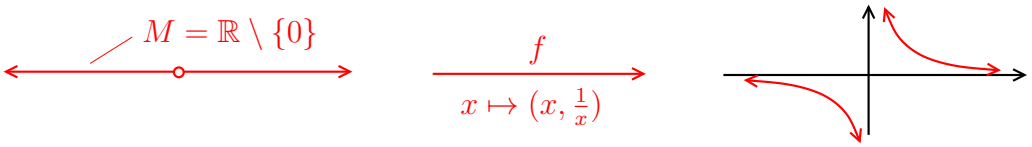
Proof. The Diffeomorphic-to-Euclidean Submanifold Corollary 27.2 says that the given functor is essentially surjective in the sense of the definition on page 207. The remaining conditions of the Weak Equivalence of Categories Proposition 3.11 are satisfied basically by definition. Thus we obtain from said proposition that the functor is a weak equivalence of categories. ■

In the Manifold Metrization Proposition 18.10 we showed, using the mighty Urysohn Metrization Theorem 9.4 and the less mighty the Completely Metrizable Criterion Proposition 10.8 that every topological manifold is completely metrizable. In the following proposition we will use the Euclidean Embedding Theorem 27.1 to provide a new proof of this statement, that does not rely on the Urysohn Metrization Theorem 9.4. In fact for a smooth manifold M we can even strengthen the earlier result, namely we can now find

[282] The literature does not give control over the behavior of the boundary so we cannot arrange that we get a proper embedding of $\mathbb{R}^{2n+1}$. This burning issue could surely be resolved if somebody went back to the original literature and upgraded the results.

a metric $d\colon M \times M \to \mathbb{R}_{\geq 0}$ that is smooth away from the "diagonal", i.e. away from $\{(x,x) \in M \times M \,|\, x \in M\}$.

Proposition 27.4. (Manifold Metrization Proposition)



(1) Every topological manifold M is *completely* metrizable, i.e. there exists a *complete* metric d on M such that the given topology agrees with the topology coming from d.
(2) Every smooth manifold M admits a complete metric $d\colon M \times M \to \mathbb{R}_{\geq 0}$ such that the restriction of d to the open subset $\{(x,y) \in M \times M \,|\, x \neq y\}$ is smooth.

Remark. As we will see shortly, the Manifold Metrization Proposition 27.4 (1) is a straightforward consequence of the Euclidean Embedding Theorem 27.1 (1). As we mentioned above, for compact topological manifolds we provide in Section 27.2 an elementary proof of the Euclidean Embedding Theorem 27.1. On the other hand, for non-compact topological manifolds the proof of the Euclidean Embedding Theorem 27.1 relies on our detailed discussion of the covering dimension of topological manifolds in Chapter 11. For readers who are not familiar with the theory of covering dimensions we outline an alternative proof of the Manifold Metrization Proposition 27.4 (1) in Exercise 27.2.

Example. Let $M = \mathbb{R} \setminus \{0\}$. The usual Euclidean metric on $\mathbb{R}$ shows that M is metrizable, but this metric is of course not complete. The map

$$\begin{array}{rcl} f\colon \mathbb{R} \setminus \{0\} & \to & \mathbb{R}^2 \\ x & \mapsto & (x, \frac{1}{x}) \end{array}$$

is easily seen to be a proper smooth embedding. Thus $\mathbb{R} \setminus \{0\}$ is homeomorphic to a closed subset of $\mathbb{R}^2$. Now the Euclidean metric on $\mathbb{R}^2$ restricts to a *complete* metric on $f(\mathbb{R} \setminus \{0\})$ and thus it gives rise to a complete metric on $\mathbb{R} \setminus \{0\}$.

Proof. For each $n \in \mathbb{N}_0$ we consider the usual Euclidean metric

$$\begin{array}{rcl} e\colon \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ ((x_1,\dots,x_n),(y_1,\dots,y_n)) & \mapsto & \sqrt{\sum_{k=1}^{n} (x_k - y_k)^2}. \end{array}$$

(1) Let M be a topological manifold. By the Euclidean Embedding Theorem 27.1 (1) there exists an $n \in \mathbb{N}$ and a closed embedding $\varphi\colon M \to \mathbb{R}^n$. In other words, M is homeomorphic to the closed subset $\varphi(M) \subset \mathbb{R}^n$. It follows from the elementary Exercise 1.3 that the Euclidean metric e on $\mathbb{R}^n$ restricts to a metric e on $\varphi(M)$ such that the topology coming from e agrees with the topology given by $\varphi(M)$. Finally note that the fact that $\varphi(M)$ is closed in $\mathbb{R}^n$ implies, by the Closed Subspace-Completeness Lemma 6.9, that the metric space $\varphi(M)$ itself is complete.
(2) Let M be a smooth manifold. By the Euclidean Embedding Theorem 27.1 (2) there exists an $n \in \mathbb{N}$ and a closed smooth embedding $\varphi\colon M \to \mathbb{R}^n$. A very elementary argument shows that $e\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ is a smooth map on the open subset set $\{(x,y) \in \mathbb{R}^n \times \mathbb{R}^n \,|\, x \neq y\}$. In (1) we showed that the map $e \circ (\varphi \times \varphi)\colon M \times M \to \mathbb{R}_{\geq 0}$

is a complete metric. Since φ is smooth it follows from the above discussion together with Propositions 19.31 and 20.6 that $e \circ (\varphi \times \varphi)$ is smooth on the open subset $\{(x, y) \in M \times M \,|\, x \neq y\}$. ■

Remark.

(1) In the following chapters we will study several refinements of the Euclidean Embedding Theorem 27.1 for compact smooth manifolds:
   (a) In the Weak Whitney Embedding Theorem 30.7 we will show that any n-dimensional smooth manifold admits a proper smooth embedding into $\mathbb{H}^{2n+1}$.
   (b) In Proposition **??** we will show that any two proper smooth embeddings $M \to \mathbb{H}^n$ are "properly smoothly isotopic" as long as $n > 2\dim(M) + 1$.
   (c) In Proposition **??** we will consider a refinement of Theorem 27.1 for smooth manifolds M that are equipped with a proper submanifold W.

(2) The Euclidean Embedding Theorem 27.1 is not only interesting in its own right, for us the fact that every smooth manifold can be viewed as a proper submanifold of $\mathbb{H}^n$ will come in handy on many occasions. One of the nice consequences of considering submanifolds of $\mathbb{H}^n$ is that it makes it relatively easy to construct many interesting and useful maps. In particular we will use the Euclidean Embedding Theorem 27.1, together with the Neighborhood Projection Theorem 28.1, to prove the following results:
   (a) the Smooth Collar Neighborhood Theorem 28.3,
   (b) the Whitney Approximation Theorem 29.1 and
   (c) the Smooth Manifold-Simplicial Structure Theorem 96.2.

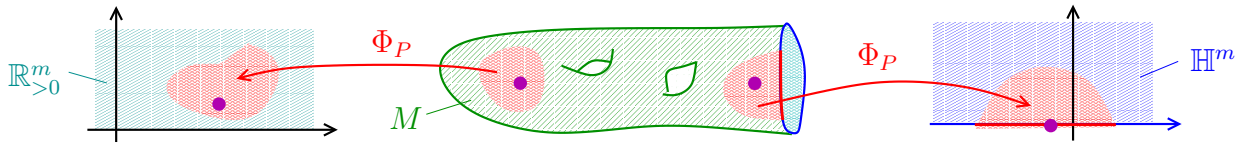
As happens so often in mathematics, the proof of a result immediately invites new questions. For example, in light of the Euclidean Embedding Theorem 27.1 and the Weak Whitney Embedding Theorem 30.7 the following question arises.

Question 27.5. For a given (topological) smooth manifold M, e.g. $M = \mathbb{R}\mathrm{P}^n$, what is the minimal $k \in \mathbb{N}$ such that M admits a (topological) smooth embedding into $\mathbb{R}^k$?

We will give some partial answers for general smooth manifolds in the Weak Whitney Embedding Theorem 30.7 and the Strong Whitney Embedding Theorem **??**. Furthermore we will consider some specific cases of topological and smooth manifolds in Propositions 43.12, 123.11 and the Topological Codimension-One Orientability Proposition 124.5.

27.2. **Proof of the Euclidean Embedding Theorem 27.1 in the compact case.** We start out with the following elementary lemma.

Lemma 27.6. Let M be a compact m-dimensional topological manifold. There exists a finite atlas $\{\Phi_i \colon U_i \to V_i\}_{i=1,\dots,s}$ such that each V_i is an open subset of $\mathbb{H}^m$. If M is a smooth manifold, then we can choose the atlas to be smooth.



Remark. In the next section we will generalize Lemma 27.6 to the non-compact case.

Proof. Let M be a compact m-dimensional topological manifold.

(1) For each $P \in M \setminus \partial M$ we can and will pick a chart $\Phi_P \colon U_P \to V_P$ of type (i) around P with $V_P \subset \mathbb{R}^m_{>0} = \{(x_1, \dots, x_m) \in \mathbb{R}^m \,|\, x_m > 0\} \subset \mathbb{H}^m$.

(2) For each $P \in \partial M$ we pick a chart $\Phi_P \colon U_P \to V_P$ of type (ii) around P, where V_P is an open subset of $\mathbb{H}^m$.

Since the sets $\{U_P\}_{P\in M}$ form an open cover, the desired statement follows immediately from the hypothesis that M is compact. If M is in fact smooth, then we pick charts from the smooth atlas and we are again done. ■

Proof of the Euclidean Embedding Theorem 27.1 in the compact case. In the following we go out of order, we first deal with the slightly more difficult smooth case and then we argue that the topological case follows by essentially the same argument as the smooth case - except for a technical nuisance.

(2) Let M be a compact m-dimensional smooth manifold. By Lemma 27.6 there exists a finite smooth atlas $\{\Phi_i\colon U_i \to V_i\}_{i=1,\dots,s}$ such that each V_i is an open subset of $\mathbb{H}^m$. For $i = 1,\dots,s$ we denote by $\zeta_i\colon U_i \to \mathbb{R}$ the composition of Φ_i with the projection $\mathbb{H}^m \to \mathbb{R}_{\geq 0}$ onto the last coordinate.

By the Manifold-Partitions of Unity Existence Theorem 21.1 we can find a smooth partition of unity $\{\nu_i\colon M \to [0,1]\}_{i=1,\dots,s}$ such that for every $i \in \{1,\dots,s\}$ we have $\operatorname{supp}(\nu_i) \subset U_i$. For $i = 1,\dots,s$ we define

$$\widetilde{\Phi}_i\colon M \to \mathbb{R}^m,\quad x \mapsto \begin{cases} \Phi_i(x)\cdot\nu_i(x), & \text{if } x\in U_i,\\ 0, & \text{else}\end{cases} \qquad \text{and} \qquad \widetilde{\zeta}_i\colon M \to \mathbb{R},\quad x \mapsto \begin{cases} \zeta_i(x)\cdot\nu_i(x), & \text{if } x\in U_i,\\ 0, & \text{else.}\end{cases}$$

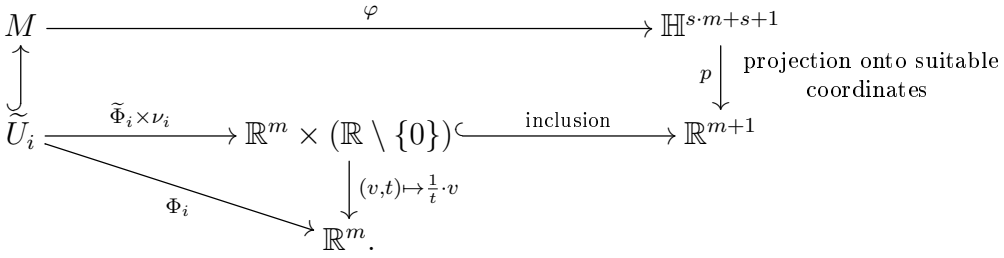
It follows easily from the Smooth Pasting Proposition 19.23 (1) that each of these maps $\widetilde{\Phi}_i$ and $\widetilde{\zeta}_i$ is smooth. It remains to prove the following claim.

Claim. The map

$$\begin{aligned}\varphi\colon M &\to \mathbb{H}^{s\cdot m+s+1}\\ x &\mapsto \Big(\widetilde{\Phi}_1(x),\dots,\widetilde{\Phi}_s(x),\nu_1(x),\dots,\nu_s(x),\sum_{i=1}^{s}\widetilde{\zeta}_i(x)\Big)\end{aligned}$$

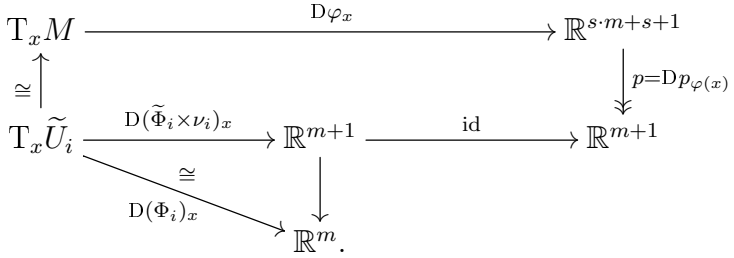
is a proper smooth embedding.

Proof. For completeness' sake we provide the proof of the claim, even though the interest in the full details might be quite muted.



(i) First we show that φ is injective. Thus let $x, x' \in M$ be two distinct points. We pick i with $\nu_i(x) \neq 0$. If $\nu_i(x') \neq \nu_i(x)$, then we are done. Now suppose that $\nu_i(x') = \nu_i(x)$. In particular both are non-zero, thus $x, x' \in U_i$. Since $\Phi_i\colon U_i \to \mathbb{R}^m$ is injective we see that $\Phi_i(x) \neq \Phi_i(x')$. Since $\nu_i(x') = \nu_i(x) \neq 0$ we see that $\widetilde{\Phi}_i(x) \neq \widetilde{\Phi}_i(x')$. This implies that $\varphi(x) \neq \varphi(x')$.

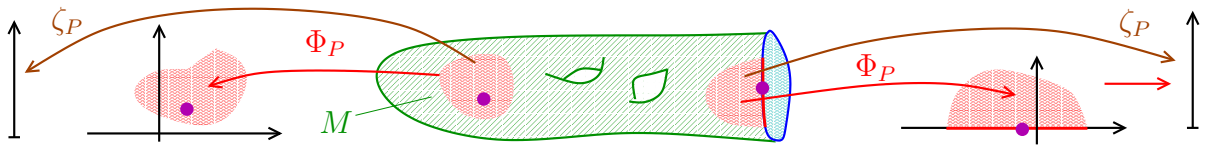
(ii) It follows from (i), the hypothesis that M is compact and the Compact-Hausdorff Proposition 2.17 (2) that the map φ is an embedding.



(iii) We need to show that for each $x \in M$ the differential

$$\mathrm{D}\varphi_x\colon \mathrm{T}_xM \to \mathrm{T}_{\varphi(x)}\mathbb{H}^{s\cdot m+s+1} = \mathbb{R}^{s\cdot m+s+1}$$

is a monomorphism. We pick i with $\nu_i(x) \neq 0$. We consider the open subset $\widetilde{U}_i := \{y \in U_i \,|\, \nu_i(y) \neq 0\}$. Next we consider the following diagram



Here the right vertical map $p\colon \mathbb{H}^{s\cdot m+s+1} \to \mathbb{R}^{m+1}$ is the projection onto the coordinates that correspond to $\widetilde{\Phi}_i$ and ν_i. It is straightforward to see that the diagram commutes. We now now consider the corresponding tangent spaces and differentials:[283]

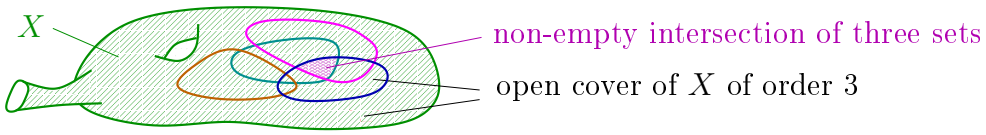
It follows from Lemma 23.12 that the left vertical map, the diagonal map and the right horizontal map are isomorphisms. The combination of these observations now shows that the top horizontal map is a monomorphism.

(iv) Recall that by the Smooth Manifold Boundary Proposition 19.26 (1) a point on the smooth manifold M admits either a smooth chart of type (i) or of type (ii). Furthermore note that it follows easily from our various definitions that the last coordinate of $\varphi(P)$ is zero if and only if $P \in \partial M$. In other words, we have $\varphi^{-1}(\partial\, \mathbb{H}^{s\cdot m+s+1}) = \partial M$.

(v) Using our careful definition of the maps $\widetilde{\zeta}_i$ and using the discussion on page 652 one can verify easily that for every $P \in \partial M$ the image $\mathrm{D}\varphi_P(\mathrm{T}_P M)$ is not contained in $\mathrm{T}_{\varphi(P)}(\partial\, \mathbb{H}^{s\cdot m+s+1})$. ⊞

[283] To preserve sanity we use the convention from page 636, namely given a submanifold Y of some $\mathbb{R}^N$ we do not distinguish between the tangent spaces $\mathrm{T}_y Y$ and $\widetilde{\mathrm{T}}_y Y$.

(1) The proof for compact topological manifolds is basically the same as in (2). There are only two differences:
   (a) In this setting we obtain from the Manifold-Partitions of Unity Existence Theorem 21.1 only a *continuous* partition of unity $\{\nu_i \colon M \to [0,1]\}_{i=1,\dots,s}$. In particular now the map $\varphi \colon M \to \mathbb{H}^{s\cdot m+s+1}$ that we constructed in (a) is an embedding, but evidently we cannot hope for any smoothness properties.
   (b) In the proof of (iv) we used that by the Smooth Manifold Boundary Proposition 19.26 (1) we know that a point on a smooth manifold admits either a smooth chart of type (i) or of type (ii). For the proof that $\varphi^{-1}(\partial\mathbb{H}^{s\cdot m+s+1}) = \partial M$ we need the corresponding statement for topological manifolds which, somewhat awkwardly, we only prove in the Topological Manifold Boundary Proposition 75.2.[284] ■



27.3. **The covering dimension of topological manifolds.** In this section we provide the proof of the Euclidean Embedding Theorem 27.1 in the non-compact case. This case is much more intricate, and thus just so much more fun, than the compact case. The key trick for dealing with the non-compact case is to make use of the concept of the covering dimension of a topological space. For the reader's convenience we recall the definition from page 369.

Definition. Let X be a topological space.
(1) A family $\{U_i\}_{i\in I}$ of subsets of X has order m if the following two statements hold:
   (a) There exists $J \subset I$ with $\#J = m$ such that $\bigcap_{j\in J} U_j \neq \varnothing$.
   (b) For every $J \subset I$ with $\#J > m$ we have $\bigcap_{j\in J} U_j = \varnothing$.

   If no such m exists, then we say that the family has infinite order.
(2) If X is non-empty, then we refer to

$$\operatorname{cdim}(X) \;:=\; \min\left\{ m \in \mathbb{N}_0 \cup \{\infty\} \;\middle|\; \begin{array}{c}\text{every open cover of } X \text{ admits an}\\ \text{open refinement of order} \le m+1\end{array} \right\}$$

as the covering dimension of X. If X is empty, then we set $\operatorname{cdim}(X) := -1$.

Proposition 27.7. (Covering Dimension-of-Manifolds Proposition) For any n-dimensional topological manifold M we have $\operatorname{cdim}(M) \le n$.

Remark.

[284] Note that we also use this statement to conclude that the boundary of the smooth manifold $\mathbb{H}^n$ is indeed $\mathbb{R}^{n-1}\times\{0\}$. If we view $\mathbb{H}^n$ as a topological manifold, then we also need the Topological Manifold Boundary Proposition 75.2 to obtain this result.

(1) Note that as of right now we do not know yet whether a non-empty topological manifold has a uniquely defined dimension. In principle a non-empty topological manifold might have several dimensions. We will verify the uniqueness of dimensions only later in Theorem 77.4 once we have introduced homology groups. But fortunately this issue does not have any impact on the Covering Dimension-of-Manifolds Proposition 27.7.

(2) Once we have introduced homology groups we can also prove Theorem 77.4 which says that the dimension and the covering dimension of a non-empty topological manifold agree.

Proof. Let M be an n-dimensional topological manifold. We start out with the following claim.

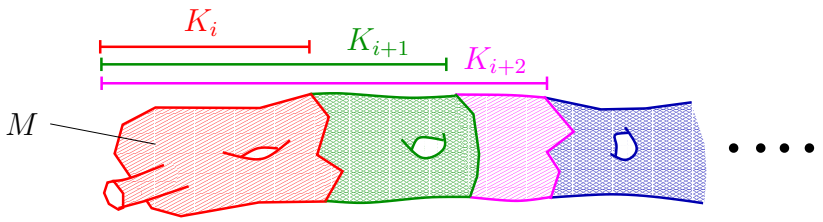
Claim. For every compact subspace $K \subset M$ we have $\operatorname{cdim}(K) \leq n$.

Proof. Since K is compact it follows from a straightforward argument that there exist finitely many charts $\Phi_i \colon U_i \to V_i$, $i = 1, \ldots, k$ and compact subsets $C_i \subset V_i$ such that $K \subset \Phi_1^{-1}(C_1) \cup \cdots \cup \Phi_k^{-1}(C_k)$.

(a) By Theorem 11.3 we know that for each i we have $\operatorname{cdim}(C_i) \leq n$.

(b) By (a) and Lemma 11.1 we know that for each i we have $\operatorname{cdim}(\Phi_i^{-1}(C_i)) \leq n$.

(c) From (b) and the Finite Union-Covering Dimension Proposition 11.6 we obtain that $\operatorname{cdim}(\Phi_1^{-1}(C_1) \cup \cdots \cup \Phi_k^{-1}(C_k)) \leq n$.



(d) Since K is compact and since M is by definition Hausdorff we know by the Compact-Closed Lemma 1.21 that K is a closed subset of $\Phi_1^{-1}(C_1) \cup \cdots \cup \Phi_k^{-1}(C_k)$. Therefore it follows from (c) together with the Closed Subspace Covering Dimension Lemma 11.5 that $\operatorname{cdim}(K) \leq n$. ⊞

We now proceed as in the proof of Corollary 11.9. By the Topological Manifold Exhaustion Lemma 18.12, respectively the Compact Exhaustion Lemma 9.3 (1) we know that there exists a sequence of compact subsets $\{K_i\}_{i \in \mathbb{N}}$ of M such that the following two conditions are satisfied:

(1) for every $i \in \mathbb{N}$ we have $K_i \subset \overset{\circ}{K}_{i+1}$,

(2) we have $M = \bigcup_{i \in \mathbb{N}} K_i$.

Let $i \in \mathbb{N}$. Since $K_{i+1} \setminus \overset{\circ}{K}_i$ is a closed subset of the compact space K_{i+1} we know by the Compact-Closed Lemma 1.21 that $K_{i+1} \setminus \overset{\circ}{K}_i$ is also compact. Therefore, by the above claim, we know that for each i we have $\operatorname{cdim}(K_{i+1} \setminus \overset{\circ}{K}_i) \leq n$. It follows from the Exhaustion-Covering Dimension Proposition 11.8 that $\operatorname{cdim}(M) \leq n$. ■

Remark. For topological manifolds without boundary we now have an off-the-shelves proof of the Euclidean Embedding Theorem 27.1. Indeed, let X be an n-dimensional topological manifold. In the Covering Dimension-of-Manifolds Proposition 27.7 we just showed that $\operatorname{cdim}(X) \leq n$. By definition X is Hausdorff and second-countable. Furthermore, by the Topological Manifolds-Local Properties Lemma 18.8 we know that X is regionally compact. Thus it follows from the Euclidean Embedding Theorem 11.13 for Topological Spaces that there exists a closed embedding $X \to \mathbb{R}^{2n+1}$. Note though that this embedding does not give us any control over ∂X. Also this approach does not give us anything meaningful for smooth manifolds.

27.4. **Proof of the Euclidean Embedding Theorem 27.1 in the non-compact case.** We can now generalize Lemma 27.6 to the non-compact case. Since the proof is no longer trivial we upgrade the statement from a lemma to a proposition. This proposition might well be interesting in its own right.

Proposition 27.8. (Small Atlas Proposition) Let $m \geq 2$ and let M be an m-dimensional topological manifold.[285]

(1) There exists an atlas $\{\Phi_i \colon U_i \to V_i\}_{i \in I}$ consisting of at most $m+1$ charts, such that each V_i is an open subset of $\mathbb{H}^m$.
(2) If M is a smooth manifold, then we can choose the atlas to be smooth.

Remark. Given an n-dimensional smooth manifold M we define, following [**Bers1968, Hopk1989**] the

$$\text{embedding covering number } N(M) \ := \ \begin{array}{c}\text{minimal cardinality of an open cover } \{U_i\}_{i \in I} \\ \text{of } M \text{ such that each } U_i \text{ admits a} \\ \text{smooth embedding into } \mathbb{R}^n.\end{array}$$

Note that the embedding covering number is precisely the minimal cardinality of a smooth atlas of M. By the Small Atlas Proposition 27.8 we know that $N(M) \leq \dim(M) + 1$. Evidently $N(M) \leq 1$ if and only if M is diffeomorphic to an open subset of some $\mathbb{R}^n$. It follows from this observation that for a non-empty closed smooth manifold we have $N(M) \geq 2$. We deduce from Proposition 19.18 that $N(S^n) = 2$. In general it is very difficult to determine $N(M)$ for a given smooth manifold M. For example let us consider the real projective space $\mathbb{R}\mathrm{P}^n$. We write $n+1 = 2^k \cdot m$ with m odd. If $n \neq 31$ and $n \neq 47$, then it is shown in [**Hopk1989**, Theorem 1] (see also [**Bers1968**, Theorem 1.5]) that

$$N(\mathbb{R}\mathrm{P}^n) \ = \ \begin{cases} \max\{2, m\}, & \text{if } k \leq 3, \\ \lceil \frac{n+1}{2(k+1)} \rceil, & \text{if } k \geq 4. \end{cases}$$

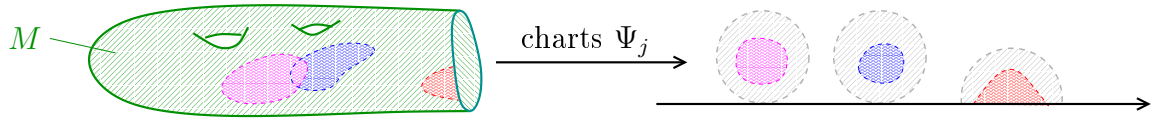
This result is surely not what was on everybody's lips. Later on we will prove a related result, namely we will show in Proposition 121.18 that any open cover of $\mathbb{R}\mathrm{P}^n$ by contractible open subsets (e.g. by open subsets that are diffeomorphic to $\mathbb{R}^n$) has cardinality at least $n+1$.

[285] Note that the condition $m \geq 2$ is indeed necessary, namely the conclusion does *not* hold for the 1-dimensional smooth manifold $M = [0,1] \sqcup [0,1]$.

Proof. In the following we only deal with the case of a smooth manifold. It is straightforward to modify the argument to deal with topological manifolds.

Let M be an m-dimensional smooth manifold. Similar to the compact case we make the following preparations:

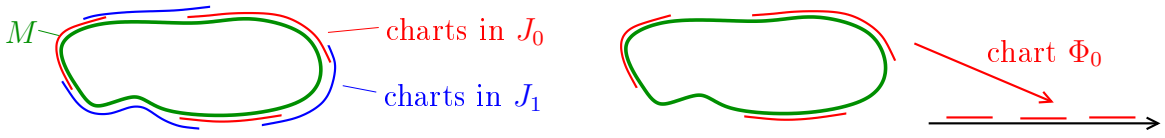
(a) For each $P \in M \setminus \partial M$ we pick a smooth chart $\Phi_P \colon U_P \to B^m((0,\dots,0,1))$ of type (i) around P.



(b) For each $P \in \partial M$ we pick a smooth chart $\Phi_P \colon U_P \to B^m(0) \cap \mathbb{H}^m$ of type (ii) around P.

Note that $\{U_P\}_{P\in M}$ is an open cover of M. In the Covering Dimension-of-Manifolds Proposition 27.7 we just showed that $\operatorname{cdim}(M) \leq m$. By the Manifold Paracompact-Normal Proposition 18.9 (1) we know that M is paracompact and by definition we know that M is second-countable. Thus it follows from the Covering Dimension Refinement Theorem 11.12 that there exists a locally finite open refinement $\{V_j\}_{j\in J}$ of the open cover $\{U_P\}_{P\in M}$ and countable subsets $J_0,\dots,J_m$ of J with $J = J_0 \sqcup \dots \sqcup J_m$ such that for any $n \in \{0,\dots,m\}$ and any $r,s \in J_n$ we have $V_r \cap V_s = \varnothing$.

Since $\{V_j\}_{j\in J}$ is a refinement of $\{U_P\}_{P\in M}$ we can pick for each $j \in J$ a $P_j \in M$ with $V_j \subset U_{P_j}$. Note that the images of the charts Φ_{P_j} have diameter 2. Thus, since J is countable and since $m \geq 2$ we can find a family of points $\{Q_j\}_{j\in J}$ in $\mathbb{R}^{m-1}$ such the images of the maps

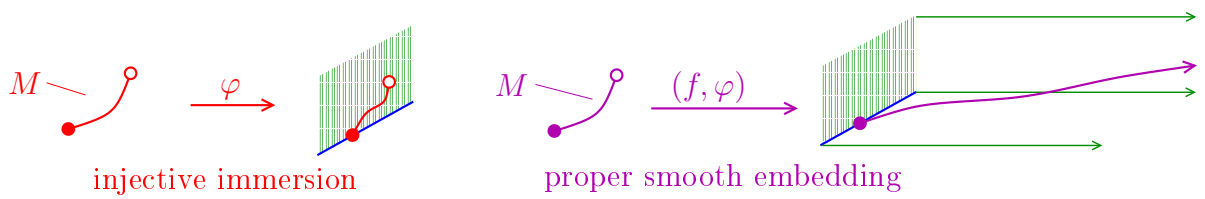


$$\begin{array}{rcl} \Psi_j \colon V_j & \to & \mathbb{R}^m \\ x & \mapsto & \Phi_{P_j}(x) + (Q_j, 0) \end{array}$$

are disjoint. Finally for $i \in \{1,\dots,m+1\}$ we now consider the map

$$\Phi_i := \bigsqcup_{j\in J_i} \Psi_j \colon V_j \to \mathbb{R}^m.$$

Note that, basically by construction, Φ_i is a chart and these charts $\Phi_1,\dots,\Phi_{m+1}$ form a smooth atlas for M. ∎



Our proof of the Euclidean Embedding Theorem 27.1 in the non-compact case also rests on the following lemma.

Lemma 27.9. Let M be a smooth manifold, let $\varphi \colon M \to \mathbb{H}^d$ be an injective immersion and let $f \colon M \to \mathbb{R}_{\geq 0}$ be a smooth exhaustion function, i.e. $f \colon M \to [0,\infty)$ is a smooth map such that the preimage of every compact interval is compact.[286] Then the map

$$\begin{array}{rcl} (f,\varphi) \colon M & \to & \mathbb{R} \times \mathbb{H}^d = \mathbb{H}^{d+1} \\ x & \mapsto & (f(x), \varphi(x)) \end{array}$$

is a proper smooth embedding. The same statement holds if we replace $\mathbb{H}^d$ by any other smooth manifold.

Proof of Lemma 27.9. It is clear that the map $(f,\varphi)\colon M \to \mathbb{R}\times\mathbb{H}^d$ is still an injective immersion with $\partial M = (f,\varphi)^{-1}(\partial\mathbb{H}^{d+1})$. Furthermore it follows easily from the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19, or alternatively from the Proper-Closed Proposition 2.43, that the map $(f,\varphi)\colon M \to \mathbb{R}\times\mathbb{H}^d$ is a closed embedding. These two observations show that the map $(f,\varphi)\colon M \to \mathbb{R}\times\mathbb{H}^d$ is a proper smooth embedding. ■

Proof of the Euclidean Embedding Theorem 27.1 in the non-compact case. In the following we deal with the smooth case. The case of topological manifolds is dealt with in a very similar fashion.

Let M be a (possibly non-compact) m-dimensional smooth manifold. If $m = 0$, then it follows easily from the fact that M is second-countable that we can find a smooth embedding $M \to \mathbb{R}$. If $m = 1$, then the statement can be proved easily "by hand" using the Topological 1-Dimensional Manifold Classification Theorem 22.1 and using the fact that a smooth manifold, by virtue of being second-countable, has countably many components.

So now assume that $m \geq 2$. In the proof of the Euclidean Embedding Theorem 27.1 for compact manifolds we used the compactness so that we could appeal to Lemma 27.6. Now, that M is possibly non-compact, we appeal to the Small Atlas Proposition 27.8, and we obtain a smooth atlas $\{\Phi_i\colon U_i \to V_i\}_{i=1,\dots,m+1}$ such that each V_i is an open subset of $\mathbb{H}^m$. We apply the argument in the proof of the Euclidean Embedding Theorem 27.1 on page 723 and we see that there exists a $d \in \mathbb{N}$ and an injective immersion

$$\varphi\colon M \to \mathbb{H}^d$$

with $\partial M = \varphi^{-1}(\partial\mathbb{H}^d)$. If M is compact, then it follows from the Compact-Hausdorff Proposition 2.17 (2) that the map φ is an embedding.

If M is non-compact we have to put in some extra effort. First note that by the Manifold Exhaustion Lemma 21.2 we know that M admits a smooth exhaustion function, i.e. there exists a smooth map $f\colon M \to [0,\infty)$ such that the preimage of every compact interval is compact. By Lemma 27.9 we know that the map

$$\begin{array}{rcl}(f,\varphi)\colon M & \to & \mathbb{R}\times\mathbb{H}^d = \mathbb{H}^{d+1}\\ x & \mapsto & (f(x),\varphi(x))\end{array}$$

is a proper smooth embedding. ■

Exercises for Chapter 27.

[286]Note that by the Manifold Exhaustion Lemma 21.2 we know that every smooth manifold M admits a smooth exhaustion function.

Exercise 27.1. Recall that on page 627 we introduced the category $\mathcal{PSmMfd}$ of pointed smooth manifolds and we introduced the category $\mathcal{PSmMfd}_{\mathbb{R}^n}$ of pointed smooth submanifolds of some $\mathbb{R}^n$. In Question 23.6 (2) we asked whether the covariant functor

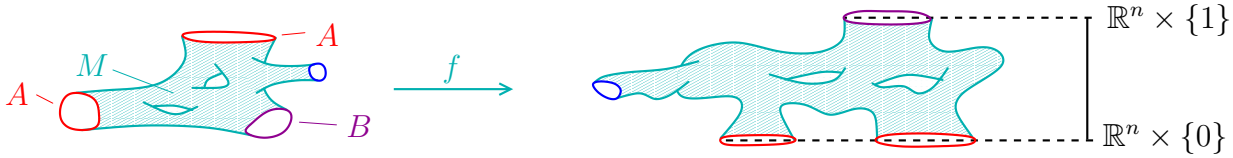
$$\begin{array}{rcl} \mathcal{PSmMfd}_{\mathbb{R}^n} & \to & \mathcal{Vec}_{\mathbb{R}} \\ (M,P) & \mapsto & \widetilde{\mathrm{T}}_P M \end{array}$$

can be extended in an "essentially unique" way to the category $\mathcal{PSmMfd}$. In the Tangent Space-Isomorphism Proposition 23.16 (4) we showed that such an extension exists. Turn the "essentially unique" into a precise statement and answer the question in the affirmative. *Hint.* Use the Euclidean Embedding Theorem 27.1 and reread Section 3.4.

Exercise 27.2. We consider

$$\ell^2(\mathbb{N}) \;:=\; \Big\{(x_1,x_2,\dots)\in\mathbb{R}^{\mathbb{N}} \;\Big|\; \sum_{i=1}^{\infty} x_i^2 < \infty\Big\}.$$

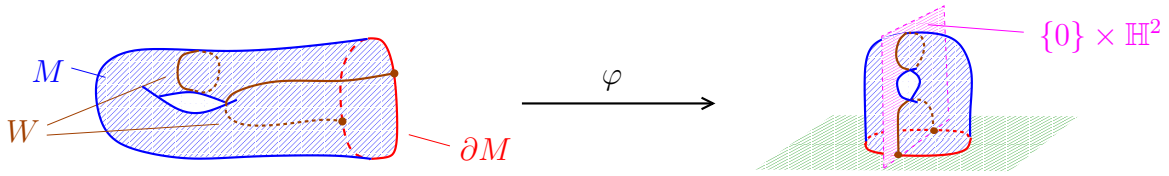
(a) We consider the map



$$\begin{array}{rcl} d\colon \ell^2(\mathbb{N})\times\ell^2(\mathbb{N}) & \to & \mathbb{R}_{\geq 0} \\ ((x_1,x_2,\dots),(y_1,y_2,\dots)) & \mapsto & \sqrt{\sum_{i=1}^{\infty}(x_i-y_i)^2}. \end{array}$$

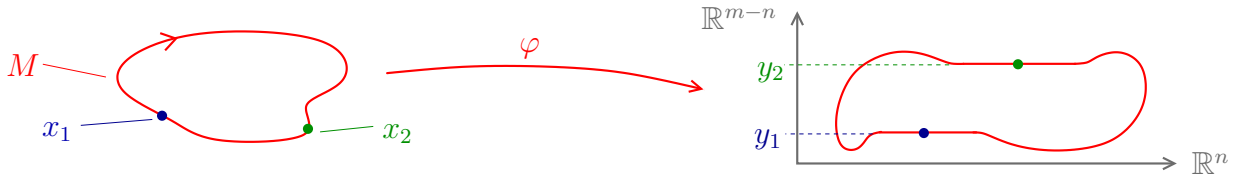
Show that this map does indeed take finite values and show that it defines a complete metric on $\ell^2(\mathbb{N})$.

(b) Let M be a topological manifold. Modify the argument of Section 27.2 to show that there exists a closed embedding $\varphi\colon M\to\ell^2(\mathbb{N})$.



Remark. This exercise, together with the Closed Subspace-Completeness Lemma 6.9, provides a new proof that (possibly non-compact) topological manifolds are completely metrizable. In other words, it provides a proof of the Manifold Metrization Proposition 27.4 (1) that does not make use of the concept of covering dimension that we had developed in Chapter 11.

Exercise 27.3. Let M be a compact smooth manifold and let A and B be disjoint unions of components of ∂M such that $\partial M = A\sqcup B$. Show that there exists a proper smooth embedding $f\colon M\to\mathbb{R}^n\times[0,1]$ such that $A = f^{-1}(\mathbb{R}^n\times\{0\})$ and $B = f^{-1}(\mathbb{R}^n\times\{1\})$.



Exercise 27.4. Let M be a smooth manifold without boundary. Show that there is no metric $d\colon M\times M\to\mathbb{R}_{\geq 0}$ which is a smooth map from the smooth manifold $M\times M$ to the smooth manifold $\mathbb{R}_{\geq 0}$.

Exercise 27.5. Let M be a compact m-dimensional smooth manifold and let W be a (possibly empty) proper submanifold of M. Show that there exists a proper smooth embedding $\varphi\colon M\to\mathbb{H}^n$ and a $k\in\{0,\dots,n-1\}$ such that $\varphi(W) = \varphi(M)\cap(\{0\}\times\mathbb{H}^k)$.

Exercise 27.6. Let M be a closed n-dimensional smooth manifold and let $x_1, \dots, x_k \in M$ be disjoint points. Show that there exists a smooth embedding $\varphi\colon M \to \mathbb{R}^m$ such that $\varphi(M)$ is "flat" near $\varphi(x_1), \dots, \varphi(x_k)$, in the sense that there exist disjoint neighborhoods $U_1, \dots, U_k$ of $x_1, \dots, x_k$ and points $y_1, \dots, y_k \in \mathbb{R}^{m-n}$ such that for each $i \in \{1, \dots, k\}$ we have $\varphi(U_i) \subset \mathbb{R}^n \times \{y_i\}$.

Exercise 27.7. Let M be the smooth manifold that is obtained from the open disk B^2 by removing the three points $(0, -\frac{1}{2}), (0, 0)$ and $(0, \frac{1}{2})$. Give an explicit proper smooth embedding $f\colon M \to \mathbb{R}^3$.

Remark. This exercise is the "smooth version" of Exercise 11.13. In Exercise 43.12 we will see that there is no proper smooth embedding $f\colon M \to \mathbb{R}^2$.

Exercise 27.8. Given an n-dimensional smooth manifold M we define, following [**Bers1968, Hopk1989**] the

$$\text{embedding covering number } N(M) := \begin{array}{c}\text{minimal cardinality of an open cover } \{U_i\}_{i\in I} \\ \text{of } M \text{ such that each } U_i \text{ admits a} \\ \text{smooth embedding into } \mathbb{R}^n.\end{array}$$

In other words, the embedding covering number is precisely the minimal cardinality of a smooth atlas of M.

(a) Given $g \in \mathbb{N}$, what is the embedding covering number of the surface of genus g?
(b) Show that $N(\mathbb{R}\mathrm{P}^2) = 3$.
(c) What is the embedding covering number of the Klein bottle?

Remark. With the present knowledge one can give upper bounds to $N(M)$ but it is difficult to give very meaningful lower bounds on $N(M)$. So the task is to give the best possible upper bounds.

28. The Neighborhood Projection Theorem and Smooth Collar Neighborhoods

As the title of the chapter strongly suggests, in this chapter we will state, prove and discuss the Neighborhood Projection Theorem 28.1 and the Smooth Collar Neighborhood Theorem 28.3. Both are essential tools in the study of smooth manifolds and will be used frequently.

28.1. The Neighborhood Projection Theorem.

In this section we state the Neighborhood Projection Theorem, which is a key tool in many of our future constructions. To state the theorem it is necessary to introduce the following definition.

Definition. A map $f\colon M \to N$ between smooth manifolds is called a submersion if f is smooth and if given any $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is an epimorphism.

With this definition in our bag we can state the Neighborhood Projection Theorem.

Theorem 28.1. (Neighborhood Projection Theorem) Let M be a proper k-dimensional smooth submanifold of $\mathbb{R}^n$ with $\partial M = \varnothing$.[287] Given $P \in M$ we write

$$\big(\widetilde{\mathrm{T}}_P M\big)^{\perp} \;=\; \{w \in \mathbb{R}^n \,|\, \langle v, w\rangle = 0 \text{ for all } v \in \widetilde{\mathrm{T}}_P M\}.$$

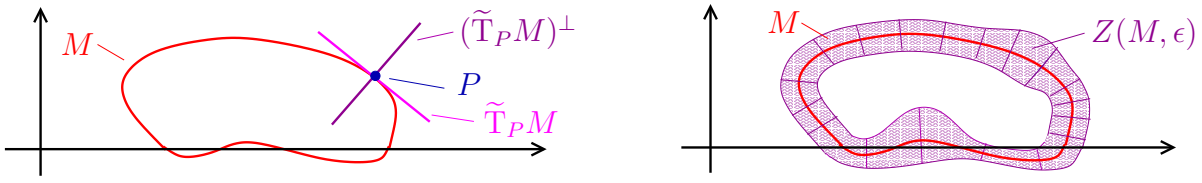
There exists a smooth map $\epsilon\colon M \to (0,\infty)$ such that the following conditions are satisfied:

(1) The subset

$$Z(M,\epsilon) \;:=\; \big\{P + w \,|\, P \in M \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^{\perp} \text{ with } \|w\| < \epsilon(P)\big\} \;\subset\; \mathbb{R}^n$$

is an open neighborhood of $M \subset \mathbb{R}^n$.

(2) The map



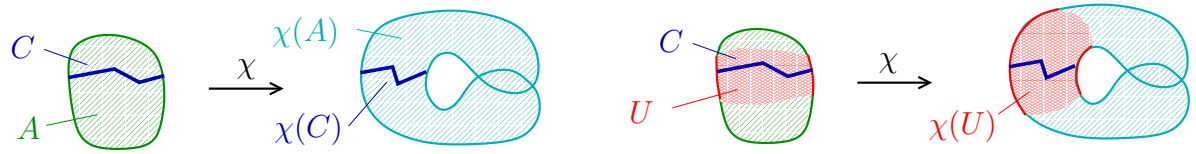
$$\begin{array}{rcll} \pi\colon Z(M,\epsilon) & \to & M & \\ P + w & \mapsto & P & \text{where } P \in M \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^{\perp} \text{ with } \|w\| < \epsilon(P) \end{array}$$

is well-defined, it is smooth, it is a submersion, and it is a retraction $Z(M,\epsilon) \to M$. Furthermore there exists a smooth[288] deformation retraction

$$R\colon Z(M,\epsilon) \times [0,1] \;\to\; Z(M,\epsilon)$$

with $R_0 = \mathrm{id}$ and with $R_1 = \pi\colon Z(M,\epsilon) \to M$.

If M is compact, then we can choose ϵ to be a constant map.



[287] Since $\partial M = \varnothing$ we see, by the definition on page 550, that in our context "proper" just means that M is a closed subset of $\mathbb{R}^n$.

[288] Note that $Z(M,\epsilon)$ is a smooth manifold with empty boundary. Thus by the Smooth Manifold Product Proposition 19.31 we know that $Z(M,\epsilon) \times [0,1]$ is a smooth manifold. So it makes sense for a map $Z(M,\epsilon) \times [0,1] \to Z(M,\epsilon)$ to be smooth.

Remark. In Borsuk's Theorem 104.3 we will prove a variation of the Neighborhood Projection Theorem 28.1 that also holds for closed subspaces of $\mathbb{R}^n$ that are topological manifolds.

Before we can provide the proof of the Neighborhood Projection Theorem 28.1 we need to make a few preparations. First, for the reader's convenience we recall the following theorem which will play a role on three occasions in this chapter.

Theorem 21.13. (Neighborhood Smooth Embedding Theorem) Let $\chi\colon A \to B$ be a map between smooth manifolds. Furthermore let $C \subset A$ be a closed subset such that the map $\chi\colon C \to \chi(C)$ is a homeomorphism and such that $\chi(C)$ is a closed subset of B. If χ is a local diffeomorphism at each $P \in C$, then there exists an open neighborhood U of C such that the restriction of χ to U is a smooth embedding and such that $\chi(U)$ is an open subset of B.

Our proof of the Neighborhood Projection Theorem 28.1 relies on a lemma that will also come in handy when we prove the Smooth Collar Neighborhood Theorem 28.3. Therefore we formulate the lemma in a more general fashion than is strictly needed for just the proof of the Neighborhood Projection Theorem 28.1.

Lemma 28.2. (Normal Vectors Lemma) Let M be a proper k-dimensional smooth submanifold of $\mathbb{H}^n$. We set

$$WM := \big\{(P,w) \in \mathbb{H}^n \times \mathbb{R}^n \,|\, P \in M \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^\perp\big\}.$$

The following three statements hold:

(1) The subset WM is an n-dimensional submanifold of $\mathbb{H}^n \times \mathbb{R}^n$ where the boundary is given by $\partial(WM) = WM \cap (\partial\mathbb{H}^n \times \mathbb{R}^n)$.

(2) Given any point $P \in M$ and given any open neighborhood U of $P \in WM$ there exists an open neighborhood U_P of $P \in M$ and an $\epsilon_P > 0$ such that the subset $\big\{(x,w) \in \mathbb{H}^n \times \mathbb{R}^n \,|\, x \in U_P \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^\perp \text{ with } \|w\| < \epsilon_P\big\}$ is contained in U.

(3) The map

$$\begin{aligned} \Pi\colon WM &\to M \\ (P,w) &\mapsto P \end{aligned}$$

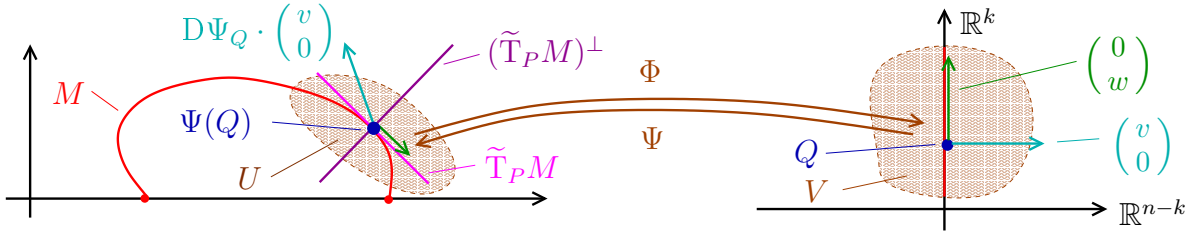
is a submersion.

An analogous statement also holds if we replace $\mathbb{H}^n$ by $\mathbb{R}^n$.

Proof of the Normal Vectors Lemma 28.2. In the following we deal with the case that M is a proper k-dimensional smooth submanifold of $\mathbb{H}^n$. The case $\mathbb{R}^n$ is dealt with in almost the same way. Let $\Phi\colon U \to V$ be a submanifold chart of $M \subset \mathbb{H}^n$. We write $\Psi := \Phi^{-1}\colon V \to U$.

Note that $W(V \cap \Phi(M))$ is given by setting some coordinates of $V \times \mathbb{R}^n \subset \mathbb{H}^n \times \mathbb{R}^n$ to zero. Unfortunately the map $\Psi = \Phi^{-1}\colon V \to U$ does not quite induce a map $W(V \cap \Phi(M)) \to W(U \cap M) \subset WM$ since it does not preserve orthogonality. But this problem can be fixed by introducing a map that "makes vectors orthogonal".

We introduce the following map:[289]



$$\begin{aligned}\Theta\colon (\mathbb{R}^n \setminus \{0\})^k \times \mathbb{R}^n &\to \mathbb{R}^n \\ (v_1, \dots, v_k, w) &\mapsto \underbrace{w - \sum_{i=1}^{k} \langle w, v_i\rangle \cdot \frac{v_i}{\|v_i\|^2}}_{\text{orthogonal to } v_1,\dots,v_k}\end{aligned}$$

Next we consider the map

$$\begin{aligned}G_\Psi\colon V \times \mathbb{R}^{n-k} \times \mathbb{R}^k &\to U \times \mathbb{R}^n \\ (Q, v, w) &\mapsto \Big(\Psi(Q), \underbrace{\Theta\big(\underbrace{\mathrm{D}\Psi_Q(e_{n-k+1}), \dots, \mathrm{D}\Psi_Q(e_n)}_{\text{basis of } \widetilde{\mathrm{T}}_{\psi(Q)}M}, \mathrm{D}\Psi_Q \cdot \begin{pmatrix} v \\ 0 \end{pmatrix}, \mathrm{D}\Psi_Q \cdot \begin{pmatrix} 0 \\ w \end{pmatrix}\big)}_{\in (\widetilde{\mathrm{T}}_{\psi(Q)}M)^\perp}\Big).\end{aligned}$$

One can easily show that the map G_Ψ is a bijection and smooth. Furthermore using the Smooth Pasting Proposition 19.23 (2) one can show fairly easily that G_Ψ is in fact a diffeomorphism. Furthermore, once one has digested the definitions it is also quite clear that the $G_\Psi^{-1}\colon U \times \mathbb{R}^n \to V \times \mathbb{R}^n$ defines (after a suitable permutation of the coordinates) a submanifold chart for WM. All the charts G_Ψ^{-1} show that WM is an n-dimensional submanifold of $\mathbb{H}^n \times \mathbb{R}^n$.

Furthermore note that it follows from the fact that M is a proper submanifold of $\mathbb{H}^n$ and the fact that the submanifold charts Ψ and G_Ψ have the same type, in the sense of the definition on page 550, that $\partial(WM) = WM \cap (\partial\mathbb{H}^n \times \mathbb{R}^n)$. In other words, we have completed the proof of Statement (1).

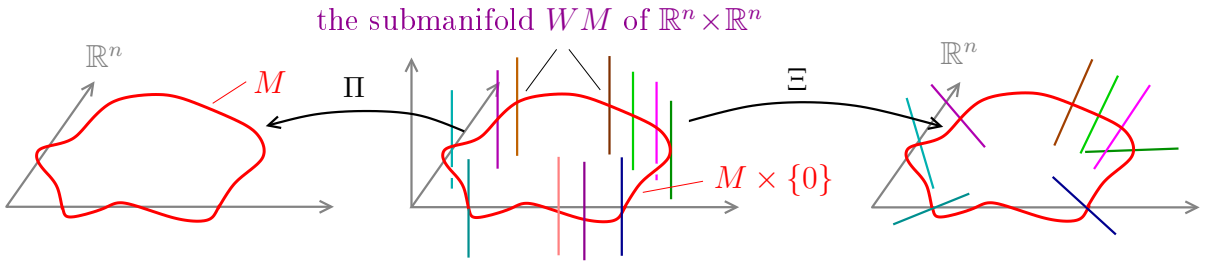
Next note that Statement (2) is a straightforward consequence of the definition of the product topology on $\mathbb{H}^n \times \mathbb{R}^n$ and the definition of the subspace topology on $WM \subset \mathbb{H}^n \times \mathbb{R}^n$.

Finally we turn to the proof of Statement (3). We need to show that $\Pi\colon WM \to M$ is a submersion. Given $(P, v) \in WM$ we pick a submanifold chart $\Phi\colon U \to V$ for $P \in M$ as above. We make use of the above notation and we obtain the following diagram

$$\begin{array}{ccc} (V \cap (\{0\} \times \mathbb{R}^k)) \times \mathbb{R}^{n-k} \times \{0\} & \xrightarrow[\cong]{G_\Psi} & W(U \cap M) \\ \downarrow{\scriptstyle (x,v)\mapsto x} & & \downarrow{\scriptstyle \Pi} \\ V \cap (\{0\} \times \mathbb{R}^k) & \xrightarrow[\cong]{\Psi} & U \cap M. \end{array}$$

It follows easily from the earlier discussion that the horizontal maps are diffeomorphisms and that the diagram commutes. Evidently the map to the left is a submersion, thus the

[289] Here $\langle -, - \rangle\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ denotes the usual Euclidean bilinear symmetric form on $\mathbb{R}^n$.



map to the right is also a submersion. This shows that Π is locally a submersion, but this implies evidently that Π is also a submersion as a whole. ■

Proof of the Neighborhood Projection Theorem 28.1. Let M be a proper k-dimensional smooth submanifold of $\mathbb{R}^n$. As in the Normal Vectors Lemma 28.2 we consider again

$$WM := \big\{(P,w) \in \mathbb{R}^n \times \mathbb{R}^n \,|\, P \in M \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^\perp\big\}.$$

By the Normal Vectors Lemma 28.2 we know that WM is an n-dimensional submanifold of $\mathbb{R}^n \times \mathbb{R}^n$. We consider the maps

$$\begin{array}{rcl} \Pi\colon WM & \to & M \\ (P,w) & \mapsto & P \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \Xi\colon WM & \to & \mathbb{R}^n \\ (P,w) & \mapsto & P+w. \end{array}$$

We make the following observations:

(a) The map $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ that is given by $(P,w) \to P+w$ is evidently smooth. Since WM is a smooth submanifold we obtain from Lemmas 19.22 and 19.24 that the map $\Xi\colon WM \to \mathbb{R}^n$ is smooth.

(b) Let $P \in M$. It follows easily from $\widetilde{\mathrm{T}}_P M \oplus (\widetilde{\mathrm{T}}_P M)^\perp = \mathbb{R}^n$, together with the discussion of the differential of a linear map on page 536 and the fact that WM is an n-dimensional smooth manifold that the differential of $\Xi\colon WM \to \mathbb{R}^n$ at $(P,0) \in WM$ is an isomorphism.

(c) It follows almost immediately from (b), our hypothesis that $\partial M = \varnothing$, the Local Smooth Embedding Theorem 24.8 and the Normal Vectors Lemma 28.2 (2) that for each point $P \in M$ there exists an open neighborhood W_P of $(P,0) \in WM$ such that the restriction of $\Xi\colon WM \to \mathbb{R}^n$ to W_P is a smooth embedding.

(d) Note that the restriction of $\Xi\colon WM \to M$ to $M \times \{0\}$ is given by $(P,0) \mapsto P$. This is evidently an embedding. By hypothesis M is a proper smooth submanifold of $\mathbb{R}^n$ which means in particular, by definition of "proper", that $M = \Xi(M \times \{0\})$ is a closed subset of $\mathbb{R}^n$.

(e) It follows from (b), (c) and (d), together with the Neighborhood Smooth Embedding Theorem 21.13, that there exists an open neighborhood U of $M \times \{0\} \subset WM$ such that the restriction of Ξ to $\Xi|_U\colon U \to \mathbb{R}^n$ is a smooth embedding and such that $\Xi(U)$ is an open subset of $\mathbb{R}^n$.

(f) It follows from the Replace-by-Smooth Non-Negative Function Corollary 21.11 (2) together with the Normal Vectors Lemma 28.2 (2) that there exists a smooth map $\epsilon\colon M \to (0,\infty)$ such that for each $x \in M$ and each $w \in \big(\widetilde{\mathrm{T}}_x M\big)^\perp$ with $\|w\| < \epsilon(x)$ we have $(x,w) \in U$.

We set

$$W(\epsilon) \;:=\; \big\{(P,w) \in WM \,|\, P \in M \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^\perp \text{ with } \|w\| < \epsilon(P)\big\} \;\subset\; WM.$$

The theorem is now a consequence of the following observations:

(i) It follows easily from the definition of the subspace topology that $W(\epsilon)$ is an open subset of WM.

(ii) It follows from (i) together with (e) and (f) that the restriction of $\Xi\colon WM \to \mathbb{R}^n$ to $\Xi\colon W(\epsilon) \to \mathbb{R}^n$ is a smooth embedding such that the image is open.

(iii) The image of $\Xi\colon W(\epsilon) \to \mathbb{R}^n$ is precisely $Z(M,\epsilon)$.

(iv) The map

$$\begin{array}{rcll} \pi\colon Z(M,\epsilon) & \to & M & \\ P+w & \mapsto & P & \text{where } P \in M \text{ and } w \in \big(\widetilde{\mathrm{T}}_P M\big)^\perp \text{ with } \|w\| < \epsilon(P) \end{array}$$

is precisely the map $\Pi \circ \Xi^{-1}\colon Z(M,\epsilon) \to M$ and thus well-defined.

(v) It follows from the Smooth Embedding Theorem 24.10 that $\Xi\colon U \to \Xi(U)$ is a diffeomorphism. Furthermore we know by the Normal Vectors Lemma 28.2 that $\Pi\colon WM \to M$ is a submersion. It follows that $\pi = \Pi \circ \Xi^{-1}\colon \Xi(U) \to M$ is a submersion.

(vi) There exists an obvious smooth deformation retraction from $W(\epsilon)$ to $M \times \{0\}$. Under the diffeomorphism Ξ is gives rise to the desired smooth deformation retraction $R\colon Z(M,\epsilon) \times [0,1] \to Z(M,\epsilon)$ with $R_0 = \mathrm{id}$ and $R_1 = \pi\colon Z(M,\epsilon) \to M$.

For the reader's and the author's convenience we summarize the various maps in the following commutative diagram:

$$\begin{array}{ccccc} WM & \hookleftarrow & U & \hookleftarrow & W(\epsilon) \\ \downarrow \Xi & & \cong \downarrow \Xi & & \cong \downarrow \Xi \\ \mathbb{R}^n & \hookleftarrow & \Xi(U) & \hookleftarrow & Z(M,\epsilon) \end{array} \qquad \begin{array}{c} \overset{\Pi}{\searrow} \\ \underset{\pi}{\rightleftarrows} \end{array} \; M.$$

Finally if M is compact, then it follows from the Compact Image Lemma 2.13 that the map $\epsilon\colon M \to \mathbb{R}_{>0}$ assumes a minimal value > 0. Thus we can replace ϵ throughout by this minimal value > 0. ∎

28.2. **Statement of the Smooth Collar Neighborhood Theorem.** In this section we will state the Smooth Collar Neighborhood Theorem which is another important tool in differential topology.

Definition. Let M be a smooth manifold. A collar of ∂M is defined as a smooth embedding $\chi\colon [0,1] \times \partial M \to M$ that has the following two properties:

(a) the restriction of χ to $\{0\} \times \partial M$ is the obvious map $(0,P) \mapsto P$,

(b) the image $\chi([0,1] \times \partial M)$ is a closed subset of M.

We refer to the image of χ as a collar neighborhood.

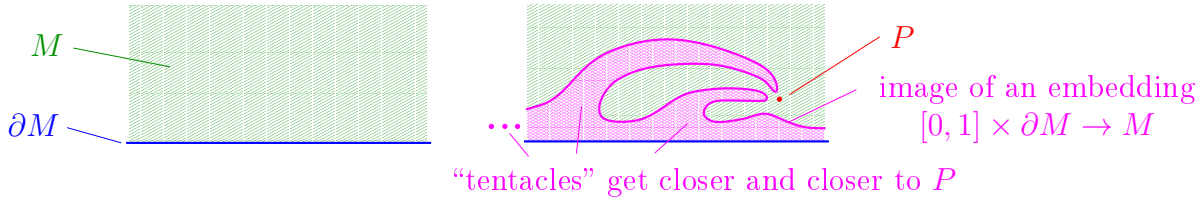
Example. Let $m \in \mathbb{N}$ and let W be a smooth manifold with $\partial W = \varnothing$. The map

$$\begin{array}{rcl} \chi\colon [0,1] \times (S^{m-1} \times W) & \to & \overline{B}^m \times W \\ (t,P,w) & \mapsto & ((1-\frac{1}{2}t)\cdot P, w) \end{array}$$

is evidently a collar for the smooth manifold $\overline{B}^m \times W$. We refer to this map as the standard collar of $\overline{B}^m \times W$ and we refer to the image of f as the standard collar neighborhood of $\overline{B}^m \times W$.

standard collar neighborhood for $\partial M = S^1$ collar neighborhood for ∂M

Convention.



(1) We continue with the notation from the definition. By abuse of notation we sometimes denote the image of a collar $\chi\colon [0,1] \times \partial M \to M$ by $[0,1] \times \partial M$ as well. In particular sometimes we make the identification $\{0\} \times \partial M = \partial M$.
(2) Let $m \in \mathbb{N}$ and let W be a smooth manifold with $\partial W = \varnothing$. Unless we say something else we will equip $\overline{B}^m \times W$ with the above standard collar.

Warning. Suppose that the smooth manifold M is oriented. On page 689 we equipped ∂M with a natural orientation. As usual the smooth manifold $[0,1]$ comes with its standard orientation. Let us now equip $[0,1] \times \partial M$ with the product orientation that we introduced on page 695. It follows from the Product Orientation Proposition 25.22 (4d) that, as an oriented smooth manifold, $\partial([0,1] \times \partial M) = \partial([0,1]) \times M = -(\{0\} \times \partial M) \cup (\{1\} \times \partial M)$. Thus we see that every collar $[0,1] \times \partial M \to M$ is *orientation-reversing*. In principle it would thus be better to define a collar as a smooth embedding $[-1,0] \times \partial M \to M$ which is the "identity" on $\{0\} \times M$. But such a choice would be notationally awkward at times. So we stick with our somewhat suboptimal convention.

Remark. In the literature one can find several slightly different definitions of a collar and of a collar neighborhood.

(1) In [**Wall2016**, p. 32] the author works with $\partial N \times [0,1]$ instead of $[0,1] \times \partial M$. As we saw in the Product Orientation Proposition 25.22 (5), for products of two smooth manifolds it is usually preferable to have the smooth manifold with boundary as the first factor. As we just discussed, our orientation convention for collar neighborhoods is suboptimal, but working with $\partial N \times [0,1]$ makes the situation even worse.
(2) In some books, e.g. [**Kos1993**, p. 21] and [**BJ1982**, Definition 13.5], a collar is defined as a smooth embedding $\chi\colon [0,1) \times \partial M \to M$ such that $\chi(0,P) = P$ for all $P \in \partial M$. If we restrict a collar $\chi\colon [0,1] \times \partial M \to M$ to $[0,1) \times \partial M$ then this is evidently a smooth embedding. But as we will see in Exercise 28.3, not every smooth embedding $f\colon [0,1) \times \partial M \to M$ can be extended to a smooth embedding $[0,1] \times \partial M \to M$. We prefer to work with our definition since it makes it easier to formulate in what sense collars are unique, see the Uniqueness of Collar-Proposition **??**.
(3) Our condition (b), namely that a collar neighborhood needs to be closed, is non-standard. If ∂M is compact, which is anyway the case in most situations, the image of any smooth embedding $[0,1] \times \partial M \to M$ is a closed subset by the Product Topology

Properties Proposition 5.6, the Smooth Manifold Boundary Proposition 19.26 (3b), the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21. Thus the condition only has content if ∂M is non-compact. It seems to the author that in the case of non-compact boundary it is often implicitly assumed that any subset that satisfies (a) is actually closed. But in general this is not the case. For example, in the figure below we consider $M = \{(x, y) \in \mathbb{R}^2 \,|\, y \geq 0\}$ and the image of a smooth embedding $[0, 1] \times \partial M$ that does not contain a certain point P, but such that P lies in the closure of the smooth embedding. In other words, the image of $[0, 1] \times \partial M$ is not a closed subset of M. In Lemma 28.7 we will see that this issue can be resolved in a suitable sense.

Now, after this lengthy discussion of the notion of a collar, we finally get a chance to state the Smooth Collar Neighborhood Theorem.

Theorem 28.3. (Smooth Collar Neighborhood Theorem) Let M be a smooth manifold. For any neighborhood V of the boundary ∂M there exists a collar $\chi\colon [0, 1]\times\partial M \to M$ with $\chi([0, 1] \times \partial M) \subset V$.

We will provide a proof of the Smooth Collar Neighborhood Theorem 28.3 in the next section. In the remainder of this section we will discuss the Smooth Collar Neighborhood Theorem 28.3 and some of its consequences.

Remark.

(1) The Smooth Collar Neighborhood Theorem 28.3, sometimes in slightly different flavors, is proved in almost every book dealing with the topology of smooth manifolds. In particular proofs are provided in [**Wall2016**, Theorem 1.5.5], [**Lee2002**, Theorem 9.25], [**BJ1982**, Theorem 13.6], [**Muk2015**, Theorem 7.2.13], [**Miln1965b**, Corollary 3.5] and [**Kos1993**, Theorem I.7.3]. As we mentioned above, for non-compact smooth manifolds our definition of a collar is stricter than in the literature. In Lemma 28.7 we will see that this is not really an issue.

(2) In Project 35.1 we will give an alternative proof of the Smooth Collar Neighborhood Theorem 28.3.

(3) In Theorem **??** we will state a refinement of the Smooth Collar Neighborhood Theorem 28.3 which can also take into account submanifolds. Furthermore in the Uniqueness of Collar-Proposition **??** we will see that collars of compact smooth manifolds are unique in a suitable sense.

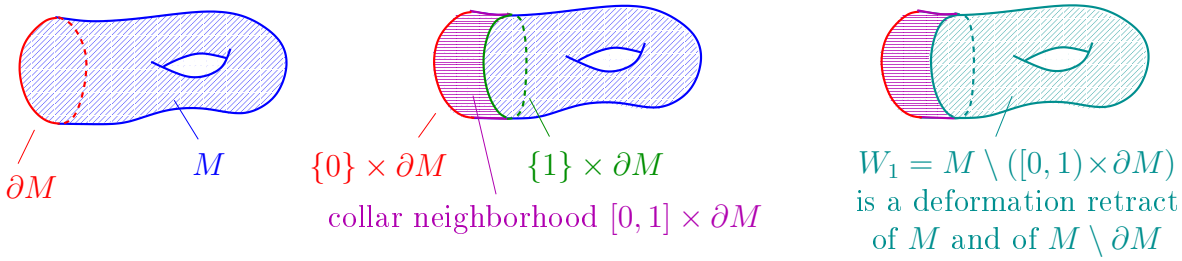
(4) The proof of the Smooth Collar Neighborhood Theorem 28.3 that we will provide does not generalize to the setting of topological manifolds. Nonetheless, in the Topological Collar Neighborhood Theorem 75.5 we will generalize the above theorem to the setting of topological manifolds, using a different argument. The approach taken in the proof for topological manifolds can, after some finetuning, also be used to

prove the above Smooth Collar Neighborhood Theorem 28.3. On the other hand, the argument which we use in this chapter for smooth manifolds has the advantage that it can also be used to prove several refinements, e.g. Theorem **??** and the Uniqueness of Collar-Proposition **??**.

(5) At least for the case that ∂M is compact one can also prove the Smooth Collar Neighborhood Theorem 28.3 using the Smooth Manifold Product Theorem 138.2.

The following lemma summarizes a few more or less technical properties of collar neighborhood. The lemma in particular justifies the name "collar neighborhood".

Lemma 28.4. (Basics-of-Collars Lemma) Let M be an n-dimensional smooth manifold. Suppose we are given a collar $\chi\colon [0,1]\times\partial M \to M$. As above we identify $[0,1]\times\partial M$ with its image in M.



(1) Let $t \in (0,1]$ and let A be a union of components of ∂M. The subset $[0,t)\times A$ is an open subset of M. In particular $[0,t)\times A$ and $[0,t]\times A$ are neighborhoods of A in the sense of the definition on page 113.

(2) Given any $t \in (0,1]$ the subset $W_t := M \setminus ([0,t)\times\partial M)$ is a codimension-zero submanifold of M with boundary given by $\{t\}\times\partial M$.

(3) (a) For every $t \in (0,1]$ the submanifold $W_t = M \setminus ([0,t)\times\partial M)$ is a deformation retract of M and it is a deformation retract of $M \setminus \partial M$.

(b) For every $t \in [0,1)$ there exists a *smooth* homotopy[290] $F\colon M\times[0,1]\to M$ with the following properties:

- F is a homotopy rel $W_1 = M \setminus ([0,1)\times\partial M)$,
- $F_0 = \mathrm{id}$,
- for each $P \in \partial M$ and $s \in [0,1]$ we have $F_s(P) \subset [0,1]\times\{P\}$,
- $F_1(M) \subset W_t$.

Proof.

(1) This statement is an immediate consequence of the Codimension-Zero Smooth Embedding Proposition 24.16 (1).

(2) Let $t \in [0,1]$. By hypothesis $\chi([0,1]\times\partial M)$ is a closed subset of M. It follows from the Open -Closed Inclusion Lemma 2.10 that $\chi([0,t]\times\partial M)$ is also a closed subset of M. The desired statement follows from this observation together with the Codimension-Zero Smooth Embedding Proposition 24.16 (2).

[290] By the Smooth Manifold Product Proposition 20.6 we can view $M\times[0,1]$ as a smooth manifold (possibly with corner). Thus it makes sense to say that the map $F\colon M\times[0,1]\to M$ is smooth.

(3) (a) Let $t \in (0,1]$. We consider the map

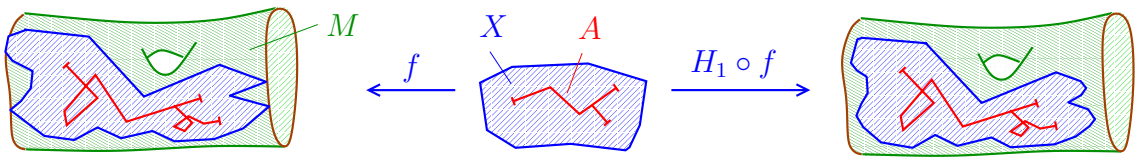
$$\begin{array}{rcl} F\colon M \times [0,1] & \to & M \\ (Q,s) & \mapsto & \begin{cases} ((1-s)\cdot u + s\cdot t, R), & \text{if } Q = (u,R) \in [0,t] \times \partial M, \\ Q, & \text{if } Q \in W_t. \end{cases} \end{array}$$

Note that by definition the collar neighborhood $[0,1]\times\partial M$ is a closed subset of M and that we know by (1) that $M\setminus([0,1)\times\partial M)$ is also a closed subset of M. Since the restriction of F to the products of these closed subsets with $[0,1]$ is continuous we obtain from the Pasting Proposition 2.6 (2) that the map $F\colon M\times[0,1]\to M$ is indeed continuous. This map defines a deformation retraction from M to W_t and also from $M\setminus\partial M$ to W_t.

(b) Let $t \in [0,1)$. Using the Smooth Transition Function Lemma 19.4 one can show easily that there exists a smooth map $\eta\colon [0,1]\to[t,1]$ for which there exists an $\epsilon > 0$ such that $\eta(s) = s$ for all $s \in [1-\epsilon, 1]$. We consider the homotopy

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & M \\ (Q,s) & \mapsto & \begin{cases} ((1-s)\cdot u + s\cdot \eta(u), R), & \text{if } Q = (u,R) \in [0,1] \times \partial M, \\ Q, & \text{if } Q \in W_1. \end{cases} \end{array}$$

It follows from the Smooth Pasting Proposition 19.23 that this map is smooth.[291] It is now clear that this map has all the desired properties. ■



For technical purposes it is at times useful to arrange that maps take values "away from the boundary". In many cases this can be achieved by the following corollary.

Corollary 28.5. (Push-Away-from-Boundary Corollary) Let M be a smooth manifold.

(1) The smooth manifold M is homotopy equivalent to $M\setminus\partial M$. In particular, if ∂M is non-empty, then M is homotopy equivalent to a non-compact n-dimensional smooth manifold without boundary.

(2) (a) Let X be a topological space, let $f\colon X\to M$ be a map and let $A\subset X$ be a (possibly empty) compact subset with $f(A)\subset M\setminus\partial M$. There exists a smooth homotopy $H\colon M\times[0,1]\to M$ rel $f(A)$ with $H_0 = \mathrm{id}$ and with $(H_1\circ f)(X)\subset M\setminus\partial M$.

(b) If X is a smooth manifold and $f\colon X\to M$ is a smooth map, then f is smoothly homotopic to a map $f\colon X\to M\setminus\partial M$.

Proof. We set $M' := M\setminus\partial M$. By the Smooth Collar Neighborhood Theorem 28.3 there exists a collar $\chi\colon[0,1]\times\partial M\to M$.

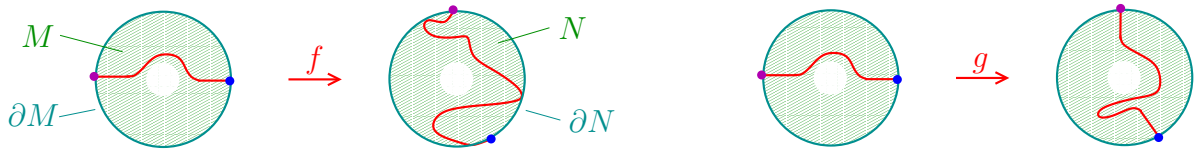
(1) It follows from the Basics-of-Collars Lemma 28.4 (2a) and Lemmas 15.5 and 15.1 that M and M' are homotopy equivalent. Furthermore note that it follows from the

[291] The super vigilant reader will notice that we are really using the obvious extension of the Smooth Pasting Proposition 19.23 to smooth manifolds with corner.

Smooth Manifold Boundary Proposition 19.26 that M' is non-compact, that it is an open subset of M (in particular it is an n-dimensional smooth manifold) and that the smooth manifold M' does not have any boundary.

(2) (a) Since A is compact we obtain from the Compact Image Lemma 2.13 (1) that $f(A)$ is compact. Since $\chi([0,1] \times \partial M)$ is a closed subset we obtain from the elementary Lemma 1.21 that $f(A) \cap \chi([0,1] \times \partial M)$ is also compact. Finally note that it follows from the above discussion, the Compact Image Lemma 2.13 (2) and the hypothesis that $f(A) \subset M \setminus \partial M$ that there exists an $\epsilon \in (0,1]$ such that $\Phi([0,\epsilon] \times \partial M) \cap f(A) = \varnothing$.
By the Basics-of-Collars Lemma 28.4 (3b), applied to the collar $(t,x) \mapsto \chi(t \cdot \epsilon, x)$, there exists a smooth homotopy $H\colon M \times [0,1] \to M$ rel $M \setminus \chi([0,\epsilon] \times \partial M)$ such that $H_0 = \mathrm{id}$ and such that $H_1(M) \subset M \setminus \partial M$.

(b) We pick a smooth homotopy $H\colon M \times [0,1] \to M$ as in (a). The desired smooth homotopy is now given given the map[292]



$$\begin{array}{rcl} X \times [0,1] & \to & M \\ (x,t) & \mapsto & H(f(x),t). \end{array}$$

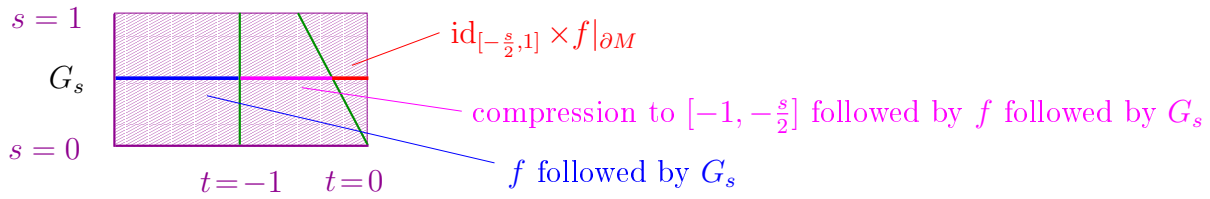
■

We conclude this exhausting discussion of collar neighborhoods with the following technically quite useful lemma.

Lemma 28.6. (Homotopic-to-Product-Near-Boundary Lemma) Let M and N be smooth manifolds with collars $\mu\colon [0,1] \times \partial M \to M$ and $\nu\colon [0,1] \times \partial N \to N$. To simplify the notation we identify $[0,1] \times \partial M$ and $[0,1] \times \partial N$ with their images under μ and ν. Furthermore let $f\colon M \to N$ be a map with $f(\partial M) \subset \partial N$. There exists a homotopy $F\colon M \times [0,1] \to N$ from f to a map g such that the following holds:

(1) For each $t \in [0,1]$ we have $F_t(\partial M) \subset \partial N$.
(2) The map $g\colon M \to N$ has the following two properties:
  (a) For every $(t,P) \in [-\frac{1}{2},0] \times \partial M$ we have $g(t,P) = (t, f(P)) \in [-\frac{1}{2},0] \times \partial N$.
  (b) We have $g^{-1}([-\frac{1}{2},0] \times \partial N) = [-\frac{1}{2},0] \times \partial M$.

Proof. We consider the homotopy



$$\begin{array}{rcl} G\colon N \times [0,1] & \to & N \\ (Q,s) & \mapsto & \begin{cases} (-\frac{s}{2}, \widetilde{Q}), & \text{if } Q = (t,\widetilde{Q}) \in [-\frac{s}{2},0] \times \partial N, \\ Q, & \text{if } Q \in N \setminus ((-\frac{s}{2},0] \times \partial N) \end{cases} \end{array}$$

Note that each G_s "pushes everything in $[-\frac{s}{2},0] \times \partial N$ to $\{-\frac{s}{2}\} \times \partial N$". Now we consider the map

[292] It follows from the Smooth Manifold Product Proposition 20.6 that this map is indeed smooth.

$$\begin{array}{rcl} F\colon M\times[0,1] & \to & N \\ (P,s) & \mapsto & \left(\begin{array}{ll} (t, f(0,\widetilde{P})), & \text{if } P=(t,\widetilde{P}) \text{ with } t\in[-\frac{1}{2}s,0], \\ G_s\big(f\big(\frac{t+\frac{1}{2}s}{1-\frac{1}{2}s},\widetilde{P}\big)\big), & \text{if } P=(t,\widetilde{P})\in[-1,-\frac{1}{2}s], \\ G_s(f(P)), & \text{if } P\notin(-1,0]\times\partial M. \end{array}\right) \end{array}$$

Note that $F_0 = f$. One can now easily verify that this homotopy F has the desired properties. ■

28.3. **Proof of the Smooth Collar Neighborhood Theorem 28.3.** This section is completely dedicated to the proof of the Smooth Collar Neighborhood Theorem 28.3. For non-compact smooth manifolds we will need the following technical lemma which is of interest only for diehard fans of noncompact smooth manifolds and their collars.

Lemma 28.7. Let M be a smooth manifold and let $f\colon [0,1]\times\partial M\to M$ be a smooth embedding such that for every $P\in\partial M$ we have $f(0,P)=P$. There exists a smooth map $\psi\colon \partial M\to(0,1]$ such that the map

$$\begin{array}{rcl} g\colon [0,1]\times\partial M & \to & M \\ (t,x) & \mapsto & f(\psi(x)\cdot t, x) \end{array}$$

is a collar, i.e. it is a smooth embedding such that $g(0,P)=P$ for all $P\in\partial M$ and such that $g([0,1]\times\partial M)$ is a closed subset of M.

Remark.

(1) We had alluded to Lemma 28.7 earlier on page 738 as it allows us navigate between the different notions of a collar for a non-compact smooth manifolds.
(2) Our proof of Lemma 28.7 is based on the proof provided in [**Lee2002b**].

Proof. By the Manifold Exhaustion Lemma 21.2 there exists a smooth map $\mu\colon M\to[0,\infty)$ with the property that given any $C\in\mathbb{R}$ the preimage $f^{-1}([0,C])$ is a compact subset of M. We consider the map

$$\begin{array}{rcl} \varphi\colon \partial M & \to & [0,1] \\ x & \mapsto & \sup\big\{t\in[0,1]\,\big|\,\mu(f(x,s))>\mu(\underbrace{f(x,0)}_{=x})-1 \text{ for all } s\in[0,t]\big\}. \end{array}$$

Using charts one can show fairly easily that the map φ is continuous and that $\varphi(x)>0$ for every $x\in\partial M$. By the Replace-by-Smooth Non-Negative Function Corollary 21.11 there

exists a smooth map $\psi\colon \partial M \to (0,1]$ such that $\psi(x) \in (0, \varphi(x)]$ for all $x \in \partial M$. It suffices to prove the following claim:

Claim. The map
$$\begin{array}{rcl} g\colon [0,1]\times\partial M & \to & M \\ (t,x) & \mapsto & f(\psi(x)\cdot t, x) \end{array}$$
is a smooth embedding such that $g(0,P) = P$ for all $P \in \partial M$ and such that $g([0,1]\times\partial M)$ is a closed subset of M.

Proof. The only statement which requires some thought is to show that $g([0,1]\times\partial M)$ is a closed subset of M. We have

$$M \setminus g([0,1]\times\partial M) = \underbrace{\Big(\bigcup_{C\in\mathbb{R}} \mu^{-1}([0,C))\Big)}_{=M} \setminus g([0,1]\times\partial M) = \bigcup_{C\in\mathbb{R}} \mu^{-1}([0,C)) \setminus g([0,1]\times\partial M)$$

$$= \bigcup_{C\in\mathbb{R}} \underbrace{\mu^{-1}([0,C))}_{\text{open}} \setminus \underbrace{g([0,1]\times(\,\partial M \cap \overbrace{\mu^{-1}([0,C+1])}^{\text{compact}}\,))}_{\substack{\text{compact by Proposition 19.26 (3a)}\\ \text{and Exercise 1.22}}}.$$

$\uparrow$ since $\mu(g(t,x)) > \mu(x,0) - 1$ for all $(t,x) \in [0,1]\times\partial M$

closed by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21

Thus we have shown that $M \setminus g([0,1]\times\partial M)$ is the union of open subsets of M, thus $M \setminus g([0,1]\times\partial M)$ itself is open, i.e. $g([0,1]\times\partial M)$ is closed. ∎

Now we can finally turn to the actual proof of the Smooth Collar Neighborhood Theorem 28.3.

Proof of the Smooth Collar Neighborhood Theorem 28.3. Let M be a smooth manifold and let V be an open neighborhood of ∂M. By the Euclidean Embedding Theorem 27.1 there exists an $n \in \mathbb{N}$ and a proper smooth embedding $\varphi\colon M \to \mathbb{H}^n$. Thus, by the Smooth Embedding Theorem 24.10, we might as well assume that M is a proper smooth submanifold of $\mathbb{H}^n$. By definition of "proper" this means in particular that the inclusion $M \to \mathbb{H}^n$ is a closed embedding. Note that it follows from the Smooth Manifold Boundary Proposition 19.26 that the inclusion $\partial M \to \mathbb{H}^n$ is also a closed embedding.
Our goal is to construct a collar $\chi\colon [0,1]\times\partial M \to M$. In the following three claims we first introduce three auxiliary maps. Afterwards we provide the actual construction of a collar.

Claim 1. The map
$$\begin{array}{rcl} \Omega\colon [0,\infty)\times\partial M & \to & \mathbb{H}^n \\ (t,P) & \mapsto & P + t\cdot e_n \end{array}$$
is smooth and it satisfies $\Omega^{-1}(\partial\mathbb{H}^n) = \{0\}\times\partial M$.

Proof. The two statements are basically obvious. ⊞

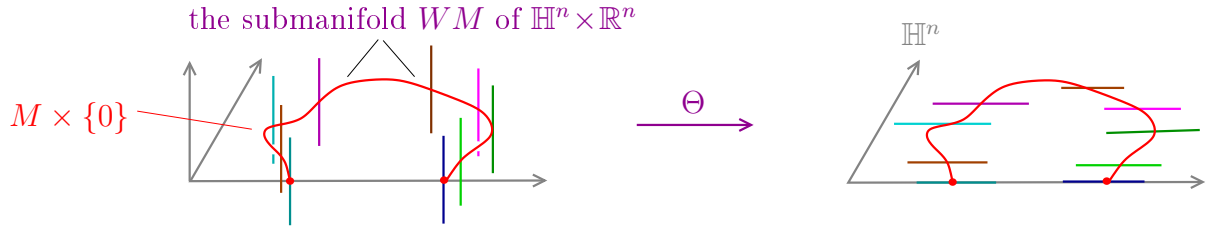
The idea now is to compose the map $\Omega\colon [0,\infty)\times\partial M \to \mathbb{H}^n$ with a projection onto M. This sounds like a case for the Neighborhood Projection Theorem 28.1. But we had formulated - for good reasons - the Neighborhood Projection Theorem 28.1 only for smooth manifolds with *empty boundary*. Therefore we will have to work quite a bit to make the original idea work.

Recall that by the Normal Vectors Lemma 28.2 we know that

$$WM \;:=\; \big\{(P,w)\in\mathbb{H}^n\times\mathbb{R}^n \,\big|\, P\in M \text{ and } w\in\big(\widetilde{\mathrm{T}}_P M\big)^{\perp}\big\}$$

is an n-dimensional submanifold of $\mathbb{H}^n\times\mathbb{R}^n$ with $\partial(WM) = WM\cap(\partial\mathbb{H}^n\times\mathbb{R}^n)$.

Claim 2. We consider the projections



$$\begin{array}{rcl} p\colon \mathbb{H}^n & \to & \mathbb{R}^{n-1} \\ (x_1,\dots,x_n) & \mapsto & (x_1,\dots,x_{n-1}) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} q\colon \mathbb{H}^n & \to & \mathbb{R}_{\geq 0} \\ (x_1,\dots,x_n) & \mapsto & x_n. \end{array}$$

The map[293]

$$\begin{array}{rcl} \Theta\colon WM & \to & \mathbb{R}^{n-1}\times\mathbb{R}_{\geq 0} = \mathbb{H}^n \\ (P,w) & \mapsto & (p(P+w), q(P)) \end{array}$$

has the following properties:

(1) For every $P\in\partial M$ the differential $\mathrm{D}\Theta_{(P,0)}\colon \widetilde{\mathrm{T}}_{(P,0)}WM \to \mathbb{R}^n$ is an isomorphism.
(2) $\Theta^{-1}(\partial\mathbb{H}^n) = \partial(WM) = WM\cap(\partial\mathbb{H}^n\times\mathbb{R}^n)$.

Proof. Let $P\in\partial M$. Note that[294]

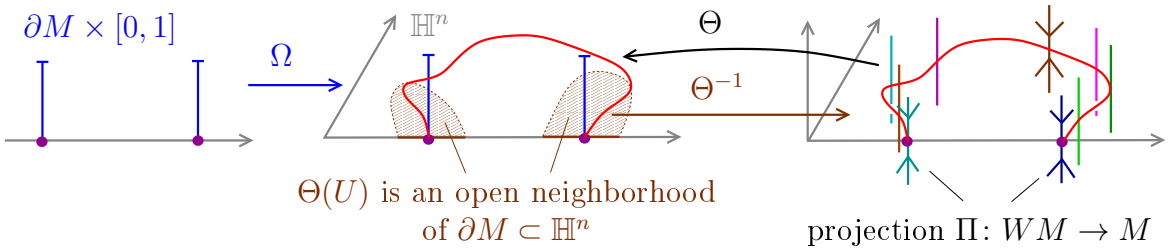
$$\widetilde{\mathrm{T}}_{(P,0)}WM \;=\; \{(v,w)\,|\,v\in\widetilde{\mathrm{T}}_P M \text{ and } w\in\big(\widetilde{\mathrm{T}}_P M\big)^{\perp}\}.$$

Recall that by definition of a proper smooth submanifold we know that $\widetilde{\mathrm{T}}_P M\subsetneq\mathbb{R}^{n-1}\times\{0\}$. Using these two observations one can easily prove (1). The second statements follow easily from the definitions. ⊞

Claim 3. The map

$$\begin{array}{rcl} \Pi\colon WM & \to & M \\ (P,w) & \mapsto & P \end{array}$$

is smooth and it satisfies $\Pi^{-1}(\partial M) = \partial(WM) = WM\cap(\partial\mathbb{H}^n\times\mathbb{R}^n)$.



Proof. It follows from the Smooth Manifold Product Proposition 19.31 together with the Submanifold Smooth Structure Lemma 19.24 that $\Pi\colon WM\to M$ is smooth. The statement regarding $\Pi^{-1}(\partial\mathbb{H}^n)$ follows easily from the definitions. ⊞

As we mentioned above, the inclusion $\partial M\to\mathbb{H}^n$ is a closed embedding. Evidently for each $P\in\partial M$ we have $\Theta(P,0) = P$. It follows that the restriction of Θ to $\partial M\times\{0\}$ is a closed embedding. Furthermore note that it follows from Claim 2 (1) and (2), together with the Inverse Mapping Theorem 24.1, that $\Theta\colon WM\to\mathbb{H}^n$ is a local diffeomorphism at each $(P,0)$ with $P\in\partial M$. These arguments show that we can apply the Neighborhood Smooth Embedding Theorem 21.13 to $\Theta\colon WM\to\mathbb{H}^n$ and the closed subset $\partial M\times\{0\}$. We obtain

[293] The map $\Theta\colon WM\to\mathbb{H}^n$ is related to the map $\Xi\colon WM\to\mathbb{R}^n$, $(P,w)\mapsto P+w$ that we introduced in the Normal Vectors Lemma 28.2. The advantage of Θ is that it satisfies $\Theta^{-1}(\partial\mathbb{H}^n) = \partial(WM) = WM\cap(\partial\mathbb{H}^n\times\mathbb{R}^n)$ which is not true for Ξ.

[294] This equality can be seen as follows. One can easily verify that the right hand side is contained in the left hand side. Both are n-dimensional vector subspaces, thus they have to be the same.

an open neighborhood U of $\partial M \times \{0\} \subset WM$ such that $\Theta(U)$ is an open neighborhood of $\Theta(\partial M \times \{0\}) = \partial M \subset \mathbb{H}^n$ and such that $\Theta\colon U \to \Theta(U)$ is a diffeomorphism.

Claim 4. There exists a smooth map $\mu\colon \partial M \to (0,\infty)$ such that for each $P \in \partial M$ we have $\Omega([0,\mu(P)] \times \{P\}) \subset \Theta(U)$.

Proof. First note that it follows from the fact that $\Theta(U)$ is an open subset of $\mathbb{H}^n$ and the definition of the product topology on $[0,1] \times \partial M$ that for every $P \in \partial M$ there exists a $\mu > 0$ and an open neighborhood V of $P \in \partial M$ such that $\Omega([0,\mu] \times V) \subset \Theta(U)$. The claim follows from this observation together with the Replace-by-Smooth Non-Negative Function Corollary 21.11 (2). ⊞

For the reader's convenience we summarize all the maps involved so far:

$$\begin{array}{ccccccc} \{(t,P)\,|\,t \in [0,\mu(P)]\} & \xrightarrow{\Omega} & \Theta(U) & \underset{\cong}{\overset{\Theta}{\leftarrow}} & U & & \\ \downarrow & & \downarrow & \overset{\Theta^{-1}}{\curvearrowright} & \downarrow & & \\ [0,\infty) \times \partial M & \xrightarrow{\Omega} & \mathbb{H}^n & \xleftarrow{\Theta} & WM & \xrightarrow{\Pi} & M. \end{array}$$

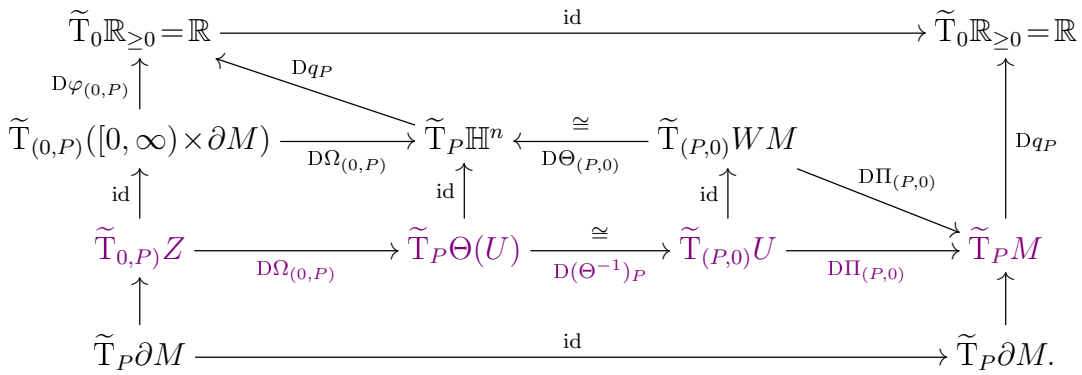
The following claim now finally proclaims that we can find a collar.

Claim 5. There exists a smooth map $\nu\colon \partial M \to (0,\infty)$ such that for each $P \in \partial M$ we have $\nu(P) \le \mu(P)$ and such that the map[295]

$$\begin{array}{rcl} [0,1] \times \partial M & \to & M \\ (t,P) & \mapsto & (\Pi \circ \Theta^{-1} \circ \Omega)((\nu(P) \cdot t, P)) \end{array}$$

is a collar.

Proof. First we consider the map



$$\begin{array}{rcl} g\colon \overbrace{\{(t,P) \in [0,\infty) \times \partial M\,|\,t \in [0,\mu(P)]\}}^{=:Z} & \to & M \\ (t,P) & \mapsto & (\Pi \circ \Theta^{-1} \circ \Omega)(t,P). \end{array}$$

We make the following observations:

(1) It follows immediately from the definitions of the various maps that for every $P \in \partial M$ we have $g(0,P) = P$. Since ∂M is a closed subset of $\mathbb{H}^n$ we see that the restriction of g to $\partial M \times \{0\}$ is a closed embedding.

[295] Note that it follows from $\nu(P) \le \mu(P)$ that $\Omega(\nu(P) \cdot t, P) \in \Theta(U)$. Thus $(\Pi \circ \Theta^{-1} \circ \Omega)((\nu(P) \cdot t, P))$ is indeed defined.

(2) We now want to show that for each $P \in \partial M$ the differential $\mathrm{D}g_{(0,P)} \colon \widetilde{\mathrm{T}}_{(0,P)}Z \to \widetilde{\mathrm{T}}_P M$ is an isomorphism. To do so we consider the following diagram:

We make the following clarifications and observations:

- As before we denote by $q \colon \mathbb{H}^n \to \mathbb{R}_{\geq 0}$ the projection onto the last coordinate.
- We denote by $\varphi \colon [0,\infty) \times \partial M \to \mathbb{R}_{\geq 0}$ the map that is given by the projection onto the first factor.
- The maps that have no names are the differentials of the obvious inclusions.
- It follows immediately from the definitions that $q \circ \Theta = q \circ \Pi \colon WM \to \mathbb{R}_{\geq 0}$ and that $q \circ \Omega = \varphi \colon [0,\infty) \times \partial M \to \mathbb{R}_{\geq 0}$. Using these two observations and using the chain rule one can easily verify that the diagram commutes.
- The composition of the purple horizontal maps is precisely the map $\mathrm{D}g_{(0,P)}$.
- It is straightforward to verify that the vertical sequence to the left is exact.[296]
- It follows easily from the definition of a proper submanifold that the vertical sequence to the right is exact.

A gentle stroll through the diagram now implies that $\mathrm{D}g_{(0,P)} \colon \widetilde{\mathrm{T}}_{(P,0)}Z \to \widetilde{\mathrm{T}}_P M$ is indeed an isomorphism.

(3) It follows immediately from the corresponding statements in Claim 1, 2 and 3 that $g^{-1}(\partial M) = \partial M \times \{0\}$.

It follows from (2) and (3), together with the Inverse Mapping Theorem 24.1, that for each $P \in \partial M$ the map g is a local diffeomorphism at $(0,P)$. Furthermore, using (1), we obtain from the Neighborhood Smooth Embedding Theorem 21.13 that there exists an open neighborhood Y of $\{0\} \times \partial M \subset Z = \{(t,P) \in [0,\infty) \times \partial M \,|\, t \in [0,\mu(P)]\}$ such that $g \colon Y \to M$ is a smooth embedding. After possibly replacing $Y \cap V$ where V is the given neighborhood of ∂M - the reader surely remembers that we are given such a neighborhood - we can assume that $Y \subset V$.

It follows again from Lemma 28.7 together with the Replace-by-Smooth Non-Negative Function Corollary 21.11 (2) that there exists a smooth map $\nu \colon \partial M \to (0,\infty)$ such that the following three conditions are satisfied:

(1) For each $P \in \partial M$ we have $\nu(P) \leq \mu(P)$.
(2) The image of $\{(t,P) \in [0,\infty) \times \partial M \,|\, t \in [0,\nu(P)]\}$ under g is a closed subset of M.

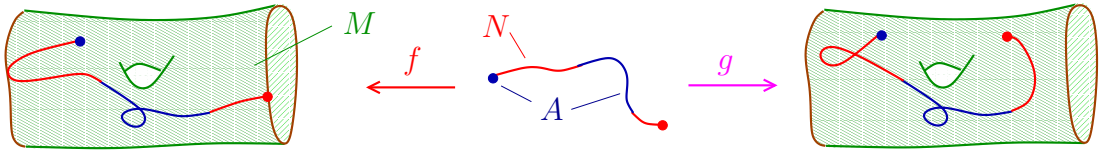
[296] Recall that according to the definition on page 670 a sequence of homomorphisms $U \xrightarrow{\varphi} V \xrightarrow{\psi} W$ between real vector spaces is exact if $\varphi \colon U \to V$ is a monomorphism, if $\psi \colon V \to W$ is an epimorphism and if $\mathrm{im}(\varphi) = \ker(\psi)$.

(3) For each $P \in \partial M$ we have $\{(t, P) \in [0, \infty) \times \partial M \mid t \in [0, \nu(P)]\} \subset Y$.

One can now easily verify that the map of the claim is indeed a collar. ■

Exercises for Chapter 28.

Exercise 28.1. Let X and Y be two topological spaces and suppose that Y is equipped with a metric d. Let $\epsilon > 0$. We say that two maps $f, g\colon X \to Y$ are ϵ-*close* if for all $x \in X$ we have $d(f(x), g(x)) < \epsilon$.



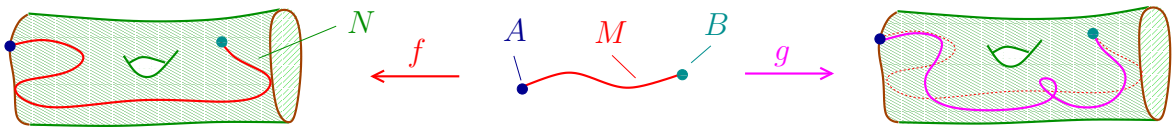
(a) Let M be a smooth submanifold of some $\mathbb{R}^n$ which is closed if viewed as a smooth manifold in its own right. Show that there exists an $\epsilon > 0$ with the following property: If two maps $f, g\colon X \to M$ are ϵ-close, then they are actually homotopic.

(b) Extend the result in (a) to the case that M is a compact smooth submanifold of $\mathbb{R}^n$

(c) Show that the conclusion of (a) and (b) does not hold if we do not assume that M is compact.

(d) Let M be a closed smooth manifold and let d be a metric on M that induces the topology on M. Show that there exists an $\epsilon > 0$ with the following property: If two maps $f, g\colon X \to M$ are ϵ-close, then they are actually homotopic.
Remark. Use Exercise 2.16.

Exercise 28.2. Let M be a smooth manifold, let N be a compact smooth manifold, let $A \subset N$ be closed and let $f\colon N \to M$ be a (smooth) map with $f(A) \subset M \setminus \partial M$. Show that f is (smoothly) homotopic rel A to a map $g\colon N \to M \setminus \partial M$.
Remark. This exercise can be viewed as a smooth analogue of the Push Away From Boundary Lemma 18.13. In particular one can use it to show again that if M is path-connected, then $M \setminus \partial M$ is also path-connected.



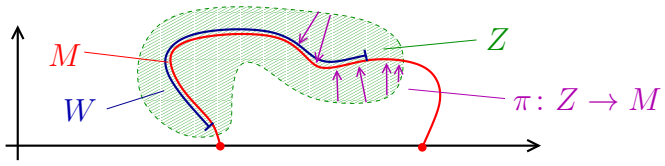
Exercise 28.3. Give an example of a smooth manifold M together with a smooth embedding $\chi\colon [0, 1) \times \partial M \to M$ such that $\chi(0, P) = P$ for all $P \in \partial M$, which cannot be extended to a smooth embedding $f\colon [0, 1] \times \partial M \to M$.

Exercise 28.4. Show that there is no smooth retraction from $[0, 2]$ to $[0, 1]$. More precisely, show that there is no smooth map $f\colon [0, 2] \to [0, 1]$ which satisfies $f(x) = x$ for all $x \in [0, 1]$.

Exercise 28.5. Let M be a compact smooth manifold and let N be any smooth manifold. Furthermore let A be a union of components of ∂M. We set $B := \partial M \setminus A$. Show that for every (smooth) map $f\colon M \to N$ with $f(A) \subset \partial N$ and with $f(B) \subset N \setminus \partial N$ there exists a (smooth) homotopy $F\colon M \times [0, 1] \to N$ rel ∂M from $f\colon M \to N$ to a map $g\colon M \to N$ such that $g^{-1}(\partial N) = A$.

Exercise 28.6. Let M be a smooth manifold and let A and B be two distinct boundary components. Show that there exists a map $f\colon M \to [0, 1]$ such that $f|_A \equiv 0$ and such that

$f|_B \equiv 1$.
Remark. One can prove this statement easily using Urysohn's Lemma 21.7 for Manifolds. But it is more fun to prove it using the Smooth Collar Neighborhood Theorem 28.3.



Exercise 28.7. Let M be a smooth manifold and let $f\colon \partial M \to S^n$ be a map. Show that there exists a smooth map $g\colon M \to \overline{B}^{n+1}$ with $g|_{\partial M} = f$.

Exercise 28.8. Show that given any n-dimensional smooth manifold M there exists an n-dimensional smooth manifold N with $\partial N = \varnothing$ and a smooth embedding $\varphi\colon M \to N$ such that $\varphi(M)$ is a closed subset of N.
Hint. You could take $N = M \setminus \partial M$.

Exercise 28.9. Let M be a proper smooth manifold of some $\mathbb{H}^n$ and let $W \subset M$ be a closed subset with $W \cap \partial M = \varnothing$. Show that there exists a smooth neighborhood Z of $W \subset \mathbb{R}^n$ with $Z \cap \partial M = \varnothing$ and a smooth map $\pi\colon Z \to M$ which has the following two properties:

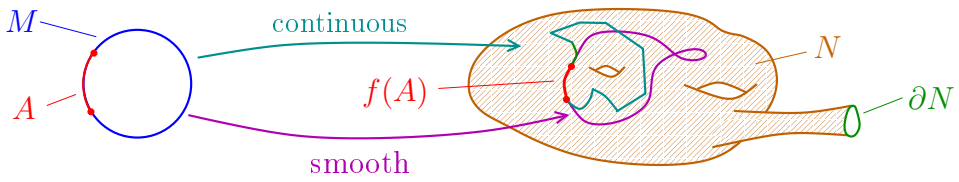
(1) for each $P \in W$ we have $\pi(P) = P$,
(2) π is a submersion, i.e. for each $Q \in Z$ the differential $\mathrm{D}\pi_Q$ is an epimorphism.

Hint. You could try to modify the proof of the Neighborhood Projection Theorem 28.1.

29. The Whitney Approximation Theorem

29.1. **The statement of the Whitney Approximation Theorem.** As we will see later on, there are many ways to construct interesting continuous maps between two smooth manifolds. The following theorem often allows us to "replace" such a continuous map by a smooth map.

Theorem 29.1. (Whitney Approximation Theorem) Let M and N be smooth manifolds and let $f\colon M \to N$ be a map.[297] There exists a homotopy $F\colon M \times [0,1] \to N$ with the following properties:



(1) We have $F_0 = f$.
(2) The map $F_1\colon M \to N$ is smooth.
(3) If there exists a union of components X of ∂M with $f(X) \subset \partial N$, then we can arrange that $F_t(X) \subset \partial N$ for all $t \in [0,1]$.

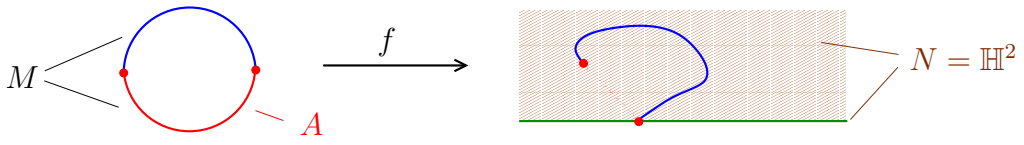
Suppose that f is smooth[298] on a (possibly empty) closed subset A and suppose that there exists an open neighborhood[299] of ∂N that does not intersect $f(A)$. Then we can find a homotopy as above which also has the following property:

(4) The homotopy is a homotopy rel A.

Finally suppose that we are given a map[300] $\rho\colon M \to \mathbb{R}_{\geq 0}$ such that $\rho(x) > 0$ for every $x \notin A$ and suppose that we are given a metric d on N which induces the given topology on N.[301] Then we can find a homotopy F as above that also satisfies the following extra condition:

(5) For every $(x,t) \in M \times [0,1]$ we have $d(F(x,t), f(x)) \leq \rho(x)$.

Remark. Suppose we are in the setting of the Whitney Approximation Theorem 29.1. Let $f\colon M \to N$ be a map that is injective (respectively surjective, bijective). Now we know that we can find a homotopy from f to some smooth map $F_1 = g\colon M \to N$, but the theorem does not give us any control over whether the smooth map $F_1 = g$ is also injective (respectively surjective, bijective). For example, by the Space-Filling Curve Theorem 6.13 we know that there exists a surjective map $[0,1] \to [0,1]^2$. It follows easily, see also Exercise 6.13, that



[297] Note that M and N are both allowed to have non-empty boundary.
[298] Let M and N be smooth manifolds and let $A \subset M$ be an arbitrary subset. On page 549 we defined what it means for a map $f\colon A \to N$ to be smooth.
[299] This condition is satisfied if A is compact and $f(A) \cap \partial N = \varnothing$. Indeed, by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 we know that $f(A)$ is closed. Furthermore by the Smooth Manifold Boundary Proposition 19.26 we know that ∂N is closed. Finally note that by the Manifold Paracompact-Normal Proposition 18.9 (2) we know that N is normal. But this implies that there exists an open neighborhood of ∂N that does not intersect $f(A)$.
[300] Evidently we demand, as always, that ρ is continuous.
[301] Note that by the Manifold Metrization Proposition 18.10 we know that such a metric always exists.

there exists also a surjective map $\mathbb{R} \to \mathbb{R}^2$. But, as we will see in Propositions 30.2 and 30.3 there exists no surjective smooth map $\mathbb{R} \to \mathbb{R}^2$.

Example.

(1) Let M be a smooth manifold and let $f\colon [0,1] \to M$ be a path such that the endpoints $f(0)$ and $f(1)$ lie in $M \setminus \partial M$. By the Whitney Approximation Theorem 29.1, applied to f and the closed subset $\{0,1\} \subset [0,1]$, the map f is homotopic rel $\{0,1\}$ to a smooth path from $f(0)$ to $f(1)$. This gives a new proof of the Smooth Path-Connectivity Proposition 19.29 for smooth manifolds with empty boundary.

(2) In the setting of Whitney Approximation Theorem 29.1 (4) we demand that there exists an open neighborhood of ∂N that does not intersect $f(A)$. In the figure below we show a map $f\colon M = S^1 \to \mathbb{H}^2 = N$ which is smooth on $A = S^1_{\leq 0}$ but which cannot be turned into a smooth map without touching the values on A.

Remark. Proofs of various variations of the Whitney Approximation Theorem 29.1 are also provided in [**Lee2002**, Theorem 6.26], [**Lee2002**, Theorem 9.27], [**MTo1997**, Lemma A.9], [**Hirs1976**, Lemma 5.1.5] and [**DFN1985**, Theorem 10.1.2].

Before we turn to the proof of the Whitney Approximation Theorem 29.1 it is worth recalling the following proposition which basically takes care of the case $N = \mathbb{R}^n$.

Proposition 21.10. (Smooth Approximation Proposition) Let M be a smooth manifold and let $f\colon M \to \mathbb{R}^n$ be a map that is smooth on a (possibly empty) closed subset A. Given any map $\eta\colon M \to \mathbb{R}_{\geq 0}$ such that $\eta(x) > 0$ for every $x \notin A$ there exists a smooth map $\widetilde{f}\colon M \to \mathbb{R}^n$ with the following two properties:

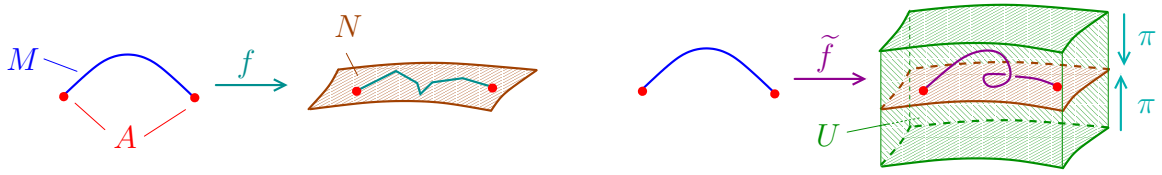
(1) The maps f and $\widetilde{f}$ agree on A.

(2) For every $x \in M$ we have $\|f(x) - \widetilde{f}(x)\| \leq \eta(x)$.

We break the proof of the Whitney Approximation Theorem 29.1 into two parts. First we consider the case that $\partial N = \varnothing$. Afterwards we deal with the case that $\partial N \neq \varnothing$.

Proof of Theorem 29.1 if $\partial N = \varnothing$. Let M be a smooth manifold and let N be a smooth manifold with $\partial N = \varnothing$. Let $f\colon M \to N$ be a map that is smooth on a (possibly empty) closed subset A.

By the Euclidean Embedding Theorem 27.1, together with the Smooth Embedding Theorem 24.10, we can view N as a smooth submanifold of some $\mathbb{R}^n$. Since $\partial N = \varnothing$ we know by the Neighborhood Projection Theorem 28.1 there exists an open neighborhood U of $N \subset \mathbb{R}^n$ together with a smooth retraction $\pi\colon U \to N$.



Since U is open it follows easily from Lemma 10.12 (see also Exercise 2.16) that there exists a continuous map $\mu\colon N \to \mathbb{R}_{>0}$ such that for each $y \in N$ we have $\overline{B}^n_{\mu(y)}(y) \subset U$. Next note that by the Smooth Approximation Proposition 21.10 we know that there exists a map $\widetilde{f}\colon M \to \mathbb{R}^n$ with the following two properties:

(a) The maps f and $\widetilde{f}$ agree on A.
(b) For every $x \in M$ we have $\|f(x) - \widetilde{f}(x)\| \leq \mu(f(x))$.

It is straightforward to verify that the map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & N \\ (x,t) & \mapsto & \pi\big(\underbrace{f(x)\cdot(1-t) + \widetilde{f}(x)\cdot t}_{\in U}\big) \end{array}$$

has all the desired properties (1), (2) and (4). Since $\partial N = \varnothing$ we see that in our current setting Statement (3) is vacuous.

Finally we turn to the proof of (5). Thus suppose that we are given a map $\rho\colon M \to \mathbb{R}_{\geq 0}$ such that $\rho(x) > 0$ for every $x \notin A$. Furthermore suppose that we are given a metric d on N that induces the given topology on N. We sketch how one needs to modify the above argument to obtain that Condition (5) is satisfied, i.e. we show that can arrange that for every $(x,t) \in M \times [0,1]$ we have $d(F(x,t), f(x)) \leq \rho(x)$. First we make the following two observations:

(a) Since $\|-\|$ and d give rise to the same topology we obtain from Lemmas 1.2 and 10.12 (see also Exercise 2.16) that there exists a continuous map $\nu\colon M \to \mathbb{R}_{\geq 0}$ such that for all $x \in M$ and all $y \in N$ with $\|y - f(x)\| \leq \nu(x)$ we have $d(y, f(x)) \leq \rho(x)$.
(b) Since π is smooth one can show without too much effort that there exists a continuous function $\chi\colon N \to \mathbb{R}_{>0}$ such that for every $y \in N$ and every $z \in \overline{B}_{\mu(y)}(y)$ we have $\|\pi(z) - y\| < \chi(y) \cdot \|z - y\|$.

Now we apply the Smooth Approximation Proposition 21.10 to the map

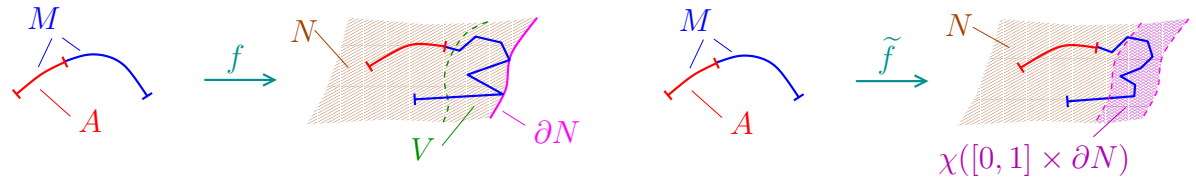
$$\eta(x) \;:=\; \max\Big\{\mu(f(x)), \tfrac{1}{\chi(f(x))} \cdot \nu(f(x))\Big\}$$

and we obtain a suitable smooth map $\widetilde{f}\colon M \to \mathbb{R}^n$. As above one can now easily verify that the map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & N \\ (x,t) & \mapsto & \pi\big(\underbrace{f(x)\cdot(1-t) + \widetilde{f}(x)\cdot t}_{\in U}\big) \end{array}$$

has all the desired properties. ■

Proof of Theorem 29.1 if $\partial N \neq \varnothing$ and $X = \varnothing$. Let M be a smooth manifold and let N be a smooth manifold with $\partial N \neq \varnothing$. Let A be a (possibly empty) closed subset such that there exists an open neighborhood V of ∂N which satisfies $f(A) \cap V = \varnothing$. Finally let $f\colon M \to N$ be a map that is smooth on A.



Note that by the Smooth Collar Neighborhood Theorem 28.3 there exists a collar $\chi\colon [0,1] \times \partial N \to N$ with $\chi([0,1] \times \partial N) \subset V$. As in the proof of the Basics-of-Collars

Lemma 28.4 (3a) we consider the homotopy

$$\begin{array}{rcl} G\colon N\times[0,1] & \to & N \\ (Q,s) & \mapsto & \begin{cases} \chi((1-s)\cdot u+s,R), & \text{if } Q=\chi(u,R)\in[0,1]\times\partial N, \\ Q, & \text{if } Q\in N\setminus\chi([0,1]\times\partial N) \end{cases} \end{array}$$

which describes the "obvious" deformation retraction from N to $N\setminus\chi([0,1)\times\partial N)$. Since $\chi([0,1]\times\partial N)\subset V$ and since $f(A)\cap V=\varnothing$ we see that G gives rise to a homotopy rel A from $f=G_0\circ f$ to $\widetilde{f}:=G_1\circ f$. Thus we have shown that f is homotopic rel A to a map $\widetilde{f}$ that takes values in $\widetilde{N}:=N\setminus\partial N$. By the Smooth Manifold Boundary Proposition 19.26 we know that $\widetilde{N}$ is a smooth manifold without boundary. Thus – by the above discussion of maps to smooth manifolds without boundary – we see that the map $\widetilde{f}\colon G_1\circ f\colon M\to\widetilde{N}$ is homotopic rel A to a smooth map $M\to\widetilde{N}$.

Finally suppose that we are given a map $\rho\colon M\to\mathbb{R}_{>0}$ and suppose that we are given a metric d on N that induces the given topology on N. Dealing with these extra constraints requires a more careful choice of γ. We leave it to the reader to fiddle around with our argument to produce a homotopy that also satisfies Condition (5). ■

Proof of Theorem 29.1 if $\partial N\neq\varnothing$ and $X\neq\varnothing$. We now suppose that there exists a union of components X of ∂M with $f(X)\subset\partial N$. We need to show that we can arrange that $F_t(X)\subset\partial N$ for all $t\in[0,1]$.

By the Smooth Collar Neighborhood Theorem 28.3 there exist collars $\mu\colon[0,1]\times X\to M$ and $\nu\colon[0,1]\times\partial N\to N$. As above we consider the homotopy

$$\begin{array}{rcl} G\colon N\times[0,1] & \to & N \\ (Q,s) & \mapsto & \begin{cases} \nu((1-s)\cdot u+s,R), & \text{if } Q=\nu(u,R)\in[0,1]\times\partial N, \\ Q, & \text{if } Q\in N\setminus\nu([0,1]\times\partial N). \end{cases} \end{array}$$

We write $\widetilde{f}:=f|_X$. Since $\widetilde{f}\colon X\to\partial M$ is a map between smooth manifolds without boundary we know by the above that there exists a homotopy $\widetilde{F}\colon X\times[0,1]\to\partial M$ with $\widetilde{F}_0=\widetilde{f}$ such that $\widetilde{F}_1\colon X\to\partial M$ is smooth.

It follows from an elementary argument, see Exercise 14.6 or the Trivial-Near-The-Ends-Lemma 33.4, that we can modify the homotopy $\widetilde{F}$ such that there exists an $\epsilon>0$ such that $\widetilde{F}_t=\widetilde{F}_1$ for all $t\in[1-\epsilon,1]$. Next we consider the homotopy[302]

$$\begin{array}{rcl} H\colon M\times[0,1] & \to & N \\ (x,t) & \mapsto & \begin{cases} G(x,t), & \text{if } x\notin\mu(X\times[0,1]), \\ G\big(f\big(\mu\big(y,\frac{s-\frac{t}{2}}{1-\frac{t}{2}}\big)\big),t\big) & \text{if } x=\mu(y,s) \text{ with } (y,s)\in X\times[\frac{t}{2},1], \\ \nu(\widetilde{F}(y,t-2s),2s) & \text{if } x=\mu(y,s) \text{ with } (y,s)\in X\times[0,\frac{t}{2}]. \end{cases} \end{array}$$

[302]This formula for H is clearly unreadable. Nonetheless, one can easily plug in the neuralgic values and see, using the Pasting Proposition 2.6, that this map is indeed continuous.

We set $h := H_1 \colon M \to N$. Note that h is smooth on the closed subset $\mu([0, \frac{\epsilon}{2}] \times \partial M)$. We set $\widetilde{M} := M \setminus \mu([0, \frac{\epsilon}{4}) \times \partial M)$ and consider the closed subset $\widetilde{A} := \mu([\frac{\epsilon}{4}, \frac{\epsilon}{2}] \times \partial M) \subset \widetilde{M}$.

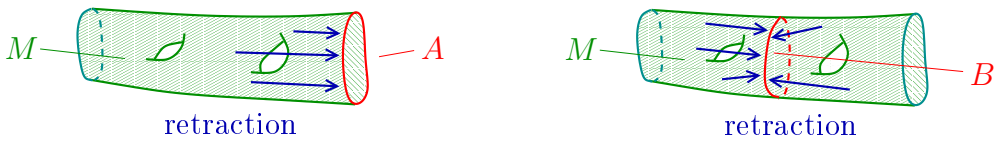
Note that $h(\widetilde{M}) \subset N \setminus \partial N$ and note that h is smooth on $\widetilde{A}$. Thus we can apply the first case to $h|_{\widetilde{M}} \colon \widetilde{M} \to N$ and we see that $h|_{\widetilde{M}}$ is homotopic rel $\widetilde{A}$ to a smooth map. We extend this smooth map via h to $\partial M \times \mu([0, \frac{\epsilon}{4}])$ to obtain a map that is defined on all of M.

Note that the resulting map is smooth on the open subsets $M \setminus \mu([\frac{\epsilon}{4}, \frac{\epsilon}{2}) \times \partial M)$ and $\mu([0, \frac{\epsilon}{2}) \times \partial M)$. Thus it follows from the Smooth Pasting Proposition 19.23 that this map is smooth.

Some adjustments of the above argument can also take into account the presence of a closed subset A and a map $\rho \colon M \to \mathbb{R}_{>0}$ and a metric d on N. We leave this fun task to the reader who is surely tired of reading other people's proofs. ■

29.2. **Consequences of the Whitney Approximation Theorem 29.1.** In this section we formulate and prove several straightforward but useful consequences of the Whitney Approximation Theorem 29.1.

Proposition 29.2. (Replace-by-Smooth-Fixed-Point-Free Map Proposition) Let M be a smooth manifold. Every map $f \colon M \to M$ without fixed points is homotopic to a *smooth* map $g \colon M \to M$ without fixed points.



Proof. Let M be a smooth manifold and let $f \colon M \to M$ be a map without fixed points. By the Manifold Metrization Proposition 18.10 there exists a metric d on M that induces the given topology on M. Given $x \in M$ we set $\rho(x) := d(x, f(x))$. Note that it follows from the Metric-is-Continuous Lemma 6.1 that ρ is continuous. By the Whitney Approximation Theorem 29.1 there exists a homotopy $F \colon M \times [0,1] \to M$ with $f = F_0$ such that $g := F_1$ is a smooth map $g \colon M \to M$ that satisfies the inequality $d(f(x), g(x)) < \rho(x)$ for every $x \in M$. From the triangle inequality we obtain that $d(x, g(x)) > 0$ for every $x \in M$. In other words, g has no fixed points. ■

For the reader's convenience we recall the following definition from page 433.

Definition. Let X be a topological space. We say a subset $A \subset X$ is a retract of X if there exists a retraction $r \colon X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

Proposition 29.3. (Replace-by-Smooth Retraction Proposition) Let M be a smooth manifold.

(1) Let A be a union of boundary components. If there exists a retraction $f \colon M \to A$, then there exists also a smooth retraction $g \colon M \to A$.
(2) Let B be a proper submanifold of M. If there exists a retraction $f \colon M \to B$, then there exists also a smooth retraction $g \colon M \to B$.

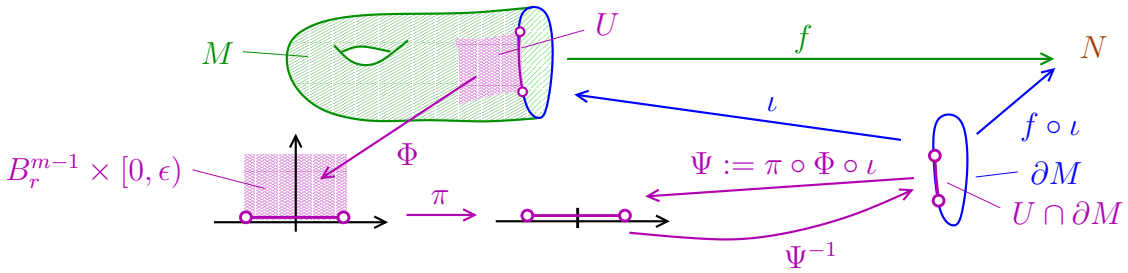
Example. Note that in the Replace-by-Smooth Retraction Proposition 29.3 (2) it is essential that we work with *proper* submanifolds. For example in Exercise 29.5 we will see that

for the smooth manifold $M = \mathbb{R}$ and the smooth submanifold $A = (-\infty, 0]$ there exists a retraction from M to A but there is no smooth retraction.

The proof of the Replace-by-Smooth Retraction 29.3 makes use of the following lemma, which is interesting in its own right.

Lemma 29.4. (Smooth-on-Boundary-Submanifold Lemma) Let $f\colon M \to N$ be a map between two smooth manifolds. We suppose that we are in one of the following two settings.

(1) We are given a union A of boundary components. We equip A with the standard smooth structure that we introduced on page 555
(2) We are given a submanifold A of M. We equip A with the standard smooth structure that we introduced on page 552.



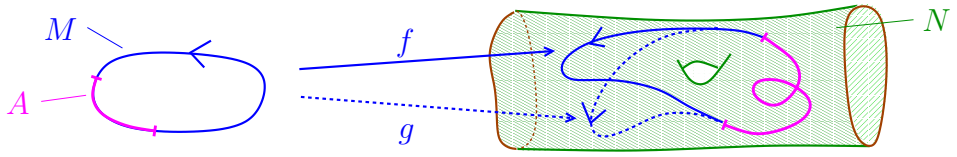
We denote by $\iota\colon A \to M$ the inclusion map. If $f \circ \iota\colon A \to N$ is a smooth map between smooth manifolds, then $f\colon M \to N$ is smooth on the subset $A \subset M$ in the sense of the definition on page 549.

Remark. the Smooth-on-Boundary-Submanifold Lemma 29.4 is basically the content of Exercise 19.24.

Proof of the Smooth-on-Boundary-Submanifold Lemma 29.4. We write $m = \dim(M)$. We provide the proof of Statement (1). It should be clear how to modify the proof to obtain a proof of Statement (2). Now let A be a union of boundary components and let $P \in A$. Note that basically by definition of a boundary point there exists a chart $\Phi\colon U \to B_r^{m-1} \times [0, \epsilon)$ of type (ii) for $P \in M$. We denote by $\pi\colon B_r^{m-1} \times [0, \epsilon) \to B_r^{m-1}$ the natural projection.

The map $\Psi := \pi \circ \Phi \circ \iota\colon U \cap \partial M \to B_r^{m-1}$ is, by definition of the smooth structure on ∂M, a chart for ∂M. We denote by $\Psi^{-1}\colon B_r^{m-1} \to U \cap \partial M$ the inverse.

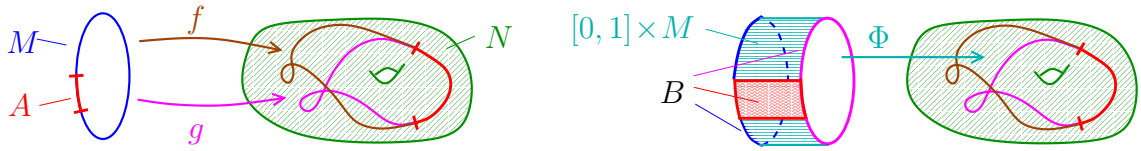
Now we set $\widetilde{f} := (f \circ \iota) \circ \Psi^{-1} \circ \pi \circ \Phi$. This is a composition of smooth maps between smooth manifolds, thus it is smooth. Furthermore, by definition of Ψ we have $\widetilde{f}|_{U \cap \partial M} = f$. We have thus shown that the restriction of $f\colon M \to A$ to A is smooth in the sense of the definition on page 549. ■



Proof of the Replace-by-Smooth Retraction 29.3. We provide the proof of Statement (1). Again it should be clear how to modify the proof to obtain a proof of Statement (2). Let M be an n-dimensional smooth manifold and let A be a union of boundary components. Furthermore let $f\colon M \to A$ be a retraction.

Note that $f|A = \mathrm{id}_A\colon A \to A$ is evidently smooth as a map from the smooth manifold A to itself. It follows from the Smooth-on-Boundary-Submanifold Lemma 29.4 that the

map $f\colon M \to A$ is smooth on A in the sense of the definition on page 549. It follows that we can apply the Whitney Approximation Theorem 29.1 and we obtain a homotopy rel A from f to a smooth map $g\colon M \to A$. Since g is homotopic rel A to the retraction f we see that g is also a retraction. Thus g is the desired smooth retraction from M to A. ■



Proposition 29.5. (Replace-by-Smooth Homotopy Proposition) Let M be a smooth manifold without boundary and let N be a smooth manifold (with or without boundary). Let $f, g\colon M \to N$ be two smooth maps that agree on a (possibly empty) closed subset A. We suppose that there exists an open neighborhood V of ∂N such that $f(A) = g(A)$ is contained in $N \setminus V$.[303] If f and g are homotopic rel A, then there exists also a smooth homotopy rel A between f and g.

Proof. Let $f, g\colon M \to N \setminus \partial N$ be two smooth maps that agree on a closed subset A and let $\Phi\colon M \times [0,1] \to N$ be a homotopy rel A.

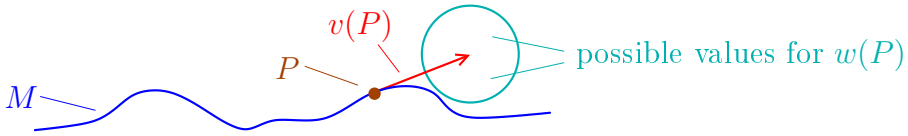
We first consider a special case, namely we suppose that there exists an open neighborhood V of ∂N such that actually $f(M)$ and $g(M)$ are contained in $N \setminus V$.

Note that $B := (M \times \{0\}) \cup (A \times [0,1]) \cup (M \times \{1\})$ is a closed subset of $M \times [0,1]$. Also note that $\Phi(B) \subset N \setminus V$. Since M has no boundary we see that $M \times [0,1]$ is a smooth manifold. Finally note that in Exercise 29.2, which is a slight generalization of the Smooth-on-Boundary-Submanifold Lemma 29.4 (2), we will see that Φ is smooth on B in the sense of the definition on page 549.

It follows from the above that we can apply the Whitney Approximation Theorem 29.1 to the map $\Phi\colon M \times [0,1] \to N$ and the closed subset B and we see that there exists a homotopy rel B from Φ to a smooth map $\Psi\colon M \times [0,1] \to N$. Since it is a homotopy rel B we see that $\Psi|_B = \Phi|_B$. But this implies that Ψ is now a smooth homotopy rel A from $\Psi_0 = \Phi_0 = f$ to $\Psi_1 = \Phi_1 = g$.

Now we consider the general case. Thus now we only suppose that there exists an open neighborhood V of ∂N such that $f(A) = g(A)$ is contained in $N \setminus V$. By a rather modest generalization of the Push-Away-from-Boundary Corollary 28.5 one sees that f and g are smoothly homotopic rel A to maps f' and g' such that there exists an open neighborhood W of ∂N such that $f'(M)$ and $g'(M)$ are contained in $N \setminus W$. By the above special case

[303] This condition is satisfied if M is compact and if f and g take values in $N \setminus \partial N$. Indeed, in this case we know by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 that $f(M) \cup g(M)$ is a closed subset of N that is disjoint from the closed subset ∂N. Since topological manifolds are normal, see Manifold Paracompact-Normal Proposition 18.9 (2), there exists an open neighborhood V of ∂N that is disjoint from $f(M) \cup g(M)$.



we know that f' and g' are smoothly homotopic rel A. Thus in summary we see that f and f', f' and g', g' and g are smoothly homotopic rel A. It is not hard to show that "smoothly homotopic rel A" is an equivalence relation[304], thus we see that f and g are indeed smoothly homotopic rel A. ■

Proposition 29.6. (Replace-by-Smooth Vector Field Proposition) Let M be a smooth manifold. If M admits a nowhere-vanishing vector field, then it also admits a smooth nowhere-vanishing vector field.

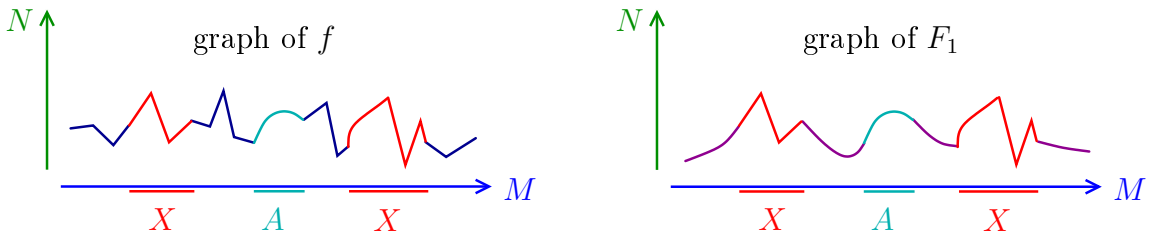
Proof. Let M be a smooth manifold and let v be a nowhere vanishing vector field. By the Euclidean Embedding Theorem 27.1 together with the Smooth Embedding Theorem 24.10 we can view M as a smooth submanifold of some $\mathbb{R}^n$. Furthermore by the Tangent Space-Isomorphism Proposition 23.16 and Lemma 23.18 we can take the view of (smooth) vector fields that take values in the physical tangent spaces $\widetilde{\mathrm{T}}_P M$. Note that each $\widetilde{\mathrm{T}}_P M$ is a subspace of $\mathbb{R}^n$. Thus the vector field v is in particular a map $M \to \mathbb{R}^n$.

We apply the Whitney Approximation Theorem 29.1 to the map $v\colon M \to \mathbb{R}^n$ and the map $\rho\colon M \to \mathbb{R}_{>0}$ that is given by $\rho(x) := \frac{1}{2}\cdot\|v(x)\|$. We obtain a smooth map $w\colon M \to \mathbb{R}^n$ with the following property:

(∗) For every $x \in M$ we have $\|v(x) - w(x)\| \leq \frac{1}{2} \cdot \|v(x)\|$.

Finally we consider the map

$$\begin{array}{rcl} \widetilde{w}\colon M & \to & \mathbb{R}^n \\ P & \mapsto & \text{orthogonal projection of } w(P) \text{ onto } \widetilde{\mathrm{T}}_P M. \end{array}$$



Using an argument as in the proof of the Normal Vectors Lemma 28.2 one can show that this map is in fact smooth. It is elementary to see, using (∗), that for every $P \in M$ we have $\widetilde{w}(P) \neq 0$. Thus we have found a nowhere-vanishing smooth vector field on M. ■

29.3. **More consequences of the Whitney Approximation Theorem 29.1.** We conclude this section with two and a half more technical refinements and consequences of the Whitney Approximation Theorem 29.1. These results are interesting in their own right, but the reader might want to skip them initially.

Proposition 29.7. Let M be a smooth manifold (with or without boundary) and let N be a smooth manifold without boundary. Furthermore let $f\colon M \to N$ be a map. Finally let A and X be disjoint closed subsets of M such that the restriction of f to A is smooth and let $U \subset N$ be an open subset that contains $f(M \setminus X)$. There exists a homotopy $F\colon M \times [0,1] \to N$ with the following properties:

(1) The homotopy is a homotopy rel $X \cup A$.
(2) We have $F_0 = f$.
(3) The restriction of F_1 to the open subset $M \setminus X$ is smooth.[305]
(4) For each $t \in [0,1]$ we have $F_t(M \setminus X) \subset U$.

[304] We will provide the details in the Smooth Isotopy Transitivity Proposition 33.3

Remark. If $X = \varnothing$ and $U = N$, then the statement of Proposition 29.7 is precisely the statement of the Whitney Approximation Theorem 29.1 (1)-(4).

Proof. First we consider the case that $U = N$. By the Manifold Metrization Proposition 18.10 we can pick a metric c on M such that the topology from the metric c agrees with the given topology on M. The same way we can pick a metric d on N. We consider the open subset $W := M \setminus X$ and we view it as a smooth manifold. Since $X \neq \varnothing$ we can consider the function

$$\begin{array}{rcl} \rho\colon W & \to & \mathbb{R}_{\geq 0} \\ w & \mapsto & \rho(w) := c(w, X) = \inf\{c(w, x) \,|\, x \in X\}. \end{array}$$

Since X is closed and since the topology defined by c agrees with the topology on M we see that $\rho(w) > 0$ for every $w \in W$. By the Distance-to-Subspace Lemma 6.2 we know that $\rho\colon M \to \mathbb{R}_{\geq 0}$ is continuous. Since N is a smooth manifold without boundary we can apply the Whitney Approximation Theorem 29.1 to the map $f\colon W \to N$ and we obtain that there exists a homotopy $G\colon W \times [0,1] \to N$ with the following properties:

(a) The homotopy is a homotopy rel A.
(b) We have $G_0 = f|_W$.
(c) The map $G_1\colon W \to N$ is smooth.
(d) For every $(w,t) \in W \times [0,1]$ we have $d(G(w,t), f(w)) \leq \rho(w)$.

It follows easily from (d) and the definition of ρ that the map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & N \\ (x,t) & \mapsto & \begin{cases} G(x,t), & \text{if } x \in W, \\ f(x), & \text{if } x \in X \end{cases} \end{array}$$

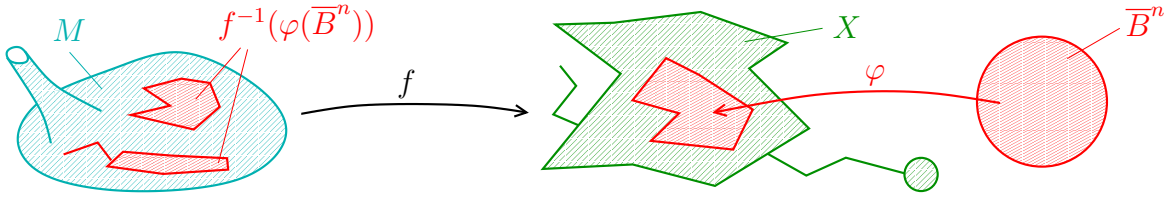
is continuous. Now it is straightforward to verify that this map has all the desired properties.

Finally we consider the case that $U \neq N$. In this case we consider the map

$$\begin{array}{rcl} \rho\colon W & \to & \mathbb{R}_{\geq 0} \\ w & \mapsto & \rho(w) := \min\{c(w, X), d(f(w), N \setminus U)\}. \end{array}$$

Since U is open and since $f(W) \subset U$ we see that ρ is again non-zero everywhere. The rest of the argument is basically the same and it follows from (d) that for each $t \in [0,1]$ we have $F_t(M \setminus X) \subset U$. ∎

[305]Since X is closed we see that $M \setminus X$ is an open subset of M, thus we can view $M \setminus X$ as a smooth manifold in its own right.



Loosely speaking the following proposition says that a map $M \to X$ from a smooth manifold to a topological space X can be made smooth with respect to open balls B^n contained in X.

Proposition 29.8. Let M be a smooth manifold and let $f\colon M \to X$ be a map to a Hausdorff space X. Let $\varphi\colon \overline{B}^n \to X$ be an injective map such that $\varphi(B^n)$ is an open subset of X. Given any $r \in (0,1)$ there exists a map $g\colon M \to X$ with the following properties:

(1) g is homotopic to f rel the complement of $f^{-1}(\varphi(B^n_r))$ in M,
(2) the map

$$\begin{array}{rcl} f^{-1}(\varphi(B^n_r)) & \to & B^n_r \\ x & \mapsto & \varphi^{-1}(g(x)) \end{array}$$

is smooth.

Proof. Since $\overline{B}^n$ is compact, since X is Hausdorff and since $\varphi\colon \overline{B}^n \to X$ is injective we know by the Compact-Hausdorff Proposition 2.17 (2) that φ is a closed embedding. Thus we might as well identify $\overline{B}^n$ with its image under the map $\varphi\colon \overline{B}^n \to X$. Now let $r \in (0,1)$. By the Open -Closed Inclusion Lemma 2.10 we know that B^n_r is also an open subset of X. Furthermore, note that it follows from the fact that X is Hausdorff, together with the Compact-Closed Lemma 1.21 (1), that $\overline{B}^n_r$ and $\overline{B}^n$ are a closed subsets of X. We consider the map

$$\begin{array}{rcl} \alpha\colon M & \to & \overline{B}^n/S^{n-1} \\ x & \mapsto & \begin{cases} f(x), & \text{if } x \in f^{-1}(B^n), \\ [S^{n-1}], & \text{if } x \in M \setminus f^{-1}(B^n). \end{cases} \end{array}$$

Note that α is continuous.[306] Next note that by the Ball-Quotient Sphere Lemma 5.20 we can view $\overline{B}^n/S^{n-1}$ as a smooth manifold such that B^n is a submanifold. Therefore we can apply Proposition 29.7 to the map $\alpha\colon M \to \overline{B}^n/S^{n-1}$ with $A = \varnothing$, with the closed subset $X = M \setminus f^{-1}(B^n_r)$[307] and with the open subset $U = B^n_r \subset N$. We obtain a homotopy $F\colon M \times [0,1] \to \overline{B}^n/S^{n-1}$ with the following properties:

(1) The homotopy is a homotopy rel $X = M \setminus f^{-1}(B^n_r)$.
(2) We have $F_0 = \alpha$.
(3) The restriction of F_1 to $M \setminus X = f^{-1}(B^n_r)$ is smooth.
(4) For each $t \in [0,1]$ we have $F_t(f^{-1}(B^n_r)) \subset B^n_r$.

[306] Indeed, the restrictions of α to the closed subset $M \setminus f^{-1}(B^n)$ is a constant map and the restriction of α to the closed subset $f^{-1}(\overline{B}^n)$ is given by the composition of the map f with the projection $\overline{B}^n \to \overline{B}^n/S^{n-1}$. Therefore we obtain from the Pasting Proposition 2.6 (2) that α is indeed continuous.
[307] Note the discrete subscript "r".

Finally we consider the map

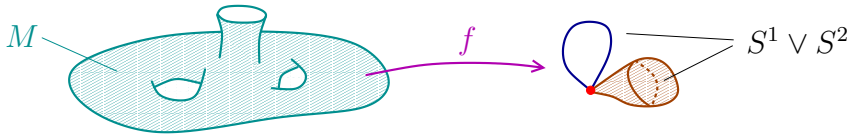
$$\begin{array}{rcl} G\colon M\times[0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} F(x,t), & \text{if } x\in f^{-1}(B^n_r) \\ f(x), & \text{if } x\in M\setminus f^{-1}(B^n_r). \end{cases} \end{array}$$

Note that the restrictions of the map G to the two closed subsets $(M\setminus f^{-1}(B^n_r))\times[0,1]$ and $f^{-1}(\overline{B}^n_r)\times[0,1]$ are continuous.[308] Thus we obtain from the Homotopy Stacking Lemma 14.3 that G is continuous. It is now straightforward to verify that $g := G_1$ has all the desired properties. ■

The following proposition is a slight variation on Proposition 29.8.

Proposition 29.9. Let M be a smooth manifold and let $f\colon M\to X$ be a map to a Hausdorff space X. Let $n\in\mathbb{N}$ and let $*\in S^n$ be a point. Finally let $\varphi\colon S^n\to X$ be an injective map such that $\varphi(S^n\setminus\{*\})$ is an open subset of X. There exists a map $g\colon M\to X$ with the following properties:

(1) g is homotopic to f rel the complement of $f^{-1}(\varphi(S^n\setminus\{*\}))$ in M,



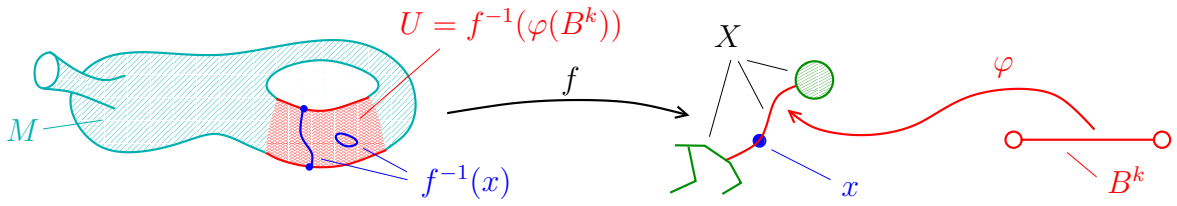
(2) the map

$$\begin{array}{rcl} f^{-1}(\varphi(S^n\setminus\{*\})) & \to & S^n\setminus\{*\} \\ x & \mapsto & \varphi^{-1}(g(x)) \end{array}$$

is smooth.

Proof. We leave it to the reader to modify the proof of Proposition 29.8 to obtain the desired result, see Exercise 29.1. As the reader will notice, in this case there is no need to work with some $r\in(0,1)$. In particular the conclusion we get is slightly more satisfactory. ■

Example. Let $\bigvee_{i=1}^{k} S^{n_i}$ be a wedge of spheres. We denote by $*$ the wedge point. Let M be a smooth manifold and let $f\colon M\to\bigvee_{i=1}^{k} S^{n_i}$ be a map. By iteratively applying Proposition 29.9 altogether k times we see that f is homotopic rel $f^{-1}(*)$ to a map that is smooth on the open sets $f^{-1}(S^{n_i}\setminus\{*\})$, $i=1,\dots,k$.



Lemma 29.10. (Preimage-of-Point-in-Ball Lemma) Let M be an orientable n-dimensional smooth manifold, let $f\colon M\to X$ be a map to some Hausdorff space X, let

[308] For nervous people, like the author, let us verify in slightly greater detail that the restriction of G to $f^{-1}(\overline{B}^n_r)\times[0,1]$ is indeed continuous. First note that by (4) the restriction of the map F to $f^{-1}(B^n_r)\times[0,1]$ takes values in B^n_r. It follows from the Closure-Interior Mapping Lemma 2.5 and Exercise 5.16 that the restriction of the map F to $f^{-1}(\overline{B}^n_r)\times[0,1]$ takes values in the closure of B^n_r in $\overline{B}^n/S^{n-1}$. Since $r\in(0,1)$ we see that the closure equals $\overline{B}^n_r\subset B^n$. Now we see that the restriction of the map G to $f^{-1}(\overline{B}^n_r)\times[0,1]$ equals the composition of the map $F\colon f^{-1}(\overline{B}^n_r)\times[0,1]\to\overline{B}^n_r$ with the inclusion $\overline{B}^n_r\to X$.

$\varphi\colon B^k \to X$ be a map and let $x \in \varphi(B^k)$ be a point such that the following conditions are satisfied:

(1) the image $\varphi(B^k)$ is an open subset of X,
(2) the restriction of f to $f^{-1}(\varphi(B^k))$ is a smooth map.

Then $f^{-1}(x)$ is a proper $(n-k)$-dimensional submanifold of M.

Proof. Note that $U := f^{-1}(\varphi(B^k))$ is an open subset of M, in particular, as discussed in the Open Subset-Submanifold Lemma 19.19, it is a smooth manifold in its own right. It follows from this observation and (3) that we can apply the Regular Value Theorem 26.4. We obtain that $f^{-1}(x)$ is a proper orientable $(n-k)$-dimensional submanifold of U. In particular $f^{-1}(x)$ admits submanifold charts of type (α) and (β), as defined on page 524, with respect to the smooth manifold U. Since U is an open subset of M we see that these submanifold charts are also submanifold charts of the same type for the set $f^{-1}(x)$, viewed as a subset of M.

Since X is by hypothesis Hausdorff we know, by the Points-in-Hausdorff Space Lemma 1.15 (1) that $\{x\}$ is a closed subset of X. Finally, since f is of course understood to be continuous on all of M we obtain that $f^{-1}(x)$ is a closed subset of M. In other words, we have shown that $f^{-1}(x)$ satisfies all the conditions, as set out on page 525, of being a proper submanifold of M. ■

Exercises for Chapter 29.

Exercise 29.1. Provide a proof for Proposition 29.9.

Exercise 29.2. Let M and N be two smooth manifolds. We assume that $\partial M = \varnothing$. Furthermore let $f, g\colon M \to N$ be two smooth maps that agree on a subset A and let $\Phi\colon M \times [0,1] \to N$ be a homotopy rel A. Show that Φ is smooth, in the sense of the definition on page 549, on the subset $(M \times \{0\}) \cup (A \times [0,1]) \cup (M \times \{1\})$ of $M \times [0,1]$.

Exercise 29.3. In the figure below we show an explicit smooth manifold M together with a boundary component A and a submanifold B.

(a) Is A a retract of M?
(b) Is B a retract of M?

Exercise 29.4. Let M be a smooth manifold. The Smooth Path-Connectivity Proposition 19.29 says that every map $\gamma\colon [a,b] \to M$ is homotopic rel the endpoints $\{a,b\}$ to a

smooth map. Give a new proof using the Whitney Approximation Theorem 29.1 and the Smooth Collar Neighborhood Theorem 28.3.

Exercise 29.5. We consider the smooth manifold $\mathbb{R}$ and the smooth submanifold $(-\infty, 0]$.

(a) Show that there exists a retraction from $\mathbb{R}$ to $(-\infty, 0]$.

(b) Show that there is no smooth retraction from $\mathbb{R}$ to $(-\infty, 0]$.

30. Subsets of measure zero

Evidently a smooth manifold does not come with a natural notion of a "measure" or "volume". But perhaps somewhat surprisingly we will see that it makes perfect sense to talk of subsets of "measure zero" and of "full measure" of a smooth manifold. We will see that the image of a smooth map $f\colon M \to N$ with $\dim(M) < \dim(N)$ has "measure zero", and that this implies, that $N \setminus f(M)$ is dense. This fact is surprisingly useful. In particular we will use it to show in the Weak Whitney Embedding Theorem 30.7 that every m-dimensional smooth manifold admits a smooth embedding $M \to \mathbb{R}^{2m+1}$.

The notion of subsets of measure zero also plays an essential role in the formulation of Sard's Theorem 31.1 that we will state and prove in the next chapter.

30.1. Sets of measure zero and the Weak Whitney Embedding Theorem.

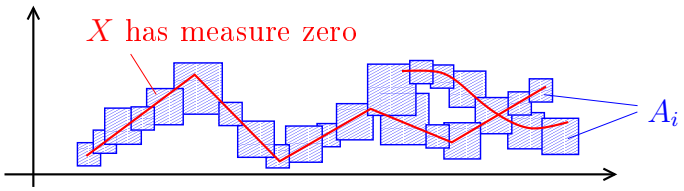
Definition.

(1) Let $r \in \mathbb{R}_{\geq 0}$. An open cube of side length r is any subset of $\mathbb{R}^m$ of the form $(c_1, c_1 + r) \times \cdots \times (c_m, c_m + r)$. We define the volume of such an open cube as

$$\mathrm{vol}((c_1, c_1 + r) \times \cdots \times (c_m, c_m + r)) \;:=\; r^m.$$

(2) Given a countable family $\{r_i\}_{i \in I}$ of non-negative real numbers we set

$$\sum_{i \in I} r_i \;:=\; \sup\left\{ \sum_{j \in J} r_j \;\middle|\; J \subset I \text{ is a finite subset} \right\} \;\in\; \mathbb{R}_{\geq 0} \cup \{\infty\}.$$



(3) Let $X \subset \mathbb{R}^m$ be a subset. We say that X has measure zero if given any $\epsilon > 0$ there exists a countable family $\{A_i\}_{i \in I}$ of open cubes such that $X \subset \bigcup\limits_{i \in I} A_i$ and such that $\sum\limits_{i \in I} \mathrm{vol}(A_i) < \epsilon$. This definition is illustrated in the figure below.

(4) Let M be an m-dimensional smooth manifold.

(a) We say that a subset $X \subset M$ is a subset of measure zero if for every chart $\Phi\colon U \to V$ from the smooth atlas the set $\Phi(X \cap U)$ is a subset of measure zero of $\mathbb{R}^m$.

(b) We say that a subset $X \subset M$ is a subset of full measure if $M \setminus X$ is a subset of measure zero.

(5) Let P be a property of points in M. We say that almost every point in M has property P if the set of points which satisfy P has full measure.

Example.

(1) Let $n \geq 1$ and let $\{P = (p_1, \ldots, p_n)\}$ be a one-point subset of $\mathbb{R}^n$. Since $\{P\}$ is contained in any open cube $(p_1 - \epsilon, p_1 + \epsilon) \times (p_n - \epsilon, p_n + \epsilon)$ of volume $(2\epsilon)^n$ we see that $\{P\}$ is a subset of measure zero.

(2) Let M be a smooth manifold of dimension ≥ 1. Using (a) it is straightforward to show that any finite subset of M has measure zero.

In the following we formulate three propositions which contain almost everything anybody ever wanted to know about subsets of measure zero. We will provide the proofs in the next section.

The definition of "measure zero" is not very practical since one needs to verify a certain condition for every chart. Our first proposition greatly simplifies life, namely it says, that it suffices to consider enough charts to cover all of M.

Proposition 30.1. (Measure Zero-via-Atlas Proposition) Let M be an m-dimensional smooth manifold and let $X \subset M$ be a subset. If there exists a family of smooth charts $\{\Phi_i \colon U_i \to V_i\}_{i\in I}$ with the following two properties:

(1) for each $i \in I$ the set $\Phi_i(X \cap U_i)$ is a subset of measure zero of $\mathbb{R}^m$,
(2) we have $X \subset \bigcup_{i\in I} U_i$,

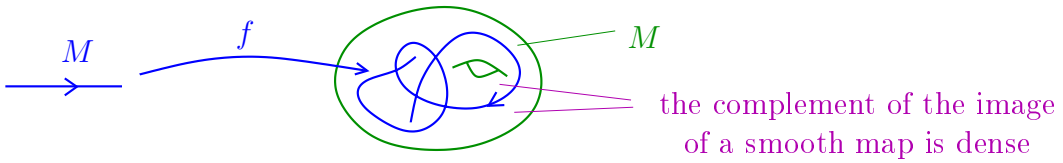
then X has measure zero.

The second proposition summarizes a few basic properties of subsets of measure zero.

Proposition 30.2. (Measure-Zero Properties Proposition) Let M be an m-dimensional smooth manifold.

(1) If X is a subset of measure zero of M, then so is every subset of X.
(2) (a) The union of countably many subsets of measure zero is a subset of measure zero.
    (b) The intersection of countably many subsets of full measure is a subset of full measure.
(3) (a) Let $f \colon M \to N$ be a smooth map between smooth manifolds of the same dimension. If X is a subset of measure zero in M, then $f(X)$ has measure zero in N.
    (b) If $f \colon M \to N$ is a diffeomorphism, then $X \subset M$ has measure zero (respectively full measure) if and only if $f(X)$ does.[309]
(4) If $f \colon M \to N$ is a smooth map between smooth manifolds and if $\dim(M) < \dim(N)$, then $f(M)$ is a subset of measure zero in N. In other words, $N \setminus f(M)$ is a subset of full measure.

Example. Let N be a smooth manifold and let M be a submanifold of N of codimension at least one. By the Submanifold Smooth Structure Lemma 19.24 the inclusion map $\iota \colon M \to N$ is smooth. Therefore it follows from the Measure-Zero Properties Proposition 30.2 (4) that $M \subset N$ has measure zero.



We conclude this section with one last proposition on subsets of measure zero.

Proposition 30.3. (Full Measure-Density Proposition) Let M be an m-dimensional smooth manifold.

(1) Given any subset X of measure zero of M the complement $M \setminus X$ is dense in M.[310]
(2) Every subset of M of full measure is dense in M.

[309] In Exercise 30.3 we will see that the conclusion does not hold if we replace "diffeomorphism" by "homeomorphism".

[310] By Lemma 1.12 this is equivalent to saying that the interior of X is the empty set.

Remark. The above propositions show that on smooth manifolds there is a sensible notion of subsets of measure zero. Denis Sullivan [**Sul1979**, p. 549] showed that for dimensions $n \neq 4$ any n-dimensional topological manifold has an essentially unique "Lipshitz structure", which makes it possible to again introduce a sensible notion of subsets of measure zero. We will not make use of this fact.

30.2. **Proof of Propositions 30.1, 30.2 and 30.3.** We start out with the following self-explanatory definition.

Definition. Let $r \in \mathbb{R}_{\geq 0}$. A closed cube of side length r is any subset of $\mathbb{R}^m$ of the form $[c_1, c_1 + r] \times \cdots \times [c_m, c_m + r]$. We define the volume of such a closed cube as

$$\operatorname{vol}([c_1, c_1 + r] \times \cdots \times [c_m, c_m + r]) \;:=\; r^m.$$

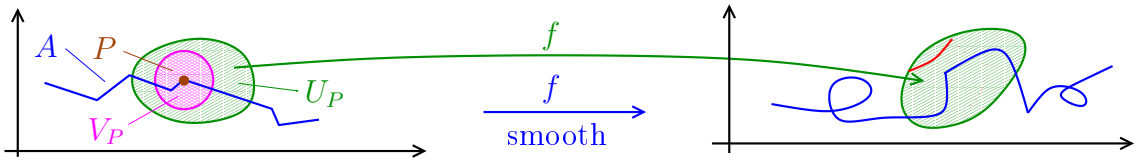
The following lemma contains some very basic statements about subsets of measure zero.

Lemma 30.4. (Measure Zero-Basics Lemma)

(1) If C is a subset of measure zero of $\mathbb{R}^m$, then so is every subset of C.
(2) If $\{C_i\}_{i \in I}$ is countable family of subsets of $\mathbb{R}^m$ of measure zero, then $\bigcup_{i \in I} C_i$ also has measure zero.
(3) Let C be a subset of measure zero of $\mathbb{R}^m$ and let $\sigma \in S_m$ be a permutation. Then
$$\{(x_1, \ldots, x_m) \in \mathbb{R}^m \mid (x_{\sigma(1)}, \ldots, x_{\sigma(m)}) \in C\}$$
also has measure zero.
(4) Let C be a subset of $\mathbb{R}^m$. If given any $\epsilon > 0$ there exists a countable family $\{A_i\}_{i \in I}$ of closed cubes such that $X \subset \bigcup_{i \in I} A_i$ and such that $\sum_{i \in I} \operatorname{vol}(A_i) < \epsilon$, then C has measure zero.

Proof.

(1) This statement is trivial.
(2) Let $\{X_i\}_{i \in I}$ be a countable family of subsets of measure zero of $\mathbb{R}^m$. Using the fact that $\sum_{k \in \mathbb{N}} \frac{1}{2^k} = 1$ it is straightforward to show that $\bigcup_{i \in I} X_i$ is also a subset of measure zero.
(3) This statement is clear since permuting coordinates turns cubes into cubes of the same volume.
(4) This statement follows from the straightforward observation that any closed cube is contained in an open cube of at most twice the volume. ■



Lemma 30.5. Let $A \subset \mathbb{R}^n$ be a measure zero subset and let $f \colon A \to \mathbb{R}^n$ be a smooth map. Then $f(A)$ also has measure zero.

Remark. The conclusion of Lemma 30.5 does not hold if we replace "smooth" by "continuous":

(1) It is clear that $I = \{(x,0) \,|\, x \in [-1,1]\} \subset \mathbb{R}^2$ has measure zero, but in Theorem 6.13 we saw that there exists a space-filling curve, i.e. a map $I \to [0,1]^2$ that is surjective. But, as we will see in the Cubes-are-Not-Measure Zero Proposition 30.6, $[0,1]^2 \subset \mathbb{R}^2$ does not have measure zero.

(2) In Exercise 30.3 we will see that there exists a homeomorphism $[0,1] \to [0,2]$ and a measure zero subset $C \subset [0,1]$ such that $f(C)$ does not have measure zero.

Proof. Let $A \subset \mathbb{R}^n$ be a measure zero subset and let $f\colon A \to \mathbb{R}^n$ be a smooth map. We need to show that $f(A)$ also has measure zero. First let $P \in A$. By definition of a smooth map there exists an open neighborhood U_p and a smooth function $f\colon U_P \to \mathbb{R}^n$ which agrees with the original f on $A \cap U_P$. Next we pick $r > 0$ such that $V_P := \overline{B}^n_r(P) \subset U_P$. By the Second Countability Lemma 9.1 we know that A is second-countable. Thus it follows from the Countable Covering Lemma 9.2 that there exist countably many $P \in A$ such that A is covered by the V_P. Therefore, by the Measure Zero-Basics Lemma 30.4 it suffices to show that each $f(V_P \cap A)$ has measure zero.

So let $P \in A$, let $V_P = \overline{B}^n_r(P)$ and let $f\colon U_P \to \mathbb{R}^n$ be as above. Given a matrix $A \in \mathrm{M}(n \times n, \mathbb{R})$ we define its norm as

$$\|A\| \;:=\; \max\{\|Av\| \,|\, v \in S^{n-1}\} \;\in\; \mathbb{R}_{\geq 0}.$$

In Exercise 2.45 (h) we saw that the norm is a continuous map on $\mathrm{M}(n \times n, \mathbb{R})$. Thus, since V_P is compact, it follows that by the Compact Image Lemma 2.13 we can set

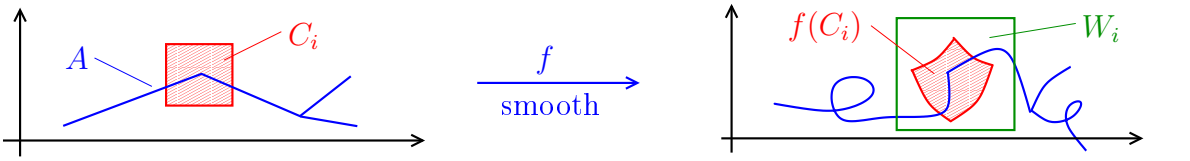
$$M \;:=\; \max\{\|\mathrm{D}f_P\| \,|\, P \in V_P\}.$$

Claim. For every $x, x' \in \overline{B}^n_r(P)$ we have

$$\|f(x) - f(x')| \;\leq\; M \cdot \|x - x'\|.$$

Proof. Let $x, x' \in \overline{B}^n_r(P)$. We set $v := x' - x$. We perform the following calculation:

$$\begin{array}{ccccccc}
 & \text{Fundamental Theorem of Calculus} & & \text{Chain Rule 19.10} & & \text{Integral Inequality Lemma 0.16} & \\
\|f(x) - f(x')\| & \overset{\downarrow}{=} & \left\| \int_{t=0}^{t=1} \frac{d}{dt} f(x+tv)\, dt \right\| & \overset{\downarrow}{=} & \left\| \int_{t=0}^{t=1} \mathrm{D}f_{x+tv} \cdot v\, dt \right\| & \overset{\downarrow}{\leq} & \int_{t=0}^{t=1} \|\mathrm{D}f_{x+tv} \cdot v\|\, dt \\
 & \leq & \int_{t=0}^{t=1} \|\mathrm{D}f_{x+tv}\| \cdot \|v\|\, dt & \leq & \int_{t=0}^{t=1} M \cdot \|v\|\, dt \;=\; M \cdot \|v\| \;=\; M \cdot \|x - x'\|. & & \\
 & \text{Exercise 2.45 (a)} & & \text{definition of } M & & & \boxplus
\end{array}$$



Let $\epsilon > 0$. We pick $\delta > 0$ with $\delta \cdot (2M)^n \leq \epsilon$. By the Measure Zero-Basics Lemma 30.4 (1) we know that $A \cap V_P$ is a subset of measure zero. Therefore there exists a countable set of closed cubes $\{C_i\}_{i \in \mathbb{N}}$ with $A \cap V_P \subset \bigcup_{i \in \mathbb{N}} C_i$ and with $\sum_{i \in \mathbb{N}} \mathrm{vol}(C_i) < \delta$. After possibly splitting each closed cube C_i into smaller closed cubes we can assume that each C_i is contained in

U_P.[311] It follows from the claim, together with an elementary geometric argument regarding diameters and cubes, that the image $f(C_i)$ of the cube C_i is contained in a cube W_i whose side length is $2M$-times larger than the side length of C_i. In other words, $f(C_i)$ is contained in a closed cube with $\mathrm{vol}(W_i) = (2M)^n \cdot \mathrm{vol}(C_i)$. We now see that

$$f(A \cap V_P) \subset f\Big(\bigcup_{i\in\mathbb{N}} C_i\Big) = \bigcup_{i\in\mathbb{N}} f(C_i) \subset \bigcup_{i\in\mathbb{N}} W_i.$$

The following calculation, together with the Measure Zero-Basics Lemma 30.4 (4), completes the proof:

$$\sum_{i=1}^{\infty} \mathrm{vol}(W_i) = \sum_{i=1}^{\infty} (2M)^n \cdot \mathrm{vol}(C_i) = (2M)^n \cdot \sum_{i=1}^{\infty} \mathrm{vol}(C_i) < (2M)^n \cdot \delta \leq \epsilon. \qquad \blacksquare$$

Now we can provide the proofs of Propositions 30.1 and 30.2.

Proof of the Measure Zero-via-Atlas Proposition 30.1. Let M be an m-dimensional smooth manifold ad let $X \subset M$ be a subset. Suppose that there exists a family of smooth charts $\{\Phi_i \colon U_i \to V_i\}_{i\in I}$ such that the following two conditions hold:

(1) for each $i \in I$ the set $\Phi_i(X \cap U_i)$ is a subset of measure zero of $\mathbb{R}^m$,

(2) we have $X \subset \bigcup_{i\in I} U_i$.

Note that it follows from the Second Countability Lemma 9.1 together with the Countable Covering Lemma 9.2 that X is already covered by countably many of the U_i. Thus we might as well assume that I is countable.

We need to show that X has measure zero. Thus let $\Psi \colon A \to B$ be a smooth chart. We need to show that $\Psi(A \cap X)$ has measure zero in $\mathbb{R}^m$. Note that

$$\Psi(A \cap X) = \Psi\Big(\bigcup_{i\in I}(U_i \cap X)\Big) = \Psi\Big(\bigcup_{i\in I}\Phi_i^{-1}(\Phi_i(U_i \cap X))\Big) = \bigcup_{i\in I} \underbrace{(\underbrace{\Psi \circ \Phi_i^{-1}}_{\text{smooth}})(\underbrace{\Phi_i(U_i \cap X)}_{\text{measure zero by (1)}})}_{\text{measure zero by Lemma 30.5}}$$

Since I is countable we now obtain from the Measure Zero-Basics Lemma 30.4 that $\Psi(A \cap X)$ does indeed have measure zero. $\blacksquare$

Proof of the Measure-Zero Properties Proposition 30.2. Let M be an m-dimensional smooth manifold.

(1) Let X be a subset of measure zero of M. It follows almost immediately from the Measure Zero-Basics Lemma 30.4 (1) that any subset of X also has measure zero.

[311] This can be seen as follows. Since U_P is open and since $V_P \subset U_P$ is compact we see that there exists an $\epsilon > 0$ such that every closed cube that intersects V_P and which has side length $< \epsilon$ is actually contained in U_P. Now let C be a cube of side length d. We pick $m \in \mathbb{N}$ such that $\frac{d}{m} < \epsilon$ and we break C into m^n closed cubes of side length $\frac{d}{m}$. Now we only take those cubes which have non-empty intersection with V_P.

(2) (a) It follows easily from the Measure Zero-Basics Lemma 30.4 (2) and the definitions that the union of countably many subsets of measure zero is again a subset of measure zero.
(b) It follows from (a) and de Morgan's Laws 0.1 that the intersection of countably many subsets of full measure is again a subset of full measure.

(3) (a) Let $f\colon M \to N$ be a smooth map between smooth manifolds of the same dimension and let X be a subset of measure zero in M. We need to show that $f(X)$ has measure zero in N. Let $\Psi\colon A \to B$ be a smooth chart for N. We need to show that $\Psi(A \cap f(X))$ has measure zero in $\mathbb{R}^n$. By the Countable Covering Lemma 9.2 we know that M admits a countable smooth atlas $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$. Now we see that

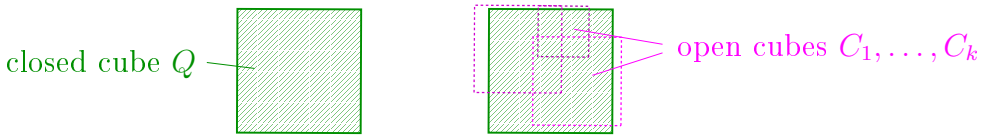
$$\begin{aligned}\Psi(A\cap f(X)) &= \Psi\Big(\bigcup_{i\in I} f\big(f^{-1}(A)\cap X\cap U_i\big)\Big) = \Psi\Big(\bigcup_{i\in I} f\big(\Phi_i^{-1}(\Phi_i(f^{-1}(A)\cap X\cap U_i))\big)\Big)\\ &= \underbrace{\bigcup_{i\in I} \underbrace{(\Psi\circ f\circ \Phi_i^{-1})}_{\text{smooth}}\underbrace{(\Phi_i(f^{-1}(A)\cap X\cap U_i))}_{\text{measure zero by (1)}}}_{\text{measure zero by Lemma 30.5}}\end{aligned}$$

It follows from the Measure Zero-Basics Lemma 30.4 (2) that $\Psi(A \cap f(X))$ does indeed have measure zero.
(b) This statement is an immediate consequence of (a).

(4) Let M and N be two smooth manifolds with $m := \dim(M) < \dim(N) =: n$. Furthermore let $f\colon M \to N$ be a smooth map. We need to show that $f(M)$ is a subset of measure zero in N. We consider the n-dimensional smooth manifold $W := M\times\mathbb{R}^{n-m}$.
It follows from $n - m > 0$ and the discussion on page 762 that $\{0\} \subset \mathbb{R}^{n-m}$ is a subset of measure zero. Using product charts and using the Measure Zero-via-Atlas Proposition 30.1 it follows easily that $M \times \{0\}$ is a subset of measure zero of $W = M \times \mathbb{R}^{n-m}$. Now consider the smooth map $g\colon W = M \times \mathbb{R}^{n-m} \to N$ that is given by $g(x, v) = f(x)$. Evidently $g(M \times \{0\}) = f(M)$. It follows from the above and (3a) that $g(M \times \{0\})$ has measure zero in N. ■

For the proof of the Full Measure-Density Proposition 30.3 we need the following subtle proposition.

Proposition 30.6. (Cubes-are-Not-Measure Zero Proposition) If Q is a closed cube with side length > 0, then Q does not have measure zero.



Proof. The statement of the proposition follows of course from standard theory of Lebesgue measures. In the following we give a self-contained proof which in [**GP1974**, p. 203] gets attributed to John von Neumann. Let Q be a closed cube with side length $q > 0$ in $\mathbb{R}^m$. Suppose that we have a countable covering $Q \subset \bigcup_{i\in I} C_i$ by open cubes. Given $i \in I$ we denote by c_i the side length of C_i. It suffices to prove the following claim.

Claim. We have the inequality $\sum_{i\in I} c_i^m \geq q^m$.

Proof. Since Q is compact we see that Q is covered by finitely many C_i. Thus we can assume that $I = \{1, \ldots, k\}$ and that $Q \subset C_1 \cup \cdots \cup C_k$. Given $n \in \mathbb{N}$ we set

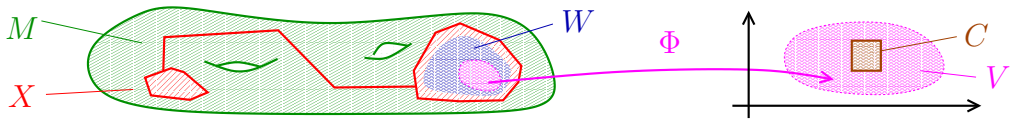
$$X_n := (\tfrac{1}{n}\cdot\mathbb{Z})^m = \{(r_1, \ldots, r_m) \,|\, r_1, \ldots, r_m \in \tfrac{1}{n}\mathbb{Z}\}.$$

We make the following crucial observation: Given any cube $D \subset \mathbb{R}^m$, closed or open, of

side length d we have[312]

$$(*) \qquad \lceil d \cdot n \rceil^m \;\geq\; \#(D \cap X_n) \;\geq\; \lfloor d \cdot n \rfloor^m.$$

Now we see that



$$\sum_{i=1}^{k} \lceil c_i \cdot n \rceil^m \;\underset{\text{by } (*)}{\geq}\; \sum_{i=1}^{k} \#(X_n \cap C_i) \;\geq\; \#\Big(X_n \cap \bigcup_{i=1}^{k} C_i\Big) \;\underset{\text{since } Q \subset C_1 \cup \cdots \cup C_k}{\geq}\; \#(X_n \cap Q) \;\underset{\text{by } (*)}{\geq}\; \lfloor r \cdot n \rfloor^m.$$

Using the inequalities $x + 1 \geq \lceil x \rceil$ and $\lfloor x \rfloor \geq x - 1$ we see that

$$\sum_{i=1}^{k} (c_i \cdot n + 1)^m \;\geq\; (r \cdot n - 1)^m.$$

If we now divide both sides by n^m and if we take the limit $n \to \infty$, then we obtain the promised inequality $\sum_{i=1}^{k} c_i^m \geq q^m$. ■

Proof of the Full Measure-Density Proposition 30.3. Let M be an m-dimensional smooth manifold and let X be a subset. We will show that if $M \setminus X$ is not dense, then X cannot have measure zero. If $M \setminus X$ is not dense, then there exists an open non-empty subset W of M which has empty intersection with $M \setminus X$. In other words, $W \subset X$. Now let $\Phi\colon U \to V$ be a smooth chart with $U \subset W$. Since $V = \Phi(U)$ is an open non-empty subset of $\mathbb{R}^m$ it contains a closed cube C with side length > 0. It follows from the Cubes-are-Not-Measure Zero Proposition 30.6 that $V = \Phi(U)$ is not a subset of measure zero. Since $V = \Phi(U) \subset W \subset X$ we obtain from the Measure Zero-Basics Lemma 30.4 that X is not a subset of measure zero. ■

30.3. **The Weak Whitney Embedding Theorem.** In the Euclidean Embedding Theorem 27.1 we saw that every smooth manifold M can be properly smoothly embedded into some $\mathbb{R}^n$. For compact manifolds the following proposition nails down n in terms of the dimension of M.

Theorem 30.7. (Weak Whitney Embedding Theorem) Every m-dimensional smooth manifold M admits a smooth embedding $f\colon M \to \mathbb{R}^{2m+1}$ such that $f(M)$ is a closed subset of $\mathbb{R}^{2m+1}$.

[312] This observation follows from the fact that given any interval $I \subset \mathbb{R}$ of length d we have

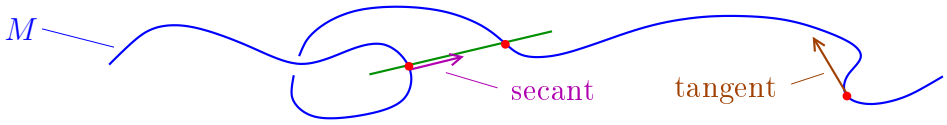
$$\lceil d \cdot n \rceil \;\geq\; \#\big(I \cap \{x \in \tfrac{1}{n} \cdot \mathbb{Z}\}\big) \;\geq\; \lfloor d \cdot n \rfloor.$$

Remark.

(1) In the Covering Dimension-of-Manifolds Proposition 27.7 we showed that the covering dimension of an m-dimensional topological manifold M is $\leq m$. As we already mentioned on page 727 it follows almost immediately from the Euclidean Embedding Theorem 11.13 for Topological Spaces that there exists a closed embedding $M \to \mathbb{R}^{2m+1}$. The Weak Whitney Embedding Theorem 30.7 betters the result in the sense that for smooth manifolds it provides a smooth embedding into $\mathbb{R}^{2m+1}$.

(2) The fact that the dimension $2m+1$ appears in the Euclidean Embedding Theorem 11.13 for Topological Spaces and the Weak Whitney Embedding Theorem 30.7 suggests that it is a dimension barrier that is hard to break. In fact the Strong Whitney Embedding Theorem **??**, which is significantly harder to prove, shows that for smooth manifolds we can improve the dimension by 1, namely it says that any m-dimensional smooth manifold admits a smooth embedding into $\mathbb{R}^{2m}$.

(3) Later on we will prove some negative results, for example in Propositions 123.11 and the Topological Codimension-One Orientability Proposition 124.5 we will see that the real projective space $\mathbb{R}\mathrm{P}^n$ does not admit a smooth embedding into $\mathbb{R}^{n+1}$.



The proof of the Weak Whitney Embedding Theorem 30.7 requires the following lemma, which is perhaps of interest in its own right.

Lemma 30.8. Let M be an m-dimensional smooth submanifold of $\mathbb{R}^n$. We consider the vectors $v \in S^{n-1}$ with the following two properties:

(1) v does *not* lie in any tangent space $\widetilde{\mathrm{T}}_P M$.

(2) v is *not* secant to M, in other words, for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to v.

If $n > 2m+1$ the set of such vectors is dense in S^{n-1}.

Proof of Lemma 30.8. Let M be an m-dimensional submanifold of $\mathbb{R}^n$. We start out with the following claim.

Claim. The subsets[313]

$$\begin{array}{lrcll} (1) & X & := & \{(P,w) \,|\, P \in M, w \in \widetilde{\mathrm{T}}_P M \setminus \{0\}\} & \subset \mathbb{R}^n \times \mathbb{R}^n \\ (2a) & Y_a & := & \{(x,y) \in M \times (M \setminus \partial M) \,|\, x \neq y\} & \subset \mathbb{R}^n \times \mathbb{R}^n \\ (2b) & Y_b & := & \{(x,y) \in M \times \partial M \,|\, x \neq y\} & \subset \mathbb{R}^n \times \mathbb{R}^n \end{array}$$

are smooth submanifolds of $\mathbb{R}^n \times \mathbb{R}^n$ of dimension $\leq 2m$.

Proof. First we consider X. Thus let $(P,w) \in X$. We pick a submanifold chart $\Phi\colon U \to V$ around $P \in M$. The map

$$\begin{array}{rcl} \Psi\colon U \times (\mathbb{R}^n \setminus \{0\}) & \to & V \times (\mathbb{R}^n \setminus \{0\}) \\ (x,v) & \mapsto & (\Phi(x), \mathrm{D}\Phi_x(v)) \end{array}$$

[313] This claim is closely related to Exercises 19.29 and 19.30.

is easily seen to be smooth and, using Φ^{-1}, one can easily write down a smooth inverse. Thus we see that Ψ is a diffeomorphism. Up to a permutation of coordinates the map Ψ is a $2m$-dimensional smooth submanifold chart for $(P, w) \in X$.

Now we turn to Y_a and Y_b. Using products of submanifold charts one can easily show that the product of two smooth submanifolds of $\mathbb{R}^n$, where at most one has non-empty boundary, is a smooth submanifold of $\mathbb{R}^n \times \mathbb{R}^n$ of the obvious dimension. The subsets Y_a and Y_b are open subsets of such products, thus they are smooth submanifolds with $\dim(Y_a) = 2m$ and $\dim(Y_b) = 2m - 1$. ⊞

In the following we suppose that $n > 2m + 1$. We consider the maps[314]

$$\begin{array}{rrcl} f\colon X = \{(P,w) \,|\, P \in M, w \in \widetilde{\mathrm{T}}_P M \setminus \{0\}\} & \to & \mathbb{R}\mathrm{P}^{n-1} = (\mathbb{R}^n \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \\ (P,w) & \mapsto & [w] \\ \text{and} \quad g_a\colon Y_a = \{(x,y) \in M \times (M \setminus \partial M) \,|\, x \neq y\} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ (x,y) & \mapsto & [x-y] \\ g_b\colon Y_b = \{(x,y) \in M \times \partial M \,|\, x \neq y\} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ (x,y) & \mapsto & [x-y]. \end{array}$$

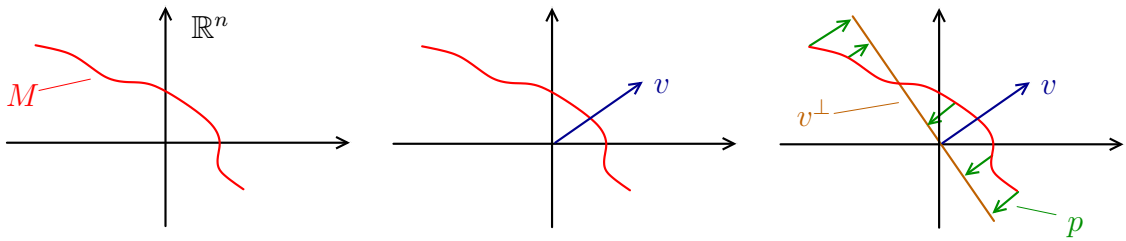
On page 564 we equipped $\mathbb{R}\mathrm{P}^{n-1}$ with a standard smooth structure and thus we can view $\mathbb{R}\mathrm{P}^{n-1}$ as an $(n-1)$-dimensional smooth manifold. As we just showed in the claim, the domains X, Y_a and Y_b of the above maps are smooth submanifolds of $\mathbb{R}^{2n} = \mathbb{R}^n \times \mathbb{R}^n$ of dimension $\leq 2m$. It follows from the discussion on page 564 that the maps f, g_a and g_b are smooth. Since $2m < n-1$ we obtain from Proposition 30.3 together with the Measure-Zero Properties Proposition 30.2 (2) that the complement of the union of the images of f, g_a and g_b is dense.

Let $p\colon S^{n-1} \to \mathbb{R}\mathrm{P}^{n-1}$ be the projection . One can easily show, see Exercise 5.31, that the preimage of a dense subset of $\mathbb{R}\mathrm{P}^{n-1}$ is a dense subset of S^{n-1}. The lemma now follows from the above discussion and the observation that we have the following equality:

$$\begin{array}{c}\text{set of vectors in } \mathbb{R}^n \setminus \{0\} \\ \text{that satisfy (1) and (2)}\end{array} = p^{-1}(\text{complement of the images of } f, g_a \text{ and } g_b).$$ ■

Now we turn to the proof of the Weak Whitney Embedding Theorem 30.7. As always, the case that M is compact is easier, so let us treat it first.

Proof of the Weak Whitney Embedding Theorem 30.7 if M is compact. Let M be an m-dimensional smooth manifold. We claim that we can smoothly embed M into $\mathbb{R}^{2m+1}$. By the Euclidean Embedding Theorem 27.1 together with the Smooth Embedding Theorem 24.10 we can assume that M is already a submanifold of some $\mathbb{R}^n$. If $n \leq 2m+1$ there is nothing to prove, so we may assume that $n > 2m+1$. By Lemma 30.8 there exists a non-zero vector $v \in \mathbb{R}^n$ which does not lie in any tangent space $\widetilde{\mathrm{T}}_P M$ and that is not secant to M, in other words, for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to v.



We consider the projection of $\mathbb{R}^n$ onto the orthogonal complement of v, i.e. we consider the projection

$$\begin{array}{rcl} p\colon \mathbb{R}^n & \to & v^\perp = \{w \in \mathbb{R}^n \,|\, \langle w, v\rangle = 0\} \\ u & \mapsto & u - \langle u, v\rangle \cdot \frac{v}{\|v\|^2}. \end{array}$$

[314] Here we use the identification $\mathbb{R}^n \setminus \{0\})/(\mathbb{R} \setminus \{0\}) = \mathbb{R}\mathrm{P}^{n-1} := S^{n-1}/\{\pm 1\}$ from page 255.

Since v does not lie in any tangent space $\widetilde{\mathrm{T}}_P M$ we see that $p\colon M \to v^\perp$ is an immersion. Furthermore, since v is not secant to M we see that $p\colon M \to v^\perp$ is injective. Since we assume that M is compact we obtain from the Compact-Hausdorff Proposition 2.17 (3) that $p\colon M \to v^\perp$ is actually an embedding.

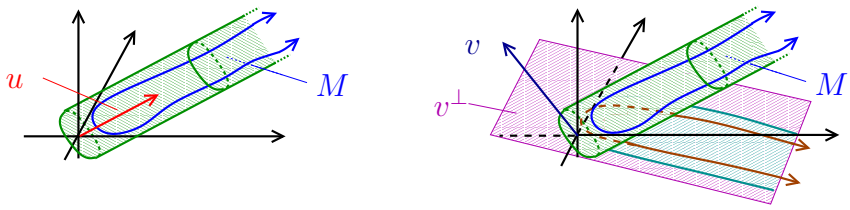
In summary we have shown that the restriction of the projection p to M is a smooth embedding. Thus we have embedded M into a real vector space of dimension $n-1$. Iterating this process we get a smooth embedding of M into $\mathbb{R}^{2m+1}$. ■

Evidently we also want to prove the Weak Whitney Embedding Theorem 30.7 for possibly non-compact smooth manifolds. As an example, let us consider $\mathbb{Z}^2 \subset \mathbb{R}^2$. This is a non-compact 0-dimensional proper smooth submanifold of $\mathbb{R}^2$. Lemma 30.8 shows that there exist (many) vectors $v \in S^1$ such that the projection of $\mathbb{Z}^2$ onto $v^\perp$ is injective. But, as we will see in Exercise 30.6, none of these projections will be an embedding, i.e. a homeomorphism onto its image. Thus, to deal with non-compact smooth manifolds we will have to come up with a new idea.

We will need the following elementary lemma, which is the content of Exercise 28.8.

Lemma 30.9. Given any m-dimensional smooth manifold M there exists an m-dimensional smooth manifold N with $\partial N = \varnothing$ and a smooth embedding $\varphi\colon M \to N$ such that $\varphi(M)$ is a closed subset of N.

Proof. Let M be an m-dimensional smooth manifold. By the Smooth Collar Neighborhood Theorem 28.3 we can pick a collar neighborhood $[0,1] \times \partial M$. Using the Smooth Transition Function Lemma 19.4 one can show easily that there exists a diffeomorphism $f\colon [0,1] \to [\frac{1}{4}, 1]$ such that $\varphi(t) = t$ for $t \in [\frac{1}{2}, 1]$. It is now straightforward to verify that the map



$$\begin{array}{rcl} \varphi\colon M & \to & N := M \setminus \partial M \\ x & \mapsto & \begin{cases} x, & \text{if } x \notin [0,1] \times \partial M, \\ (\varphi(t), y), & \text{if } x = (t,y) \in [0,1] \times \partial M \end{cases} \end{array}$$

is a smooth embedding such that the image is a closed subset of N. ■

Proof of the Weak Whitney Embedding Theorem 30.7 if M is non-compact. Let M be an m-dimensional smooth manifold. We need to show that there exists a smooth embedding $f\colon M \to \mathbb{R}^{2m+1}$ such that $f(M)$ is a closed subset of $\mathbb{R}^{2m+1}$. It follows from Lemma 30.9 that we might as well assume that $\partial M = \varnothing$.

Given $N \in \mathbb{N}$ we say that M *is N-tubular* if there exists a $u \in \mathbb{R}^N$, an $r > 0$ and a proper smooth embedding of M into

$$T(u,r) \;:=\; \{\mu \cdot u + w \,|\, \mu \in \mathbb{R}_{\geq 0}, \text{ and } w \in u^\perp \text{ with } \|w\| \leq r\}.$$

Note that if M is N-tubular, then it follows from the Euclidean Embedding Theorem 27.1 that M is indeed diffeomorphic to a proper submanifold of $\mathbb{R}^N$. Thus it remains to show that M is $(2m+1)$-tubular. We start out with the following claim.

Claim 1. The smooth manifold M is tubular for some $N \in \mathbb{N}$.

Proof. By the Euclidean Embedding Theorem 27.1 there exists a smooth embedding $f\colon M \to \mathbb{R}^k$ for some $k \in \mathbb{N}$. On page 537 we gave an explicit diffeomorphism $\alpha\colon \mathbb{R}^k \to B^k$. By the Manifold Exhaustion Lemma 21.2 we know that there exists a smooth exhaustion function $\varphi\colon M \to \mathbb{R}_{\geq 0}$, in other words, there exists a smooth map $\varphi\colon M \to \mathbb{R}_{\geq 0}$ such that the preimage of each compact interval $[0,c]$ is compact. Next we consider the map

$$\begin{array}{rcl} \Theta\colon M & \to & \mathbb{R} \times \mathbb{R}^k = \mathbb{R}^{k+1} \\ x & \mapsto & (\varphi(x), (\alpha \circ f)(x)). \end{array}$$

Note that $\Theta(M) \subset T(e_1, 1)$. Finally note that it follows from Lemma 27.9 that Θ is a proper smooth embedding. ⊞

We see that it remains to prove the following claim.

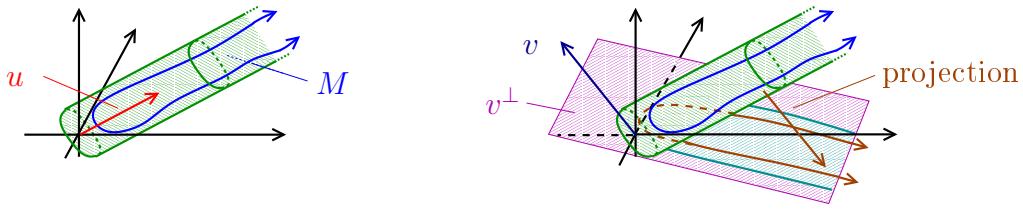
Claim 2. If M is N-tubular for some $N > 2m+1$, then M is also $(N-1)$-tubular.

Proof. We can assume that there exists a $u \in \mathbb{R}^N$ and an $r > 0$ such that M is a proper submanifold of $T(u,r) \subset \mathbb{R}^N$. By Lemma 30.8 there exists a $v \in \mathbb{R}^N$ with $v \notin \mathbb{R} \cdot u$ with the following two properties:

(1) v does *not* lie in any tangent space $\widetilde{\mathrm{T}}_P M$.
(2) v is *not* secant to M.

It follows from elementary linear algebra that there exists an isometry $\Theta\colon v^\perp \to \mathbb{R}^{N-1}$ of Euclidean real vector spaces. As on page 770 we consider the map

$$\begin{array}{rcl} p\colon \mathbb{R}^N & \to & v^\perp \\ x & \mapsto & x - \langle x, v\rangle \cdot \frac{v}{\|v\|^2} \end{array}$$



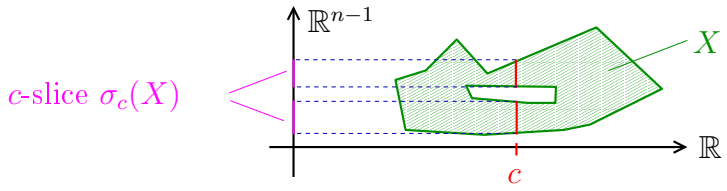
and now we also consider

$$\begin{array}{rcl} \Phi\colon \mathbb{R}^N & \to & \mathbb{R}^{N-1} \\ x & \mapsto & \Theta(p(v)). \end{array}$$

It follows easily from the fact that Θ is an isometry that $\Phi(T(v,r)) \subset T(\Phi(v), r)$. Thus it remains to show that $\Phi\colon M \to \mathbb{R}^{N-1}$ is a proper smooth embedding. Since v does not lie in any tangent space $\widetilde{\mathrm{T}}_P M$ we see, similar to the discussion on page 770, that $\Phi\colon M \to v^\perp$ is an immersion and we see, using that v is not secant to M, that $\Phi\colon M \to v^\perp$ is injective. By the Proper-Closed Proposition 2.43 and Lemma 2.44 (1) it remains to show that the preimage of each compact ball $\overline{B}_s^{N-1}(0)$ under the map $\Phi\colon M \to \mathbb{R}^{N-1}$ is compact. Thus let $s \geq 0$. Note that for each $x = \mu \cdot u + w \in T(u,r)$ with $w \in u^\perp$ and $\|w\| \leq r$ we have

$$\|\Phi(x)\| \underset{\substack{\uparrow \\ \text{since } \Phi \text{ is} \\ \text{an isometry}}}{=} \|p(x)\| \underset{\substack{\uparrow \\ \text{since } p \text{ is linear and} \\ \text{by the triangle inequality}}}{\geq} \|p(\mu \cdot u)\| - \|p(w)\| \underset{\substack{\uparrow \\ \text{since } p \text{ is linear and since } \|w\| \leq r}}{\geq} |\mu| \cdot \|p(u)\| - \max\big\{\|p(w)\| \,\big|\, w \in \overline{B}_r^N\big\}.$$

Recall that we cleverly picked $v \notin \mathbb{R} \cdot u$. Thus we see that $\|p(u)\| > 0$. It follows easily from this discussion that $\Phi^{-1}(\overline{B}_s^{N-1}(0)) \cap T(u,r)$ is bounded. Since $M \subset T(u,r)$ is closed we see that $\Phi^{-1}(\overline{B}_r^{N-1}(0))$ is a compact subset of M. ■



30.4. **The Mini-Fubini Theorem.** We conclude this chapter on subsets of measure zero with the "Mini-Fubini Theorem" which will play an important role in the proof of Sard's Theorem 31.1 in the next chapter. Our Mini-Fubini Theorem is a basic version of the Fubini Theorem [**StS2005**, Chapter 2.3.1] from measure and integration theory. To formulate the result we need to introduce the following harmless definition.

Notation. Let $X \subset \mathbb{R}^n$ be a subset. Given $c \in \mathbb{R}$ we refer to

$$\sigma_c(X) \;:=\; \{y \in \mathbb{R}^{n-1} \,|\, (c,y) \in X\}.$$

as the c-slice of X.

Now we can formulate the lemma which we will use in the proof of Sard's Theorem 31.1.

Lemma 30.10. (Mini-Fubini) Let $X \subset \mathbb{R}^n$ be a compact subset such that each slice $\sigma_c(X)$ is of measure zero in $\mathbb{R}^{n-1}$. Then X has measure zero in $\mathbb{R}^n$.

Remark. Lemma 30.10 follows from the Fubini Theorem in measure theory. But as we will see, one can also give a completely elementary proof, thus there is no need to cite high-powered results.

Proof. Given $U \subset \mathbb{R}^m$ we set

$$\mathrm{vol}_m(U) \;:=\; \inf\left\{ \sum_{i\in I} \mathrm{vol}(C_i) \;\middle|\; \begin{array}{c} \{C_i\}_{i\in I} \text{ is a countable} \\ \text{family of open cubes with } U \subset \bigcup_{i\in I} C_i \end{array} \right\} \;\in\; \mathbb{R}_{\geq 0} \cup \{\infty\}.$$

Claim 1. The following statements hold:

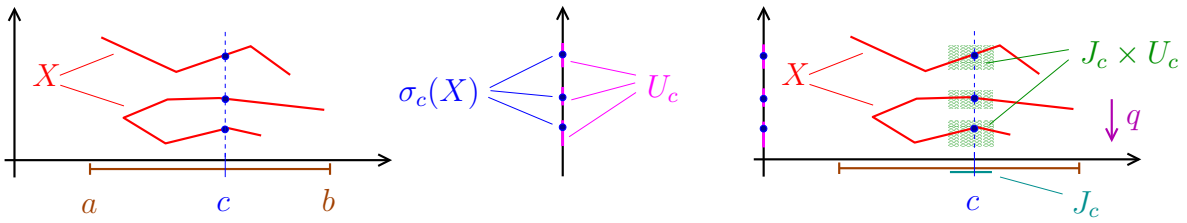
(i) A subset $U \subset \mathbb{R}^m$ has measure zero if and only if for every $\epsilon > 0$ we have $\mathrm{vol}_m(U) \leq \epsilon$.
(ii) Given $U \subset V \subset \mathbb{R}^m$ we have $\mathrm{vol}_m(U) \leq \mathrm{vol}_m(V)$.
(iii) For every interval (c,d) and every subset U of $\mathbb{R}^{m-1}$ we have

$$\mathrm{vol}_m((c,d) \times U) \;\leq\; (d-c) \cdot \mathrm{vol}_{m-1}(U).$$

(iv) For $U_1, \ldots, U_l \subset \mathbb{R}^m$ we have $\mathrm{vol}_m(U_1 \cup \cdots \cup U_l) \leq \mathrm{vol}_m(U_1) + \cdots + \mathrm{vol}_m(U_l)$.

Proof. Statements (i), (ii) and (iv) are very elementary. The only proof which is not a one-liner is the proof of (iii). We leave it to the reader to provide the proofs. ⊞

Now we start with the actual proof of the lemma. Thus let $X \subset \mathbb{R}^n$ be a compact subset such that each slice $\sigma_c(X)$ is of measure zero in $\mathbb{R}^{n-1}$. We need to show that X has measure zero in $\mathbb{R}^n$. Since X is compact there exist $a, b \in \mathbb{R}$ with $X \subset [a,b] \times \mathbb{R}^{n-1}$. We fix some $\delta > 0$. Next let $c \in [a,b]$. By hypothesis we know that $\sigma_c(X) \subset \mathbb{R}^{n-1}$ has measure zero. By (i) there exists an open set $U_c \subset \mathbb{R}^{n-1}$, given as the countable union of open cubes, with $\sigma_c(X) \subset U_c$ and $\mathrm{vol}_{n-1}(U_c) \leq \delta$.



Claim 2. There exists an open interval J_c with $c \in J_c$ and with $X \cap (J_c \times \mathbb{R}^{n-1}) \subset J_c \times U_c$.

Proof. We consider $K := X \setminus (\mathbb{R} \times U_c)$. Since U_c is open we see that K is a closed subset of X, hence it follows from the Compact-Closed Lemma 1.21 that K is also compact. Next consider the map $q\colon K \to \mathbb{R}$ that is given by projection onto the first coordinate. By construction $c \notin q(K)$. Since K is compact we know by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 (2) that $\mathbb{R} \setminus q(K)$ is open. This implies that there exists an open interval J_c that contains c and with $J_c \subset \mathbb{R} \setminus q(K)$. This open interval has the desired properties. ⊞

We have thus shown that for each $c \in [a,b]$ there exists an open subset $U_c \subset \mathbb{R}^{n-1}$ with $\mathrm{vol}_{n-1}(U_c) < \delta$ and an open interval J_c with $X \cap (J_c \times \mathbb{R}^{n-1}) \subset J_c \times U_c$. Since $[a,b]$ is compact we see that there exist $c_1, \ldots, c_l \in [a,b]$ such that $[a,b] \subset J_{c_1} \cup \cdots \cup J_{c_l}$. We write the intervals $J_{c_i} = (\alpha_i, \beta_i)$. An elementary argument[315] shows that after possibly shrinking the intervals we can arrange that $\sum_{i=1}^{l} (\beta_i - \alpha_i) \leq 2 \cdot (b-a)$. Altogether we see that

$$\mathrm{vol}_n(X) \underset{\text{by Claim 1 (ii)}}{\leq} \mathrm{vol}_n\Big(\bigcup_{i=1}^{l} J_{c_i} \times U_{c_i}\Big) \underset{\text{by Claim 1 (iv)}}{\leq} \sum_{i=1}^{l} \mathrm{vol}_n(J_{c_i} \times U_{c_i}) \underset{\text{by Claim 1 (iii)}}{\leq} \sum_{i=1}^{l} (\beta_i - \alpha_i) \cdot \underbrace{\mathrm{vol}_{n-1}(U_{c_i})}_{\leq \delta} \leq \delta \cdot 2 \cdot (b-a).$$

Since this inequality holds for every $\delta > 0$ we are done by Claim 1 (i). ■

On a later occasion we will also make use of the following converse to the Mini-Fubini Lemma 30.10.

Lemma 30.11. (Mini-Fubini II) Let $X \subset \mathbb{R}^n$ be a compact subset. If X has measure zero, then the set

$$\{c \in \mathbb{R}^{n-1} \mid \text{the } c\text{-slice } \sigma_c(X) \text{ has measure zero}\}$$

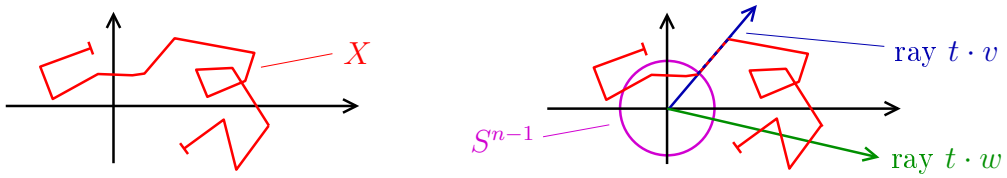
has full measure.

[315] For example one can arrange that for $i \in \{1, \ldots, l-1\}$ we have $\beta_i > \alpha_{i+1}$. Now one can easily modify the intervals by going "from left to right".

Proof. We will not provide a proof, we just point out that it follows from the usual Fubini Theorem in measure theory, see e.g. [**StS2005**, Chapter 2.3.1]. At least for $n = 2$ an elementary proof is given in [**Ox1971**, p. 51].[316] ■

Exercises for Chapter 30.

Exercise 30.1. Let $C \subset \mathbb{R}$ be the Cantor set as defined on page 130. Show that the Cantor set has measure zero.
Remark In Exercise 2.17 we saw that the Cantor set is uncountable. Thus we have shown that $\mathbb{R}$ contains uncountable subsets of measure zero.



Exercise 30.2. Let $X \subset \mathbb{R}^n$ be a subset. Given $v \in S^{n-1}$ we write

$$\mu_v(X) \;:=\; \{t \in \mathbb{R}_{\geq 0} \,|\, t \cdot v \in X\}$$

Show that if X is compact with measure zero, then

$$\{v \in S^{n-1} \,|\, \mu_v(X) \text{ has measure zero}\} \;\subset\; S^{n-1}$$

has full measure in S^{n-1}.
Hint. Use the Mini-Fubini Lemma 30.11 and the Measure-Zero Properties Proposition 30.2 (3b).

Exercise 30.3. Let $c\colon [0,1] \to [0,1]$ be the Cantor function that we introduced on page 185. We consider the map

$$\begin{array}{rccc} f\colon & [0,1] & \to & [0,2] \\ & x & \mapsto & x + c(x). \end{array}$$

(a) Show that f is a homeomorphism.
(b) Let $C \subset [0,1]$ be the Cantor set. Show that $f(C)$ has Lebesgue measure one, in particular it is not a subset of measure zero.
Hint. Determine the Lebesgue measure of $f([0,1] \setminus C)$.

Remark. In principle this exercise requires familiarity with the Lebesgue measure. But one can also get joy out of the exercise by using a "naive" approach to length.

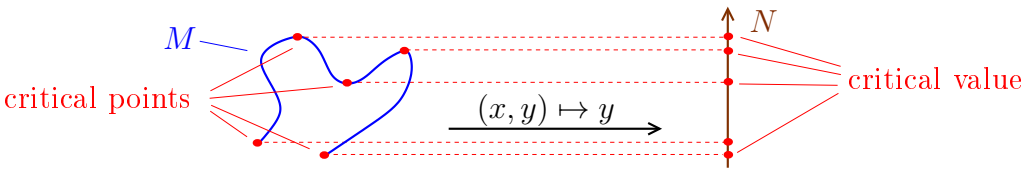
Exercise 30.4. Let $A \subset \mathbb{R}^n$ be a subset of diameter d.

(a) Does there exist a closed ball of radius $\frac{d}{2}$ that contains A?
(b) Does there exist a closed cube of side length d that contains A?

Exercise 30.5. Let M be an m-dimensional smooth manifold. Show that there exists an immersion $M \to \mathbb{R}^{2m}$.
Hint. Modify the proof of the Weak Whitney Embedding Theorem 30.7.

[316] The reader who has a self-contained proof of this lemma should communicate this proof to the author.

Exercise 30.6. We consider the non-compact 0-dimensional proper smooth submanifold $\mathbb{Z}^2 \subset \mathbb{R}^2$. Show that there is no $v \in S^1$ such that the projection of $\mathbb{Z}^2$ onto $v^\perp$ is a homeomorphism onto its image.

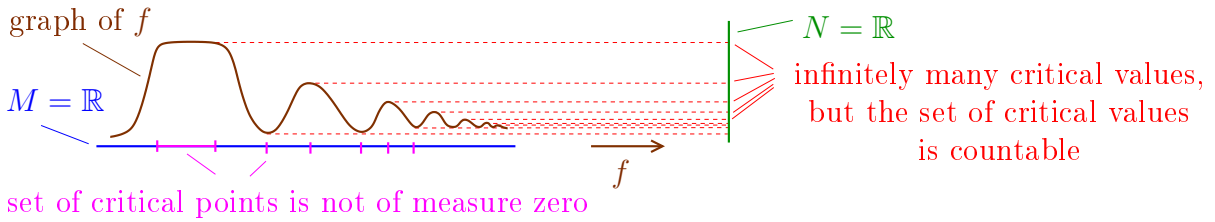


31. Sard's Theorem

We recall the following definition from page 701.

Definition. Let M and N be smooth manifolds and let $f\colon M \to N$ be a smooth map.

(1) Let $P \in M$.
   (a) If $P \in M \setminus \partial M$, then we say P is a regular point if $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is an epimorphism.
   (b) If $P \in \partial M$, then we say P is a regular point if $\mathrm{D}f_P\colon \mathrm{T}_P(\partial M) \to \mathrm{T}_{f(P)}N$ is an epimorphism.
   Otherwise we say that P is a critical point.



(2) We say $Q \in N$ is a regular value if all points in the preimage $f^{-1}(Q)$ are regular. Otherwise we call Q a critical value.

In this chapter we will prove Sard's Theorem 31.1 which says that for a smooth map $f\colon M \to N$ between smooth manifolds "almost every" point in N is a regular value. Sard's Theorem 31.1 is an absolutely essential tool in differential topology. As an amuse-bouche we will use it in this chapter to provide a proof of the Brouwer Fixed Point Theorem 31.4.

31.1. Sard's Theorem.

Theorem 31.1. (Sard's Theorem) If $f\colon M \to N$ is a smooth map between smooth manifolds (possibly with boundary)[317], then the set of critical values of f is of measure zero in N.

Remark.

(1) The theorem is named after Arthur Sard [**Sar1942**] who first proved a similar statement in 1942.

(2) As we pointed out on page 701, if $f\colon M \to N$ is a smooth map between smooth manifolds with $\dim(M) < \dim(N)$, then a point $Q \in N$ is a regular value if and only if $f^{-1}(Q) = \varnothing$. It follows from this observation that Sard's Theorem 31.1, together with the Measure-Zero Properties Proposition 30.2 (2), implies the Measure-Zero Properties Proposition 30.2 (4).

[317] We stress that M and N are allowed to have boundary, since (a) we need these cases, and (b) since many proofs in the literature assume that M and N do not have boundary.

(3) Sometimes Sard's Theorem 31.1 is also called *Morse-Sard Theorem*, since the case that $N = \mathbb{R}$ was first proved by Anthony Morse [**MorsA1939**] in 1939. Furthermore the fact that the set of regular values is dense was first proved by Arthur Brown [**BrownA1935**] in 1935.

The proof of Sard's Theorem 31.1 will be the content of the remainder of this section. Like many other textbooks we follow the account given in [**Miln1965a**, Chapter 3].

Proof. Let $f\colon M \to N$ be a smooth map between smooth manifolds. We need to show that the set of critical values of f is of measure zero in N. We set $m := \dim(M)$ and $n := \dim(N)$. We prove the theorem by induction on $m = \dim(M)$.

First let us consider the case $m = 0$. Note that this means that M is equipped with the discrete topology. Since smooth manifolds are in particular second-countable we see that M is a countable set. Thus the statement follows from the Measure-Zero Properties Proposition 30.2 (2).

Now assume that the conclusion of Sard's Theorem holds for smooth maps $M \to N$ with $\dim(M) < m$. Our goal is to prove Sard's Theorem for m-dimensional smooth manifolds M. From the observation that any smooth manifold is covered by a countable smooth atlas and from the definition of a smooth map on an open subset of $\mathbb{H}^m$ it follows easily, using the Measure-Zero Properties Proposition 30.2, that it suffices to deal with the case that M is an open subset of $\mathbb{R}^m$ and that $N = \mathbb{R}^n$. We denote by $f_1, \dots, f_n$ the coordinate functions of $f\colon M \to \mathbb{R}^n$.

We denote by $C \subset M \subset \mathbb{R}^m$ the set of critical points of $f\colon M \to N$. Given $k \in \mathbb{N}$ we set

$$C_k := \left\{ x \in C \;\middle|\; \begin{array}{c} \text{for all } j = 1, \dots, n \text{ and all } i = 1, \dots, k \text{ every} \\ \text{partial derivative of } f_j \text{ of order } i \text{ at } x \text{ vanishes} \end{array} \right\}.$$

Since f is smooth we know that all partial derivatives are continuous. Thus we see that C and all C_k's are closed in M. The proof of Sard's Theorem now proceeds in four steps.

Step 1. *The set $f(C \setminus C_1) \subset \mathbb{R}^n$ has measure zero.*
Let $a \in C \setminus C_1$. By definition of C_1 we know that there exists a $j \in \{1, \dots, n\}$ an $i \in \{1, \dots, k\}$ such that the partial derivative $\frac{\partial f_j}{\partial x_i}$ is non-zero at a. To simplify the notation we assume that $i = j = 1$. We write $\mathbb{R}^m = \mathbb{R} \times \mathbb{R}^{m-1}$ and we consider the map

$$\begin{array}{rcl} \Theta\colon M & \to & \mathbb{R}^m = \mathbb{R} \times \mathbb{R}^{m-1} \\ (\underbrace{x}_{\in \mathbb{R}}, \underbrace{y}_{\in \mathbb{R}^{m-1}}) & \mapsto & (f_1(x,y), y). \end{array}$$

Note that $\det(\mathrm{D}\Phi_a) = \frac{\partial f_1}{\partial x_1}(a) \neq 0$. Thus it follows from the Inverse Function Theorem 19.12 that Θ is a local diffeomorphism at a. This means that there exists an open neighborhood V_a of a in the open subset $M \setminus C_1$ such that $\Theta(V_a)$ is an open subset of $\mathbb{R}^m$ and such that $\Theta\colon V_a \to \Theta(V_a)$ is a diffeomorphism. By an elementary argument, similar to Lemma 19.16, we see that $f \circ \Theta^{-1}$ is of the form

$$(*) \qquad (f \circ \Theta^{-1})(x,y) = (x, \underbrace{g(x,y)}_{\in \mathbb{R}^{n-1}}) \qquad \text{for every } (x,y) \in \Theta(V_a)$$

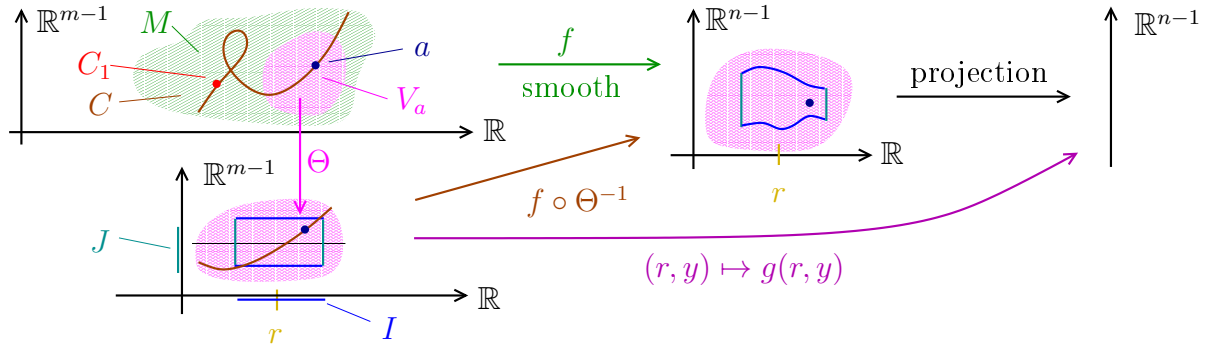
where $g\colon \Theta(V_a) \to \mathbb{R}^{n-1}$ is a smooth map. Next we pick a closed interval $I \subset \mathbb{R}$ and a closed ball $J \subset \mathbb{R}^{m-1}$, each with non-empty interior, such that $\Theta(a) \in I \times J \subset \Theta(V_a)$.

Claim. For each $r \in I$ we have

$$\begin{array}{l} r\text{-slice of the set of critical values} \\ \text{of the map } f \circ \Theta^{-1} \colon I \times J \to \mathbb{R} \times \mathbb{R}^{n-1} \end{array} \quad = \quad \text{set of critical values of } \begin{array}{rcl} \varphi_r \colon J & \to & \mathbb{R}^{n-1} \\ y & \mapsto & g(r,y). \end{array}$$

Proof. Let $r \in I$. Given $y \in J$ it follows from $(*)$ that we have the following equality:

$$\mathrm{D}(f \circ \Theta^{-1})_{(r,y)} \;=\; \begin{pmatrix} 1 & 0 \\ * & \mathrm{D}(y \mapsto g(r,y))_y \end{pmatrix} \;=\; \begin{pmatrix} 1 & 0 \\ * & \mathrm{D}(\varphi_r)_y \end{pmatrix}.$$



This shows that (r,y) is a critical point of $f \circ \Theta^{-1}$ if and only if y is a critical point of the map $\varphi_r \colon J \to \mathbb{R}^{n-1}$ given by $y \mapsto g(r,y)$. The claim now follows from the above and the following two observations:

(a) For any s, z we have $(f \circ \Theta^{-1})(s,z) = (s, g(s,z)) = (s, \varphi_s(z))$.
(b) It follows from (a) that for $w \in \mathbb{R}^{n-1}$ we have

$$w \in r\text{-slice of } f(I \times J) \quad \Longleftrightarrow \quad w \in \varphi_r(J). \qquad \boxplus$$

Now we can conclude the proof of Step 1:

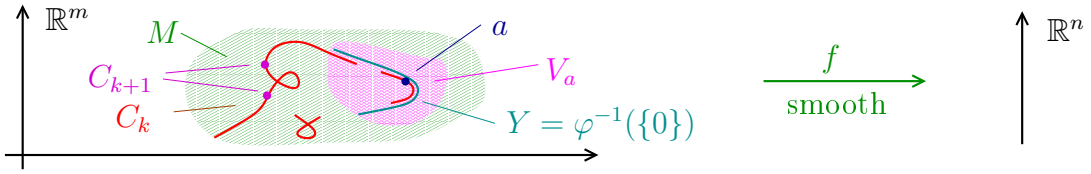
(a) Since $\dim(J) = m-1$ we see that for each $r \in I$ the right hand side of the claim has measure zero by our induction hypothesis.
(b) As we mentioned above, C is closed. This implies that $C \cap (I \times J)$ is compact. Therefore it follows from (a) together with Lemma 30.10 that the set of critical values of $f \circ \Theta^{-1}$ in $I \times J$ has measure zero.
(c) Since Θ is a diffeomorphism it follows from (b) and the trivial observation on page 701 that the set of critical values of f in $W_a := \Theta^{-1}(I \times J)$ has measure zero.
(d) We have now shown that each $a \in C \setminus C_1$ admits a neighborhood $W_a \subset C \setminus C_1$ such that $f(W_a \cap (C \setminus C_1))$ has measure zero.
(e) By the Countable Covering Lemma 9.2 we can cover $C \setminus C_1$ by countably many of the W_a. Therefore we can cover $f(C \setminus C_1)$ by countably many of the $f(W_a)$.
(f) It follows from (d), (e) and the Measure Zero-Basics Lemma 30.4 that $f(C \setminus C_1)$ has indeed measure zero.

Step 2. *For each $k \in \mathbb{N}$ the set $f(C_k \setminus C_{k+1}) \subset \mathbb{R}^n$ has measure zero.*
Let $a \in C_k \setminus C_{k+1}$. Since $a \notin C_{k+1}$ there exists a k-th partial derivative $\varphi \colon M \to \mathbb{R}$ of some f_j such that some partial derivative of φ does not vanish at a. Note that this means that a is a regular point of $\varphi \colon M \to \mathbb{R}$. By the Regular Value-Open Subset Lemma 26.1 we know that the set of regular *points* of φ is an open subset of M, thus there exists an open neighborhood $V_a \subset M \setminus C_{k+1}$ of a that consists only of regular points of $\varphi \colon M \to \mathbb{R}$.

We set $Y := \varphi^{-1}(0)$. Note that it follows from the Regular Value Theorem 26.4 that Y is a codimension-one submanifold of V_a. By definition of C_k all k-th partial derivatives of f vanish on C_k, in particular φ vanishes on C_k, which implies that $C_k \cap V_a \subset Y = \varphi^{-1}(0)$.

Claim. $f(C_k \cap V_a) \subset$ critical values of $f|_Y \colon Y \to \mathbb{R}^n$.

Proof. Let $P \in C_k \cap V_a$. Since $P \in C$ we see that $\mathrm{D}f_P \colon \mathrm{T}_P M \to \mathbb{R}^n$ is not an epimorphism. But this implies that $\mathrm{D}(f|_Y)_P = (\mathrm{D}f_P)|_{\mathrm{T}_P Y} \colon \mathrm{T}_P Y \to \mathbb{R}^n$ is also not an epimorphism. Thus we see that P is a critical point of $f|_Y \colon Y \to \mathbb{R}^n$ which implies that $f(P)$ is a critical value of $f|_Y \colon Y \to \mathbb{R}^n$. ⊞



Now we can conclude the proof of Step 2:

(a) Since Y is a smooth manifold of dimension $m-1$ we obtain from our induction hypothesis that the right-hand side of the claim is a set of measure zero.

(b) It follows from (a) together with the Measure-Zero Properties Proposition 30.2 (1) that each $a \in C_k \setminus C_{k+1}$ admits an open neighborhood $V_a \subset C_k \setminus C_{k+1}$ such that $f(V_a \cap (C_k \setminus C_{k+1}))$ has measure zero.

(c) By the Countable Covering Lemma 9.2 we can cover $C_k \setminus C_{k+1}$ by countably many of the V_a. Therefore we can cover $f(C_k \setminus C_{k+1})$ by countably many of the $f(V_a)$.

(d) It follows from (b), (c) and the Measure Zero-Basics Lemma 30.4 that $f(C_k \setminus C_{k+1})$ has indeed measure zero.

Step 3. *If $k > \frac{m}{n} - 1$, then the set $f(C_k) \subset \mathbb{R}^n$ has measure zero.*

Let $a \in C_k$ and let V_a be an open cube that is a neighborhood of a in M and which satisfies $\overline{V}_a \subset M$.

Claim. There exists some $D \in \mathbb{R}$ such that for each closed cube $W \subset \overline{V}_a$ of side length s and which contains a point $b \in C_k$ we have

$$\|f(x) - f(b)\| \leq D \cdot s^{k+1} \qquad \text{for each } x \in W.$$

Proof. Since f is smooth and since $\overline{V}_a$ is compact we can set

$$M := \text{maximum of the absolute value of all } (k+1)\text{-st partial derivatives of } f \text{ on } \overline{V}_a.$$

We denote by $f_1, \ldots, f_n$ the coordinate functions of f.

Next let $W \subset \overline{V}_a$ be a closed cube of side length s which contains a point $b \in C_k$. Let $i \in \{1, \ldots, n\}$. Note that for $b \in C_k$ the k-th Taylor polynomial $p(f_i, b)_k$ of f_i at the point b, which we introduced on page 535, is actually the constant polynomial $f_i(b)$. Thus we see that for each $x \in W$ we have

$$|f_i(x) - f_i(b)| = |f_i(x) \underbrace{- p(f,b)_k(x)}_{= f_i(b)}| \overset{\text{Corollary 19.8}}{\leq} \frac{m^{k+1} \cdot M}{(k+1)!} \cdot \|x - b\|^{k+1} \overset{\substack{\text{since } x, b \text{ are contained in an} \\ m\text{-dimensional cube of side length } s}}{\leq} \frac{m^{k+1} \cdot M}{(k+1)!} \cdot (\sqrt{m} \cdot s)^{k+1}.$$

Next recall that given any $(y_1, \ldots, y_n) \in \mathbb{R}^n$ we have the elementary inequality

$$\|(y_1, \ldots, y_n)\| \;=\; \sqrt{y_1^2 + \cdots + y_n^2} \;\leq\; n \cdot \max\{|y_1|, \ldots, |y_n|\}.$$

Combining these two inequalities we see that

$$\|f(x) - f(b)\| \;\leq\; \underbrace{n \cdot \tfrac{m^{k+1} \cdot M}{(k+1)!} \cdot (\sqrt{m})^{k+1}}_{=:D} \cdot s^{k+1}$$

⊞

Note that it follows from the claim for each cube $W \subset \overline{V}_a$ of side length s and which contains a point in C_k we have

$$f(\underbrace{W}_{\text{vol}=s^m}) \;\subset\; \begin{array}{c}\text{closed ball in } \mathbb{R}^n \text{ of} \\ \text{radius } D \cdot s^{k+1}\end{array} \;\subset\; \underbrace{\text{closed cube in } \mathbb{R}^n \text{ of side length } D \cdot s^{k+1}}_{\text{vol}=D^n \cdot s^{(k+1)n}}.$$

Here comes the key observations:

> If $k > \frac{m}{n} - 1$, then it follows that $(k+1)n > m$, which implies that the smaller s, the more the volume shrinks by applying f.

We now have to turn this observation into a proper argument.

Claim. The set $f(C_k \cap \overline{V}_a)$ has measure zero.

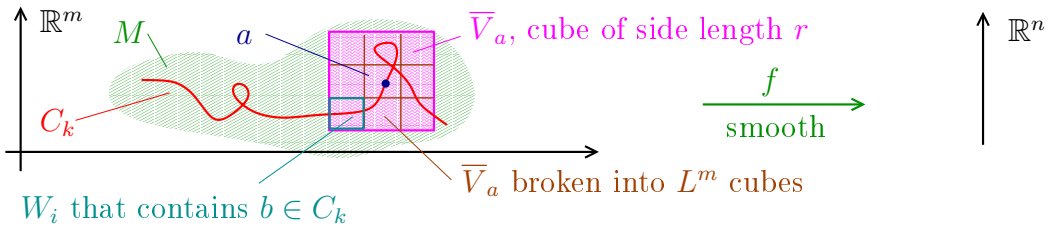
Proof. Let $\epsilon > 0$. We denote by r the side length of the cube $\overline{V}_a$. Since $m - (k+1) \cdot n < 0$ there exists an $L \in \mathbb{N}$ such that

$$D^n \cdot r^{(k+1) \cdot n} \cdot L^{m-(k+1) \cdot n} \;<\; \epsilon.$$

We choose L as above and we break $\overline{V}_a$ into L^m closed cubes $W_1, \ldots, W_{L^m}$ of side length $\frac{r}{L}$. We set

$$I \;:=\; \{i \in \{1, \ldots, L^m\} \,|\, C_k \cap W_i \neq \varnothing\}.$$

We see that



$$f(C_k \cap \overline{V}_a) \;\subset\; f\Big(\bigcup_{i \in I} W_i\Big) \;=\; \bigcup_{i \in I} f(W_i) \;\underset{\uparrow}{\subset}\; \bigcup_{i \in I} \text{closed cube of volume } D^n \cdot (\tfrac{r}{L})^{(k+1)n}.$$

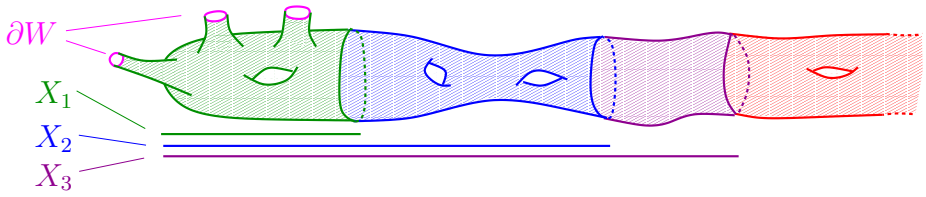
by the above since each such W_i contains a point in C_k

It follows from the choice of L and the fact that $|I| \leq L^m$ that the sum of the volumes of the cubes to the right is at most $L^m \cdot D^n \cdot (\frac{r}{L})^{(k+1)n}$, which by choice of L is $< \epsilon$. We have now shown that we can cover $f(C_k \cap \overline{V}_a)$ by closed cubes whose volumes add up to less than ϵ. It follows from the Measure Zero-Basics Lemma 30.4 (4) that $f(C_k \cap \overline{V}_a)$ has indeed measure zero. ⊞

Now we can conclude the proof of Step 3:

(a) We have just shown that each $a \in C_k$ admits a neighborhood $\overline{V}_a \subset M$ such that $f(C_k \cap \overline{V}_a)$ has measure zero.
(b) By the Countable Covering Lemma 9.2 we can cover C_k by countably many of the $\overline{V}_a$.
(c) It follows from (a) and (b), together with the Measure Zero-Basics Lemma 30.4 (2), that $f(C_k)$ has indeed measure zero.

Step 4. *Conclusion of the argument.*
We pick some $k \in \mathbb{N}$ with $k > \frac{m}{n} - 1$. Then we have



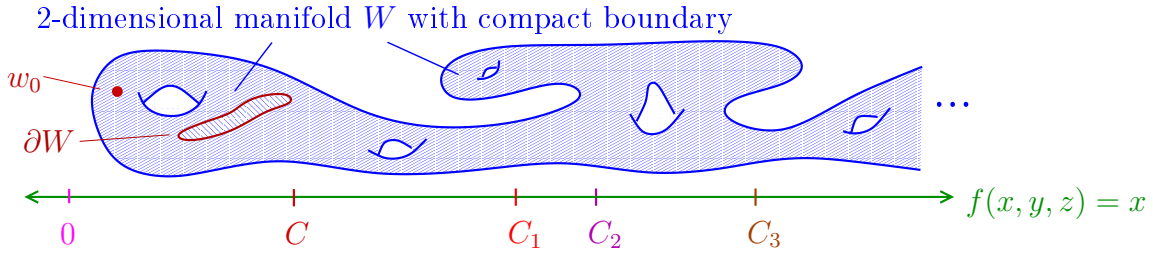
$$f(C) = f\Big((C \setminus C_1) \cup \bigcup_{i=1}^{k-1} (C_i \setminus C_{i+1}) \cup C_k\Big) = \underbrace{f(C \setminus C_1)}_{\substack{\text{measure zero} \\ \text{by Step 1}}} \cup \bigcup_{i=1}^{k-1} \underbrace{f(C_i \setminus C_{i+1})}_{\substack{\text{measure zero} \\ \text{by Step 2}}} \cup \underbrace{f(C_k)}_{\substack{\text{measure zero} \\ \text{by Step 3}}}.$$

It follows from the Measure Zero-Basics Lemma 30.4 (2) that $f(C)$, i.e. the set of critical values of f, has measure zero. ■

31.2. **Applications of Sard's Theorem.** In this section we give several applications of Sard's Theorem. Our first proposition of this section often allows us to reduce a statement about non-compact smooth manifolds to a statement about compact smooth manifolds.

Proposition 31.2. (Compact Submanifold Exhaustion Proposition) Let W be a connected n-dimensional smooth manifold with compact boundary. There exists a sequence $X_1, X_2, \ldots$ of n-dimensional smooth submanifolds of W with the following four properties:[318]

(0) We have $\partial W \subset X_1$.
(1) For each $i \in \mathbb{N}$ we have $X_i \subset \overset{\circ}{X}_{i+1}$.
(2) Each X_i is compact and connected.
(3) We have $\bigcup_{i \in \mathbb{N}} \overset{\circ}{X}_i = W$.



Remark. There is an analogue of the Compact Submanifold Exhaustion Proposition 31.2 if ∂W is non-compact. Since that statement is more technical to formulate we postpone it to Proposition **??**.

Proof. Let W be a connected n-dimensional smooth manifold. If W is empty, then there is nothing to show, so we might as well assume that W is non-empty. We pick a point $w_0 \in W$. By the Manifold Exhaustion Lemma 21.2 there exists a smooth exhaustion function on W,

[318] In particular we see that the X_i form a compact exhaustion of W in the sense of the definition on page 338.

i.e. there exists a smooth function $f\colon W \to \mathbb{R}_{\geq 0}$ with the property that for every $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of W. Since ∂W is compact it follows from the Compact Image Lemma 2.13 that there exists a $C \in \mathbb{R}_{\geq 0}$ such that $f(\partial W) \subset (-\infty, C]$ and such that $C \geq f(w_0)$.

It follows from Sard's Theorem 31.1 and the Full Measure-Density Proposition 30.3 (2) that there exists a strictly increasing sequence $C < C_1 < C_2 < C_3 < \dots$ of regular values of f such that $\lim_{i\to\infty} C_i = \infty$. For each $i \in \mathbb{N}$ we denote by X_i the path-component of $f^{-1}((-\infty, C_i])$ that contains w_0. By Exercise 26.6, which is a reasonably straightforward consequence of the Regular Value Theorem 26.4, and by our choice of f we know that each X_i is a compact n-dimensional submanifold with $\partial_0 X_i = X_i \cap f^{-1}(C_i)$. It follows from the Codimension-Zero Submanifold Proposition 19.38 that $\overset{\circ}{X}_i = X_i \cap f^{-1}((-\infty, C_i))$. From this observation, and from the fact that the C_i are strictly increasing we obtain that for each $i \in \mathbb{N}$ we have $X_i \subset \overset{\circ}{X}_{i+1}$. We have now shown that the X_i satisfy Properties (1) and (2).

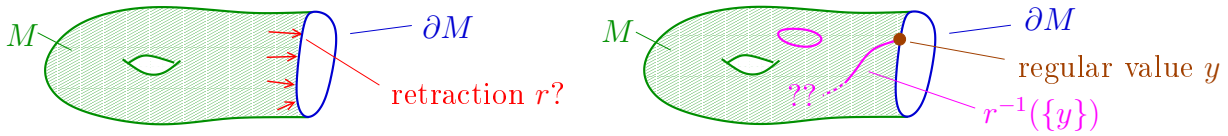
Now let $P \in W$. Since W is path-connected there exists a path $\gamma\colon [0,1] \to W$ from w_0 to P. Since $[0,1]$ is compact it follows again from the Compact Image Lemma 2.13 and from $\lim_{i\to\infty} C_i = \infty$ that there exists an i with $\gamma([0,1]) \subset f^{-1}((-\infty, C_i))$. By the above this implies that $P \in \overset{\circ}{X}_i$. We have thus shown that (3) is also satisfied. ■

To start our next application we need to recall the following definition from page 433.

Definition. Let X be a topological space. We say a subset $A \subset X$ is a retract of X if there exists a retraction $r\colon X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

Proposition 31.3. (Boundary Non-Retraction Proposition) Let M be a *compact* non-empty smooth manifold. There is no retraction from M to ∂M.[319]

Remark. In the Fundamental Class-of-Boundary Corollary 100.11 we will give an alternative proof of the Boundary Non-Retraction Proposition 31.3 and in Corollary 106.28 we will extend the conclusion of the Boundary Non-Retraction Proposition 31.3 to topological manifolds.



Proof. Let M be a compact non-empty smooth manifold. We suppose that there exists a retraction $M \to \partial M$. It follows from the Replace-by-Smooth Retraction 29.3 that there exists in fact a smooth retraction $r\colon M \to \partial M$. Since M is non-empty we obtain from Sard's Theorem 31.1 that the map $r\colon M \to \partial M$ admits a regular value y. Since M is

[319]The adjective "compact" is of course necessary, for example the smooth manifold $M = [0,\infty)$ admits a retraction onto its boundary $\partial M = \{0\}$.

compact we obtain from the Regular Value Theorem 26.4 that $W := r^{-1}(y)$ is a proper compact 1-dimensional submanifold of M. Note that

$$\partial W \underset{\text{since } W \text{ is a proper submanifold}}{=} W \cap \partial M = \{x \in \partial M \,|\, r(x) = y\} \underset{\text{since } r = \mathrm{id} \text{ on } \partial M}{=} \{y\}.$$

Thus we see that ∂W consists of a single point. But it follows from the Smooth 1-Dimensional Manifold Classification Theorem 22.7, that the boundary of a compact 1-dimensional smooth manifold consists of an *even* number of points. ■

31.3. **The Brouwer Fixed Point Theorem I.** The Boundary Non-Retraction Proposition 31.3 from the last section allows to prove the famous Brouwer Fixed Point Theorem which was first proved by Jacques Hadamard [**Had1910**] and Luitzen Brouwer [**Brou1912a**].

Theorem 31.4. (Brouwer Fixed Point Theorem) Every map $f\colon \overline{B}^n \to \overline{B}^n$ admits a fixed point, i.e. for every map $f\colon \overline{B}^n \to \overline{B}^n$ there exists a point $x \in \overline{B}^n$ such that $f(x) = x$.[320]

Remark. The Brouwer Fixed Point Theorem 31.4 admits many different proofs. We provide two more proofs on page 1618 and on page 2118. A fairly elementary proof is alternatively given in [**Miln1978**].

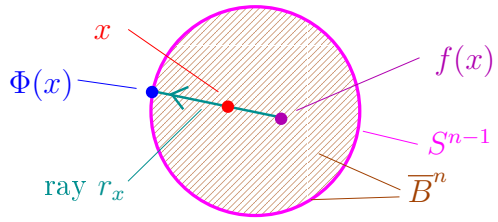
Proof. First let $f\colon \overline{B}^n \to \overline{B}^n$ be an arbitrary continuous map.

Claim 1. Given $x \in \overline{B}^n$ with $x \neq f(x)$ the open ray $r_x = \{f(x) + t \cdot (x - f(x)) \,|\, t > 0\}$ contains a unique point on S^{n-1}.

Proof. We consider the map

$$\begin{array}{rcl} \rho_x\colon \mathbb{R} & \to & \mathbb{R}_{\geq 0} \\ t & \mapsto & \|f(x) + t \cdot (x - f(x))\|^2 \underset{\text{follows from } \|v+w\|^2 = \langle v+w, v+w\rangle}{=} \|f(x)\|^2 + 2t \cdot \langle f(x), x - f(x)\rangle + t^2 \cdot \|x - f(x)\|^2. \end{array}$$

Since $x \neq f(x)$ we see that ρ_x is a quadratic function with $\lim_{t \to \pm\infty} \rho_x(t) = \infty$. Therefore we obtain from $\rho_x(0) = \|f(x)\| \leq 1$ together with an elementary calculus argument that $\rho_x^{-1}([0,1])$ is a compact interval.



It follows from this observation together with $\rho_x(0) = \|f(x)\| \leq 1$ and $\rho_x(1) = \|x\| \leq 1$ that there exists a unique $t \in (0, \infty)$ with $\rho_x(t) = 1$. This shows that the open ray r_x contains a unique point on S^{n-1}. ⊞

Now we suppose that $f\colon \overline{B}^n \to \overline{B}^n$ has no fixed points. It follows from Claim 1 that for each $x \in \overline{B}^n$ the open ray $r_x = \{f(x) + t \cdot (x - f(x)) \,|\, t > 0\}$ contains a unique point

[320] How can one prove the statement for $n = 1$ using elementary methods from real analysis?

on S^{n-1}. Thus we can consider the following map:

$$\begin{array}{rcl} \Phi\colon \overline{B}^n & \to & \overline{B}^n \\ x & \mapsto & \text{the unique intersection point of } S^{n-1} \text{ with the} \\ & & \text{uniquely determined open ray from } f(x) \text{ to } x. \end{array}$$

Claim 2. The map Φ is continuous.

Proof. As we discussed in Claim 1, for every $x \in \overline{B}^n$ there exists a unique $t_x > 0$ with $\rho_x(t_x) = \|f(x)+t_x\cdot(x-f(x))\|^2 = 1$, and by definition we have $\Phi(x) = f(x)+t_x\cdot(x-f(x))$. Thus it suffices to show that the map $x \mapsto t_x$ is continuous. One can determine t_x through the quadratic equation

$$1 \;=\; \|f(x) + t_x \cdot (x - f(x))\|^2 \;=\; \|f(x)\|^2 + t_x \cdot 2\langle f(x, x - f(x))\rangle + t_x^2 \cdot \|x - f(x)\|^2.$$

The quadratic formula for polynomials of degree two is continuous in the coefficients, thus we see that the map $x \mapsto t_x \in \mathbb{R}_{>0}$ is indeed continuous.[321] ⊞

It is evident that $\Phi(x) = x$ for all $x \in S^{n-1}$ and that $\Phi(x) \in S^{n-1}$ for all $x \in S^{n-1}$. The map Φ is thus a retraction from $\overline{B}^n$ to S^{n-1}. But according to the Boundary Non-Retraction Proposition 31.3 this is not possible. Thus we have obtained a contradiction. ■

The Brouwer Fixed Point Theorem pops up many times in mathematics. For example we can use it to prove the following theorem in linear algebra.

Theorem 31.5. (Perron-Frobenius Theorem) Let $A = (a_{ij})$ be an $n \times n$-real matrix. If all entries are positive, then A has a positive eigenvalue λ with an eigenvector v such that all entries of v are non-negative.

Remark. There are more precise statements one can prove about matrices with positive entries we refer to [**Meyr2000**, Section 8.2] and also to

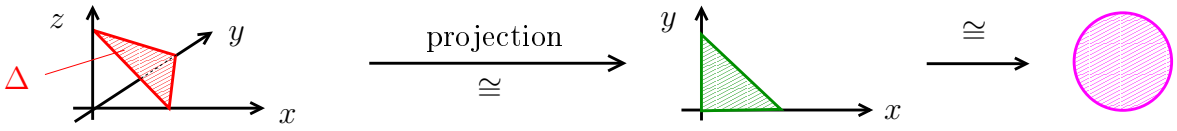
`https://en.wikipedia.org/wiki/Perron-Frobenius_theorem`

for details. Supposedly the Perron-Frobenius Theorem and some of the more refined results mentioned in [**Meyr2000**, Section 8.2] play a major role in Google's algorithm, see e.g.

`http://www.math.pku.edu.cn/teachers/yaoy/Fall2011/lecture07.pdf`

for more information.

Proof. We introduce two players:



(1) Given $v = (v_1, \ldots, v_n) \in \mathbb{R}^n$ we write $|v| := \sum_{i=1}^{n} |v_i|$.

[321] One could also use the home grown Proposition 5.42, if one prefers more fancy arguments.

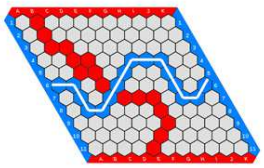
(2) We consider

$$\Delta := \{(t_1, \ldots, t_n) \in [0,1]^n \,\big|\, |v| = 1\}.$$

By projecting Δ onto $\mathbb{R}^{n-1}$ and using the Convex-to-Ball Proposition 2.20 one sees that Δ is homeomorphic to $\overline{B}^{n-1}$. It follows immediately from this observation and from the Brouwer Fixed Point Theorem 31.4 that any self-map $f\colon \Delta \to \Delta$ has a fixed point.

Now let $A = (a_{ij})$ be an $n \times n$-real matrix such that all entries are positive. We consider the map

$$\begin{array}{rcl} f\colon \Delta & \to & \Delta \\ v = (v_1, \ldots, v_n) & \mapsto & \frac{A \cdot v}{|A \cdot v|}. \end{array}$$



Note that this map is defined since our hypothesis that all a_{ij} are positive and the fact that all entries of v are non-negative and that at least one entry of v is positive imply that $A \cdot v \neq 0$. As we had just discussed above, the map $f\colon \Delta \to \Delta$ has a fixed point $v \in \Delta$. But this means that $A \cdot v = |A \cdot v| \cdot v$. Put differently, we have just shown that v is an eigenvector to the positive eigenvalue $|A \cdot v|$. ■

We conclude this discussion of the Brouwer Fixed Point Theorem 31.4 with two applications outside of mathematics:

(1) The board game "Hex" was invented in 1942 by Piet Hein[322] and it was re-invented in 1948 by John Nash.[323] The game is illustrated in the figure below and an online version can be found at

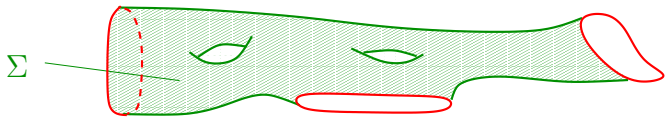
`http://www.lutanho.net/play/hex.html`

David Gale [**Gal1979**] showed in 1979 that the statement that the board game "Hex" cannot end in a draw, is equivalent to the Brouwer Fixed Point Theorem 31.4. We also refer to [**Gh2014**, p. 102] for a discussion of Hex and the Brouwer Fixed Point Theorem 31.4.

11×11 Hex gameboard showing a winning configuration for Blue

(2) The Brouwer Fixed Point Theorem 31.4 can also be used to show the existence of a "Nash equilibrium" in game theory. We refer to the following website for more information:

`https://en.wikipedia.org/wiki/Nash_equilibrium`.



[322] Piet Hein (1905-1996) was a Danish mathematician.

[323] John Nash (1928-2015) was an American mathematician who was awarded the Nobel prize in economics in 1994. The movie "a beautiful mind" was based on his struggles with schizophrenia.

Exercises for Chapter 31.

Exercise 31.1. In the figure below we show Σ, the surface of genus two minus three open disks. By the Boundary Non-Retraction Proposition 31.3 we know that there is no retraction from Σ to $\partial\Sigma$.

(a) Does there exist a retraction to the union of two boundary components?
(b) Does there exist a retraction to a single boundary component?

Exercise 31.2. We say that a map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ has *bounded displacement* if there exists a $C \in \mathbb{R}$ such that for every $x \in \mathbb{R}^n$ we have $\|x - f(x)\| \leq C$. Show that every map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ of bounded displacement is onto.
Hint. Use the Brouwer Fixed Point Theorem 31.4.

Exercise 31.3. Let M be a smooth manifold and let $K, L \subset M$ be disjoint closed subsets of M. Show that there exist codimension-zero submanifolds A and B of M, which are closed subsets of M, such that $K \subset A$, $L \subset B$, $A \cup B = M$ and such that $A \cap B = \partial_0 A = \partial_0 B$.
Hint. Use Exercise 26.6 and use Urysohn's Lemma 21.7 for Manifolds.

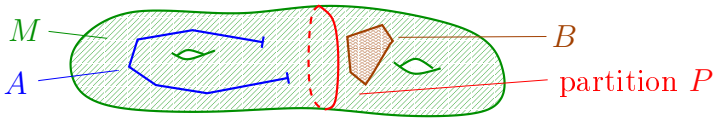
Exercise 31.4. Let M be a smooth manifold, let U be an open subset of M and let K be a *compact* subset of M that is contained in U. Show that there exists a *compact* codimension-zero submanifold N of M with $K \subset N \subset U$.
Remark. The exercise is related to Exercise 31.3, but the compactness condition and requirement adds a welcome extra layer of difficulty.

Exercise 31.5. Let $n \in \mathbb{N}$. Show that the subset

$$\{A \in \mathrm{M}(n \times n, \mathbb{R}) \mid \det(A) = 0\} \subset \mathrm{M}(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$$

has measure zero.
Hint. There are many approaches to proving this statement. You could for example play with the map

$$\begin{aligned} \Phi\colon \overbrace{\mathbb{R}^n \times \cdots \times \mathbb{R}^n}^{n\text{-1 copies}} \times \mathbb{R}^{n-1} &\mapsto \mathrm{M}(n \times n, \mathbb{R}) \\ (v_1, \ldots, v_{n-1}, (\lambda_1, \ldots, \lambda_{n-1}) &\mapsto \Big(v_1 \ \ldots \ v_{n-1} \ \sum_{i=1}^{n-1} \lambda_i \cdot v_i\Big). \end{aligned}$$



You could also make use of the fact that a matrix has determinant zero if and only if the column vectors are linearly dependent.

Exercise 31.6.

(a) Let X be a topological space and let A and B be disjoint subsets of X. As on page 389 we say a subset $P \subset X$ is a *partition between A and B*, if there exist disjoint open subsets U and V of X with $A \subset U$, $B \subset V$ and $X \setminus P = U \cup V$.

Show that if M is an n-dimensional smooth manifold, then given any two disjoint closed subsets A and B there exists a partition P between A and B that is an $(n-1)$-dimensional smooth manifold of M.

Remark. This part of the exercise is quite similar to Exercise 31.3.

(b) We iteratively define classes $\mathcal{D}_{-1}, \mathcal{D}_0, \mathcal{D}_1, \ldots$ of topological spaces:

- We define $\mathcal{D}_{-1}$ to be the class consisting only of the empty topological space.
- Suppose that for some $n \in \mathbb{N}_0$ we have defined $\mathcal{D}_{-1}, \mathcal{D}_0, \ldots, \mathcal{D}_{n-1}$. Given a topological space X we say $X \in \mathcal{D}_n$ if for any two closed disjoint subsets A and B of X there exists a partition P between A and B with $P \in \mathcal{D}_{n-1}$. (We refer to Exercise 11.10 for the definition of a partition.)

We define $\mathcal{D}_\infty$ to be the class of all topological spaces. Given a topological space X we define, as in Exercise 31.6, the *large inductive dimension* $\operatorname{ind}(X)$ as follows:

$$\operatorname{Ind}(X) \;:=\; \min\{n \in \mathbb{Z}_{\geq -1} \cup \{\infty\} \,|\, X \in \mathcal{D}_n\}.$$

Show that for every n-dimensional smooth manifold M we have $\operatorname{ind}(M) \leq n$.

32. Complex manifolds

As a slight detour from the main story, namely the development of the theory of smooth manifolds, let us now give a very short introduction to complex manifolds. Complex manifolds are topological manifolds that are equipped with a holomorphic atlas. As we will see, complex manifolds are smooth manifolds with particularly nice properties. Throughout these notes they will play a role every now and then.

Convention. Let $n \in \mathbb{N}_0$. Throughout these notes we will use the isomorphism

$$\begin{array}{rcl} \mathbb{R}^{2n} = (\mathbb{R}^2)^n & \to & \mathbb{C}^n \\ (x_1, y_1, \ldots, x_n, y_n) & \mapsto & (x_1 + y_1\,\mathrm{i}, \ldots, x_n + y_n\,\mathrm{i}) \end{array}$$

of real vector spaces to identify $\mathbb{R}^{2n}$ with $\mathbb{C}^n$.

The following elementary lemma is the essential tool for describing complex linear maps by real matrices.

Lemma 32.1. Given any $a, b \in \mathbb{R}$ the following diagram commutes:

$$\begin{array}{ccc} \mathbb{R}^2 & \xrightarrow{v \mapsto \left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right) \cdot v} & \mathbb{R}^2 \\ {\scriptstyle (x,y)\mapsto x+y\mathrm{i}}\big\downarrow \cong & & \cong \big\downarrow {\scriptstyle (x,y)\mapsto x+y\mathrm{i}} \\ \mathbb{C} & \xrightarrow{z \mapsto (a+b\mathrm{i})\cdot z} & \mathbb{C}. \end{array}$$

Proof. The lemma follows immediately from an elementary calculation. ∎

32.1. Holomorphic functions.

First we recall the definition of a holomorphic function.

Definition. Let $U \subset \mathbb{C}$ be an open subset and let $f\colon U \to \mathbb{C}$ be a map.

(1) We say f is holomorphic in $z_0 \in U$, if the limit

$$\frac{d}{dz} f(z_0) \;:=\; f'(z_0) \;:=\; \lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0} \;\in \mathbb{C}$$

exists. We refer to $\frac{d}{dz} f(z_0) = f'(z_0)$ as the derivative of f at z.

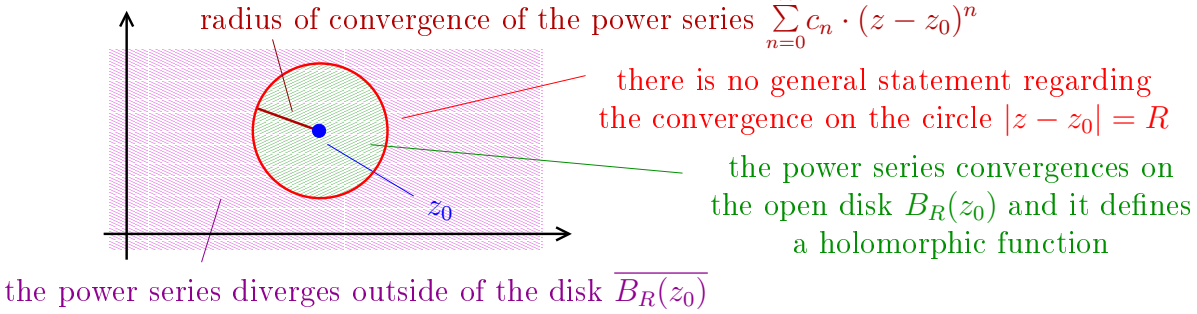
(2) We say f is holomorphic if f is holomorphic in each $z_0 \in U$.

Example. It follows immediately from the definition that the function $f(z) = z$ is holomorphic. Furthermore it is elementary to show products, fractions, sums and compositions of holomorphic functions are again holomorphic. This shows in particular that maps described by polynomials are holomorphic.

Proposition 32.2. (Complex Power Series Convergence Proposition) Let $(c_n)_{n \in \mathbb{N}_0}$ be a sequence of complex numbers and let $z_0 \in \mathbb{C}$. We consider the radius of convergence

$$R \;:=\; \sup\left\{ |z - z_0| \;\middle|\; \sum_{n=0}^{\infty} c_n \cdot (z - z_0)^n \text{ converges} \right\}.$$

The following two statements hold:



(1) Let $z \in \mathbb{C}$. The series $\sum_{n=0}^{\infty} c_n \cdot (z - z_0)^n$ converges if $|z - z_0| < R$ and it diverges if $|z - z_0| > R$.

(2) The map

$$\begin{aligned} B_R(z_0) &\to \mathbb{C} \\ z &\mapsto \sum_{n=0}^{\infty} c_n \cdot (z - z_0)^n \end{aligned}$$

is holomorphic with derivative

$$\begin{aligned} B_R(z_0) &\to \mathbb{C} \\ z &\mapsto \sum_{n=0}^{\infty} c_n \cdot n \cdot (z - z_0)^{n-1}. \end{aligned}$$

Proof. This proposition is proved in [**Lang1999**, Theorem II.5.1] or alternatively [**Jä2011**, Chapter 1.2]. ■

Via the above identification $\mathbb{C} = \mathbb{R}^2$ we can view a map $f\colon U \to \mathbb{C}$ as above also as a map from an open subset of $\mathbb{R}^2$ to $\mathbb{R}^2$. The following proposition clarifies the relationship between holomorphicity and smoothness in the sense of the definition on page 532.

Proposition 32.3. (Smooth-Complex Differentiability Proposition) Let $U \subset \mathbb{C}$ be an open subset and let $f\colon U \to \mathbb{C}$ be a map. Given $z \in U$ we write $u(z) := \mathrm{Re}(f(z))$ and $v(z) = \mathrm{Im}(f(z))$.

(1) For $z_0 \in U$ and $a, b \in \mathbb{R}$ the following two statements are equivalent:
   (a) The map $f\colon U \to \mathbb{C}$ is holomorphic in z_0 with derivative $f'(z_0) = a + b\mathrm{i}$.
   (b) The map
   $$\begin{aligned} U &\to \mathbb{C} = \mathbb{R}^2 \\ z &\mapsto (u(z), v(z)) \end{aligned}$$
   is differentiable in z_0, in the sense of the definition on page 535, with differential $\mathrm{D}f_{z_0} = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$.[324]

(2) The following two statements are equivalent:
   (a) The map $f\colon U \to \mathbb{C}$ is holomorphic.
   (b) The map $f\colon U \to \mathbb{C} = \mathbb{R}^2$ is smooth in the sense of the definition on page 532 and each differential is of the form $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$.

[324] By the Differential-from-Partial Derivatives Proposition 19.9 the condition that $\mathrm{D}f_{z_0}$ is of this form is equivalent to the statement that $\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}$ and $\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$. These two equations are sometimes called the Cauchy-Riemann equations.

Sketch of proof. Let $U \subset \mathbb{C}$ be an open subset and let $f\colon U \to \mathbb{C}$ be a map.

(1) Given any $z_0 \in U$ and given any $a, b \in \mathbb{R}$ we see that:

$$\begin{aligned}
&f \text{ is holomorphic in } z_0 \text{ with derivative } a+b\mathrm{i} \\
&\iff \lim_{h\to 0} \frac{f(z_0+h)-f(z_0)}{h} = a+b\mathrm{i} \\
&\iff \lim_{h\to 0} \frac{f(z_0+h)-f(z_0)-(a+b\mathrm{i})\cdot h}{h} = 0 \\
&\iff \underbrace{\lim_{h\to 0} \frac{f(z_0+h)-f(z_0)-(a+b\mathrm{i})\cdot h}{|h|}}_{\text{complex limit in } \mathbb{C}} = 0 \\
&\iff \underbrace{\lim_{w\to 0} \frac{f(z_0+w)-f(z_0)-\begin{pmatrix} a & -b \\ b & a \end{pmatrix}\cdot w}{\|w\|}}_{\text{real limit in } \mathbb{R}^2} = 0 \\
&\qquad \uparrow \text{ Lemma 32.1} \\
&\iff f \text{ is differentiable in } z_0 \text{ with } \mathrm{D}f_{z_0} = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}. \\
&\qquad \uparrow \text{ see the definition on page 535}
\end{aligned}$$

(2) This statement follows from (1) and the fact, see the Power Series Expansion Theorem 32.5 below, that for every holomorphic map its derivative is again holomorphic. In other words, all higher derivatives exist. This corresponds to our convention, that by "smooth" we mean that all higher derivatives exist. ∎

The definition of a complex function being holomorphic is almost verbatim the same as the definition of a real function being differentiable, we just replace $\mathbb{R}$ by $\mathbb{C}$. But rather surprisingly being holomorphic has many consequences which one is not used to from the world of real valued differentiable functions. In the following we recall some of the main results from complex analysis. But before we can state the first theorem we need to introduce a few definitions.

Definition.

(1) Given a subset U of $\mathbb{C}$, we define a path in U to be a map $\gamma\colon [a,b] \to U$.

(2) Let $U \subset \mathbb{C}$ be an open subset, let $f\colon U \to \mathbb{C}$ be a map and let $\gamma\colon [a,b] \to U$ be a smooth path. We define the path integral of f along γ as follows:

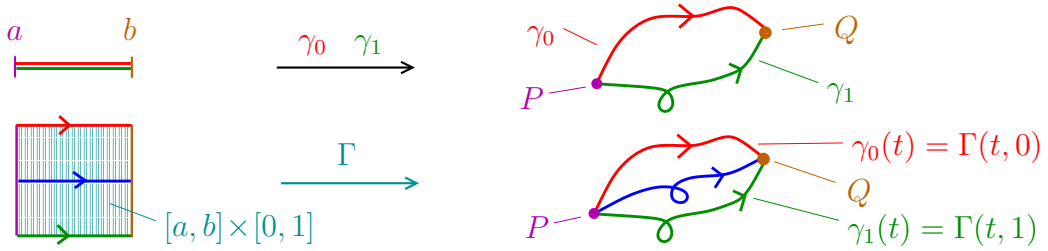
$$\int_\gamma f(z)\,dz \;:=\; \int_{t=a}^{t=b} \underbrace{f(\gamma(t))}_{\in\mathbb{C}} \cdot \underbrace{\gamma'(t)}_{\in\mathbb{C}}\,dt \;\in \mathbb{C}.$$

$\uparrow$ product of complex numbers

Examples.

(1) Let $U = \mathbb{C}\setminus\{0\}$, let $f(z) = \frac{1}{z}$ and let $\gamma\colon [0,1] \to \mathbb{C}\setminus\{0\}$ be the path given by $\gamma(t) = \exp(2\pi\mathrm{i}t)$, i.e. γ is a path that "goes counterclockwise once around the origin". Then

$$\int_\gamma f(z)\,dz \;=\; \int_{t=0}^{t=1} f(\gamma(t))\cdot\gamma'(t)\,dt \;=\; \int_{t=0}^{t=1} \frac{1}{\exp(2\pi\mathrm{i}t)}\cdot\exp(2\pi\mathrm{i}t)\cdot 2\pi\mathrm{i}\,dt \;=\; 2\pi\mathrm{i}.$$



(2) If γ is a constant path, then $\gamma'(t) \equiv 0$. This shows that the path-integral along a constant path is zero.

Definition. Let $U \subset \mathbb{C}$ be a subset. Two paths $\gamma_0, \gamma_1 \colon [a,b] \to U$ with the same starting point $P := \gamma_0(a) = \gamma_1(a)$ and the same endpoint $Q := \gamma_0(b) = \gamma_1(b)$ are called path-homotopic in U, if there exists a homotopy rel $\{a,b\}$ from γ_0 to γ_1. In other words, if there exists a map

$$\begin{array}{rcl} \Gamma \colon [a,b] \times [0,1] & \to & U \\ (s,t) & \mapsto & \Gamma(s,t), \end{array}$$

with the following properties

(a) for every $s \in [a,b]$ we have $\Gamma(s,0) = \gamma_0(s)$ and $\Gamma(s,1) = \gamma_1(s)$,
(b) for every $t \in [0,1]$ we have $\Gamma(a,t) = P$ and $\Gamma(b,t) = Q$.

The following theorem is the foundational result in complex analysis.

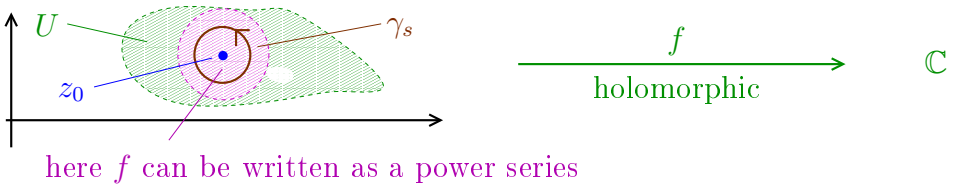
Theorem 32.4. (Cauchy Theorem) Let $U \subset \mathbb{C}$ be an open subset, let $f \colon U \to \mathbb{C}$ be a holomorphic function and let $\gamma, \delta \colon [a,b] \to U$ be two smooth paths. If γ and δ are path-homotopic, then

$$\int_\gamma f(z)\,dz \;=\; \int_\delta f(z)\,dz.$$

Proof. A proof of Cauchy's Theorem is given in every book on complex analysis, see e.g. [**Lang1999**, Theorem III.5.1]. ∎

The Cauchy Theorem **??** is the mother of all results in complex analysis. It is at the heart of many other results. We now give a hotchpotch list of theorems, which are more or less immediate consequences of the Cauchy Theorem 32.4, and which we will make use of later on.

Theorem 32.5. (Power Series Expansion Theorem) Let $U \subset \mathbb{C}$ be an open subset and let $f \colon U \to \mathbb{C}$ be holomorphic.



(1) If we are given a disk $B_r(z_0) \subset U$, then there exists a sequence $(c_n)_{n \in \mathbb{N}_0}$ of complex numbers such that

$$f(z) \;=\; \sum_{n=0}^{\infty} c_n \cdot (z - z_0)^n \qquad \text{for all } z \in B_r(z_0).$$

Furthermore for each $s \in (0,r)$ we have

$$c_n \;=\; \int_{\gamma_s} \frac{f(z)}{(z-z_0)^{n+1}}\,dz,$$

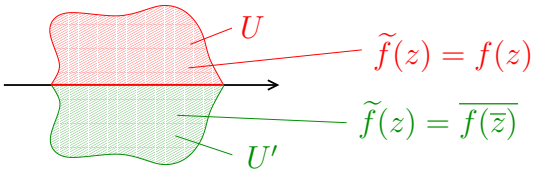
where $\gamma_s\colon [0,1] \to U$ is the path given by $\gamma_s(t) = z_0 + s \cdot \exp(2\pi i t)$.
(2) All derivatives of f are holomorphic.

Proof.

(1) This theorem is [**Lang1999**, Theorem III.7.2] or alternatively see [**Jä2011**, Chapter 3.2 Satz 3].
(2) This statement follows from Statement (1) together with the Complex Power Series Convergence Proposition 32.2. ■

Theorem 32.6. (Liouville's Theorem) Every bounded holomorphic map $f\colon \mathbb{C} \to \mathbb{C}$ is constant.

Proof. As we will see in Exercise 32.1, one can deduce Liouville's Theorem 32.6 from the Power Series Expansion Theorem 32.5 (1). Alternatively we refer to [**Lang1999**, Theorem III.7.5] or [**Jä2011**, Chapter 3.2] for a proof. ■



Proposition 32.7. (Schwarz Reflection Principle) Let U be an open subset of the upper half-plane $\{z \in \mathbb{C} \mid \mathrm{Im}(z) \geq 0\}$ and let $f\colon U \to \mathbb{C}$ be a continuous function with the following properties:

(1) f is holomorphic on $\mathring{U} = \{z \in U \mid \mathrm{Im}(z) > 0\}$,
(2) f only assumes real values on $U \cap \mathbb{R}$.

We set $U' := \{\overline{z} \mid z \in U\}$, i.e. U' is the reflection of U in the real axis. Then the function[325]

$$\begin{array}{rcl} \widetilde{f}\colon U \cup U' & \to & \mathbb{C} \\ z & \mapsto & \begin{cases} f(z), & \text{if } z \in U, \\ \overline{f(\overline{z})}, & \text{if } z \in U', \end{cases} \end{array}$$

is holomorphic.

Proof. This proposition is proved in [**Lang1999**, Chapter IX.1] or alternatively in [**Jä2011**, Chapter 3.3]. ■

Theorem 32.8. (Locally-a-Power Theorem) Let U be an open subset of $\mathbb{C}$. Furthermore let $f\colon U \to \mathbb{C}$ be a holomorphic function and let $z_0 \in U$ be a zero of f.

(1) If all derivatives of f at z_0 vanish, then f is zero in an open neighborhood of z_0.

[325] It follows from Lemma 1.8 (2) that $U \cup U'$ is an open subset of $\mathbb{C}$.

(2) If there exists a $k \in \mathbb{N}$ such that $f(z_0) = \cdots = f^{(k-1)}(z_0) = 0$ but $f^{(k)}(z_0) \neq 0$, then there exists an open neighborhood $V \subset U$ of z_0 and a holomorphic function $g\colon V \to \mathbb{C}$ with $g'(z_0) \neq 0$ such that $f(z) = (g(z))^k$ for all $z \in V$.

Proof. The first statement is an immediate consequence of the Power Series Expansion Theorem 32.5 together with the Complex Power Series Convergence Proposition 32.2 (2). The second statement follows from [**Jä2011**, Kapitel 3 Satz 10 and 12]. ■

Proposition 32.9. Let U be an open subset of $\mathbb{C}$ and let $f\colon U \to \mathbb{C}$ be a holomorphic function. If $V \subset U$ is a connected open subset such that $f|_V$ is not constant, then $f(V)$ is an open subset of $\mathbb{C}$.

Proof. We will prove the proposition in Exercise 32.6 using the Locally-a-Power Theorem 32.8 and using the Inverse Function Theorem 19.12. Alternatively see [**Jä2011**, Kapitel 3 Satz 13]. ■

Theorem 32.10. (Maximum Principle) Let U be an open connected subset of $\mathbb{C}$ and let $f\colon U \to \mathbb{C}$ be a holomorphic function. If the function $|f|\colon U \to \mathbb{R}_{\geq 0}$ has a local maximum, then f is constant.

Proof. We will prove the Maximum Principle in Exercise 32.7 using Proposition 32.9. Alternatively see [**Lang1999**, p. 271] or [**Jä2011**, Kapitel 3 Satz 14]. ■

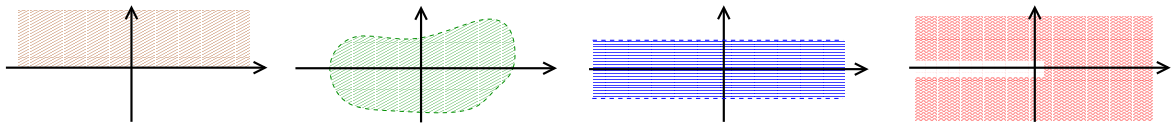
32.2. Biholomorphisms in the one-dimensional setting.

Definition. Let $f\colon U \to V$ be a map between two open subsets of $\mathbb{C}$. We say f is a biholomorphism if f is holomorphic, f is a bijection and $f^{-1}\colon V \to U$ is also holomorphic.

The following proposition shows that the only biholomorphisms of $\mathbb{C}$ are the obvious ones.

Theorem 32.11. Every biholomorphism $f\colon \mathbb{C} \to \mathbb{C}$ is an affine linear map, i.e. there exist $a, b \in \mathbb{C}$ such that $f(z) = a \cdot z + b$ for all $z \in \mathbb{C}$.

Proof. The proposition is proved in [**Lang1999**, Theorem V.5.3]. ■



Example. In some cases one can explicitly write down a biholomorphism. For example, for the upper half-plane $\mathbb{H} = \{x + \mathrm{i}y \mid y > 0\}$ and the open disk $\mathbb{D} = \{z \in \mathbb{C} \mid |z| < 1\}$ it is straightforward to verify that the maps

$$\begin{array}{rcl} \Phi\colon \mathbb{H} & \to & \mathbb{D} \\ z & \mapsto & \frac{z-\mathrm{i}}{z+\mathrm{i}} \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon \mathbb{D} & \to & \mathbb{H} \\ w & \mapsto & \frac{\mathrm{i}+\mathrm{i}w}{1-w} \end{array}$$

are biholomorphisms that are inverse to one another.

In general it is hard to write down an explicit biholomorphism between two open subsets of $\mathbb{C}$. One of the main sources of biholomorphisms is the Riemann Mapping Theorem. To formulate this fantastic theorem we need to introduce the following definition.

Definition. Let $U \subset \mathbb{C}$ be a subset. We say U is simply connected if U is non-empty, if U is path-connected and if each path $\gamma\colon [0,1] \to U$ with $\gamma(0) = \gamma(1)$ is path-homotopic to a constant map.

these open subsets are biholomorphic to $\mathbb{D}$ by the Riemann Mapping Theorem 32.12

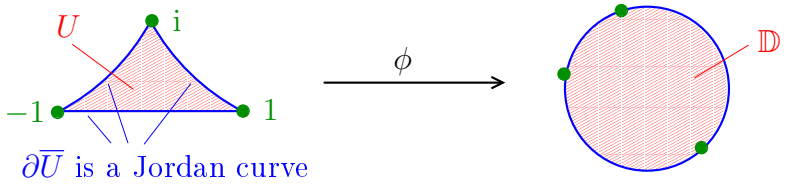
Theorem 32.12. (Riemann Mapping Theorem) Let $U \subset \mathbb{C}$ be a simply connected open subset U of $\mathbb{C}$. If $U \neq \mathbb{C}$, then U is biholomorphic to $\mathbb{D} = \{z \in \mathbb{C} \mid |z| < 1\}$.

Remark. The Riemann Mapping Theorem was first stated by Bernhard Riemann in 1851 in his doctoral thesis. The first rigorous proof was given by William Osgood in 1900, see [**Wals1973**].

Proof. The Riemann mapping theorem is proved in most textbooks on complex analysis, see e.g. [**Jä2011**, Chapter 10.1] or alternatively [**Lang1999**, Chapter X]. ■

In many applications it is also useful to know that the biholomorphism from the Riemann Mapping Theorem extends to the boundary of U and $\mathbb{D}$. To state the corresponding theorem we need one more definition.

Definition.



(1) We write $\overline{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$, called "$\mathbb{C}$ with a point at infinity", where we equip the set $\overline{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$ with the topology that we defined on page 122.

(2) Given $U \subset \overline{\mathbb{C}}$ we denote by $\overline{U}$ the closure of U in $\overline{\mathbb{C}}$.[326]

(3) A Jordan curve is the image of an embedding $S^1 \to \overline{\mathbb{C}}$.[327]

The following theorem was proved in 1913 by Constantin Carathéodory [**Cara1913**].[328]

Theorem 32.13. (Carathéodory Theorem) Let $U \subsetneq \mathbb{C}$ be a simply connected open subset U of $\mathbb{C}$ and let $\phi\colon U \to \mathbb{D}$ be a biholomorphism. If $\partial\overline{U}$ is a Jordan curve, then ϕ extends to a homeomorphism $\overline{U} \to \overline{\mathbb{D}}$.

Proof. A textbook proof of the theorem is provided in [**GM2005**, Chapter I.3]. ■

Example. We consider the open subset U of $\mathbb{C}$ that is shown in the figure above. It is a simply connected open proper subset of $\mathbb{C}$ and the boundary is clearly a Jordan curve. Thus it follows from the Riemann Mapping Theorem 32.12 and from Carathéodory's Theorem 32.13 that there exists a homeomorphism $\phi\colon \overline{U} \to \overline{\mathbb{D}}$ which restricts to a biholomorphism $\phi\colon U \to \mathbb{D}$.

[326] Let $U \subset \mathbb{C}$. It follows easily from the definition of $\overline{\mathbb{C}}$ that $\infty \in \overline{U}$ if and only if U is unbounded.

[327] On page 122 we mentioned that $\overline{\mathbb{C}}$ is Hausdorff. Therefore it follows from the Compact-Hausdorff Proposition 2.17 that a Jordan curve is the same as an injective map $S^1 \to \overline{\mathbb{C}}$.

[328] Constantin Carathéodory (1873-1950) was a Greek mathematician who was in particular a professor at the LMU in Munich.

32.3. **Holomorphic maps in the higher-dimensional setting.** We now move from the one-dimensional setting to the higher-dimensional case.

Definition. Let $U \subset \mathbb{C}^m$ be an open subset and let $f = (f_1, \dots, f_n) \colon U \to \mathbb{C}^n$ be a map.

(1) We say f is holomorphic if for every $i \in \{1, \dots, m\}$, every $j \in \{1, \dots, n\}$ and every point $(w_1, \dots, w_{i-1}, w_{i+1}, \dots, w_k) \in \mathbb{C}^{m-1}$ the map

$$\begin{array}{rcl} \overbrace{\{z \in \mathbb{C} \mid (w_1, \dots, w_{i-1}, z, w_{i+1}, \dots, w_k) \in U\}}^{\text{open subset of } \mathbb{C} \text{ by Exercise 5.10 (a)}} & \to & \mathbb{C} \\ z & \mapsto & f_j(w_1, \dots, w_{i-1}, z, w_{i+1}, \dots, w_k) \end{array}$$

is holomorphic.

(2) We say $f \colon U \to f(U)$ is a biholomorphism if f is holomorphic, if f is a bijection, if $f(U)$ is an open subset of $\mathbb{C}^n$ and if $f^{-1} \colon f(U) \to U$ is also holomorphic.

(3) Let $P \in U$. We say $f \colon U \to \mathbb{C}^m$ is a local biholomorphism at P if there exists an open neighborhood V of P and an open neighborhood W of $f(P)$ such that $f \colon V \to W$ is a biholomorphism.

Remark. It follows from the Smooth-Complex Differentiability Proposition 32.3 that every holomorphic map from an open subset $U \subset \mathbb{C}^m = \mathbb{R}^{2m}$ to $\mathbb{C}^n = \mathbb{R}^{2n}$ is in particular smooth.

Proposition 32.14. (Smooth-Complex Differentiability Proposition II) In the following let $U \subset \mathbb{C}^m$ be an open subset and let $f = U \to \mathbb{C}^n$ be a map. The following two statements are equivalent:

(1) The map $f \colon U \to \mathbb{C}^n$ is holomorphic.

(2) The map $f \colon U \to \mathbb{C}^n$, viewed as a map from an open subset of $\mathbb{C}^m = \mathbb{R}^{2n}$ to $\mathbb{C}^n = \mathbb{R}^{2n}$ is smooth and for every $P \in U$ the differential $\mathrm{D}f_P \colon \mathbb{C}^m = \mathbb{R}^{2n} \to \mathbb{C}^n = \mathbb{R}^{2n}$ is a complex linear map.

Proof. The proposition can be deduced quite easily from the Smooth-Complex Differentiability Proposition 32.3. We leave it to the reader to fill in the details. ∎

The following theorem is the holomorphic analogue of the Inverse Function Theorem 19.12.

Theorem 32.15. (Holomorphic Inverse Function Theorem) Let $U \subset \mathbb{C}^n$ be an open subset and let $f \colon U \to \mathbb{C}^n$ be a holomorphic map. Furthermore let $P \in U$ be a point. If $\mathrm{D}f_P$ is invertible, then f is a local biholomorphism at P.

Example. The Holomorphic Inverse Function Theorem 32.15 is already interesting and non-trivial if $n = 1$. For example, let $k \in \mathbb{N}$. We consider the map

$$\begin{array}{rcl} f \colon \mathbb{C} \setminus \{0\} & \to & \mathbb{C} \setminus \{0\} \\ z & \mapsto & z^k. \end{array}$$

Note that for every $z \in \mathbb{C} \setminus \{0\}$ we have $f'(z) = k \cdot z^{k-1} \neq 0$. Therefore it follows from the Smooth-Complex Differentiability Proposition 32.3 and the Holomorphic Inverse Function Theorem 32.15 that the above map $f \colon \mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\}$ is a local biholomorphism at every point in $\mathbb{C} \setminus \{0\}$.

Sketch of proof. First note that by the Inverse Function Theorem 19.12 we know that there exists an open neighborhood V of $P \in U \subset \mathbb{C}^n = \mathbb{R}^{2n}$ and an open neighborhood

W of $f(P) \in \mathbb{C}^n = \mathbb{R}^{2n}$ such that $f\colon V \to W$ is a bijection and such that $f^{-1}\colon W \to V$ is smooth. Next note that it follows from the Chain Rule 19.10 that for each $Q \in W$ we have $\mathrm{D}(f^{-1})_P = (\mathrm{D}f_{f^{-1}(Q)})^{-1}$. Since f is holomorphic we know by the Smooth-Complex Differentiability Proposition 32.14 that $\mathrm{D}f_{f^{-1}(Q)}\colon \mathbb{C}^n = \mathbb{R}^{2n} \to \mathbb{C}^n = \mathbb{R}^{2n}$ is a complex linear map. Thus $\mathrm{D}(f^{-1})_P$ is also a complex linear map. It follows from the Smooth-Complex Differentiability Proposition 32.14 that $f^{-1}\colon W \to V$ is holomorphic. ■

32.4. **Complex manifolds.** Given a topological manifold we now introduce the notion of a holomorphic atlas and of a complex manifold. The definition is almost the same as for a smooth atlas and a smooth manifold that we gave on page 541, except that we have to replace "smooth" by "holomorphic".

Definition.

(1) Let M be a $2n$-dimensional topological manifold M. An atlas $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ of charts of type (i), i.e. of charts where each V_i is an open subset of $\mathbb{R}^{2n}$, for M is called holomorphic if for all $i, j \in I$ the transition map

$$\Phi_j \circ \Phi_i^{-1}\colon \underbrace{\Phi_i(U_i \cap U_j)}_{\text{open in } \mathbb{R}^{2n}=\mathbb{C}^n} \to \underbrace{\Phi_j(U_i \cap U_j)}_{\subset \mathbb{R}^{2n}=\mathbb{C}^n}$$

is holomorphic.

(2) We define the maximal holomorphic atlas of a complex manifold the same way as we defined the maximal smooth atlas of a smooth manifold, see page 542. Note that the argument of the Maximal Atlas Existence Proposition 19.17 shows that every holomorphic atlas is contained in a unique maximal holomorphic atlas.

(3) An n-dimensional complex manifold is a pair $(M, \mathcal{A})$ consisting of a $2n$-dimensional topological manifold M, together with a maximal holomorphic atlas for M.

Remark.

(1) As we mentioned above, by the Smooth-Complex Differentiability Proposition 32.3 we know that every holomorphic map from an open subset $U \subset \mathbb{C}^m$ to $\mathbb{C}^n$ is in particular smooth. It follows now easily that every holomorphic atlas is also a smooth atlas. In particular we see that an n-dimensional complex manifold is in particular a $2n$-dimensional smooth manifold.

(2) If M is a complex manifold, then every point admits a chart of type (i) from a smooth atlas, which according to the definitions on page 511 and 545 means, that the boundary ∂M is empty. In particular a compact complex manifold is also closed in the sense of the definitions on page 511 and 545.

Example. Let U be an open subset of $\mathbb{C}^n$. The identity map is an atlas for U and it is evidently a holomorphic atlas. Thus we can view U as an n-dimensional complex manifold.

We move on straight to another set of closely related definitions, which are the holomorphic analogues of the smooth definitions on pages 546 and 543.

Definition.

(1) We say that a map $f\colon M \to N$ between two complex manifolds is holomorphic if f is continuous and if for every chart $\Phi\colon U \to V$ in the holomorphic atlas of M and every chart $\Psi\colon W \to Y$ in the holomorphic atlas of N the map
$$\Phi(f^{-1}(W) \cap U) \xrightarrow{\Psi \circ f \circ \Phi^{-1}} Y$$
is holomorphic.
(2) We say that a map $f\colon M \to N$ between two complex manifolds is a biholomorphism if f is a bijection and if both f and f^{-1} are holomorphic.
(3) We say that a map $f\colon M \to N$ between two complex manifolds is a local biholomorphism if given any $P \in M$ there exists an open neighborhood U of P and an open neighborhood V of $f(P)$ such that $f\colon U \to V$ is a biholomorphism.
(4) We say that two complex atlases for a given topological manifold are equivalent, if the identity map is a biholomorphism between the two complex manifolds corresponding to the complex atlases.
(5) A complex structure on a topological manifold is a choice of an equivalence class of holomorphic atlases.

The next lemma gives us an example of a complex manifold that will play a major role later on.

Lemma 32.16. (Complex Projective Space-is-Complex Manifold Lemma) Let $n \in \mathbb{N}$. On page 255 we introduced the complex projective space
$$\mathbb{C}\mathrm{P}^n \;=\; (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}).$$
For $i = 0, \dots, n$ we consider the map[329]
$$\begin{aligned} \Phi_i\colon \{[z_0 : \cdots : z_n] \in \mathbb{C}\mathrm{P}^n \mid z_i \neq 0\} &\to \mathbb{C}^n \\ [z_0 : \cdots : z_n] &\mapsto \big(\tfrac{z_0}{z_i}, \dots, \tfrac{z_{i-1}}{z_i}, \tfrac{z_{i+1}}{z_i}, \dots, \tfrac{z_n}{z_i}\big). \end{aligned}$$
These maps form a holomorphic atlas for $\mathbb{C}\mathrm{P}^n$ that turn the complex projective space $\mathbb{C}\mathrm{P}^n$ into a compact n-dimensional complex manifold, in particular, as we discussed on page 797, we can view $\mathbb{C}\mathrm{P}^n$ as a closed $2n$-dimensional real smooth manifold.

Convention. We refer to the complex and smooth structure on $\mathbb{C}\mathrm{P}^n$ that we just introduced as the standard complex structure on $\mathbb{C}\mathrm{P}^n$ and as the standard smooth structure on $\mathbb{C}\mathrm{P}^n$.

Proof. In the Projective Spaces-Compact+Hausdorff Proposition 5.30 (see also Exercise 5.44) we saw that each $\mathbb{C}\mathrm{P}^n$ is compact and Hausdorff. As we will show below, $\mathbb{C}\mathrm{P}^n$ admits a finite atlas, thus it follows from Lemma 18.2 that $\mathbb{C}\mathrm{P}^n$ is second-countable. For the remaining statements it is easy to overlook that first one needs to prove the following claim.

Claim 1. If $i \in \{0, \dots, n\}$, then
$$V_i \;:=\; \{[z_0 : \cdots : z_n] \in \mathbb{C}\mathrm{P}^n \mid z_i \neq 0\}$$
is an open subset of $\mathbb{C}\mathrm{P}^n$.

[329] We use the notation from page 256, i.e. given a point $(z_0, \dots, z_n) \in \mathbb{C}^{n+1} \setminus \{0\}$ we denote by $[z_0 : \cdots : z_n]$ the corresponding point in $\mathbb{C}\mathrm{P}^n$.

Proof. The claim is equivalent to showing that the complement $\mathbb{C}\mathrm{P}^n \setminus V_i$ is a closed subset of $\mathbb{C}\mathrm{P}^n$. We note that

$$\mathbb{C}\mathrm{P}^n \setminus V_i \;=\; \text{the image of the map } \begin{array}{rcl} f\colon \mathbb{C}\mathrm{P}^{n-1} & \to & \mathbb{C}\mathrm{P}^n \\ [w_0 : \ldots : w_{n-1}] & \mapsto & [w_0 : \ldots : w_{i-1} : 0 : w_i : \ldots : w_{n-1}]. \end{array}$$

It follows easily from the elementary the Twice Quotient Lemma 5.23 that the map f is continuous. Since $\mathbb{C}\mathrm{P}^{n-1}$ is compact we obtain from the Compact Image Lemma 2.13 that $f(\mathbb{C}\mathrm{P}^{n-1})$ is compact. But since $\mathbb{C}\mathrm{P}^n$ is Hausdorff we obtain from the Compact-Closed Lemma 1.21 (2) that $f(\mathbb{C}\mathrm{P}^{n-1}) = \mathbb{C}\mathrm{P}^n \setminus V_i$ is in fact a closed subset of $\mathbb{C}\mathrm{P}^n$. ⊞

Using this claim it is now straightforward to verify that the maps $\Phi_0, \ldots, \Phi_n$ form an atlas for $\mathbb{C}\mathrm{P}^n$. It remains to prove the following claim.[330]

Claim 2. The atlas is holomorphic.

Proof. First note that for $i \in \{0, \ldots, n\}$ the inverse of the chart Φ_i is given by the map

$$\begin{array}{rcl} \Phi_i^{-1}\colon \mathbb{C}^n & \to & \{[w_0 : \cdots : w_n] \in \mathbb{C}\mathrm{P}^n \,|\, w_i \neq 0\} \\ (w_1, \ldots, w_n) & \mapsto & [w_1 : \cdots : w_i : 1 : w_{i+1} : \cdots : w_n]. \end{array}$$

Now let $i, j \in \{0, \ldots, n\}$. By symmetry it suffices to consider the case $i < j$. Using the above calculation of Φ_i^{-1} one can easily show that the corresponding transition map is given by

$$\begin{array}{rcl} \Phi_j \circ \Phi_i^{-1}\colon \{(w_1, \ldots, w_n) \in \mathbb{C}^n \,|\, w_j \neq 0\} & \to & \{(w_1, \ldots, w_n) \,|\, w_{i+1} \neq 0\} \\ (w_1, \ldots, w_n) & \mapsto & \left(\frac{w_1}{w_j}, \ldots, \frac{w_i}{w_j}, \frac{1}{w_j}, \frac{w_{i+1}}{w_j}, \ldots, \frac{w_{j-1}}{w_j}, \frac{w_{j+1}}{w_j}, \ldots, \frac{w_n}{w_j}\right). \end{array}$$

This map is evidently a biholomorphism. We have thus shown that the given maps $\Phi_0, \ldots, \Phi_n$ form a holomorphic atlas for $\mathbb{C}\mathrm{P}^n$. ■

On page 562 we introduced the notion of a smooth action on a smooth manifold. Not surprisingly we have the following analogue in our present context.

Definition. Let M be a complex manifold which is equipped with an action by a group G. We say that the action is holomorphic if for every $g \in G$ the map $M \to M$ given by $x \mapsto g{\cdot}x$ is holomorphic.

The following proposition is the complex analogue of the Manifold Quotient-by-Group Action Proposition 19.32.

Proposition 32.17. (Complex Manifold Quotient-by-Group Action Proposition) If a group G acts freely, properly[331] and holomorphically on an n-dimensional complex manifold M, then M/G is an $2n$-dimensional topological manifold and there exists a unique complex structure on M/G such that the projection $p\colon M \to M/G$ is a local biholomorphism.

Proof. The proof of the proposition is verbatim the same as the proof of the corresponding statements in the Manifold Quotient-by-Group Action Proposition 19.32 for smooth manifolds. We leave it to the reader to fill in the details. ■

[330] The following claim is very similar to the content of Exercise 19.16.

[331] We refer to page 562 for the definition of a free action and a proper action.

Convention. In the setting of the Complex Manifold Quotient-by-Group Action Proposition 32.17 we will refer to the complex structure on M/G as the standard complex structure on M/G.

Example. We consider the action

$$\begin{array}{rcl} \mathbb{Z} \times \mathbb{C}^n \setminus \{0\} & \to & \mathbb{C}^n \setminus \{0\} \\ (k, (z_1, \ldots, z_n)) & \mapsto & (e^k \cdot z_1, \ldots, e^k \cdot z_n). \end{array}$$

One can easily show that this action is free, proper and holomorphic. Thus we see that the quotient $(\mathbb{C}^n \setminus \{0\})/\mathbb{Z}$ has a standard complex structure. Furthermore it is fairly elementary to verify that the map

$$\begin{array}{rcl} (\mathbb{C}^n \setminus \{0\})/\mathbb{Z} & \to & S^{n-1} \times S^1 \\ z & \mapsto & \left(\frac{z}{\|z\|}, \exp(2\pi \mathrm{i} \cdot \ln(\|z\|))\right) \end{array}$$

is a diffeomorphism. Thus in summary we have shown that $S^{n-1} \times S^1$ admits a complex structure. This complex manifold is called the *Hopf manifold* [**Hopf1948**].

We formulate our next example as a lemma.

Lemma 32.18. Let $v, w \in \mathbb{C}$ be two complex numbers that are linearly independent over $\mathbb{R}$.

(1) The action

$$\begin{array}{rcl} (\mathbb{Z} \cdot v + \mathbb{Z} \cdot w) \times \mathbb{C} & \to & \mathbb{C} \\ ((m \cdot v + n \cdot w), z) & \mapsto & z + m \cdot v + n \cdot w \end{array}$$

is free, proper and holomorphic.

(2) The quotient $T(v, w) := \mathbb{C}/(\mathbb{Z} \cdot v + \mathbb{Z} \cdot w)$ is a 2-dimensional topological manifold and it admits a unique complex structure which has the property that the natural projection $\mathbb{C} \to T(v, w) = \mathbb{C}/(\mathbb{Z} \cdot v + \mathbb{Z} \cdot w)$ is a local biholomorphism.

(3) The complex manifold $T(v, w) = \mathbb{C}/(\mathbb{Z} \cdot v + \mathbb{Z} \cdot w)$ is compact and, viewed as a smooth manifold, it is diffeomorphic to $S^1 \times S^1$.

(4) Let $\widetilde{v}, \widetilde{w}$ be two complex numbers that are linearly independent over $\mathbb{R}$. If there exists an $r \in \mathbb{C} \setminus \{0\}$ such that $r \cdot (\mathbb{Z} \cdot v + \mathbb{Z} \cdot w) = \mathbb{Z} \cdot \widetilde{v} + \mathbb{Z} \cdot \widetilde{w}$, then the complex manifolds $T(v, w)$ and $T(\widetilde{v}, \widetilde{w})$ are biholomorphic.

Remark. In Proposition 63.1 we will see that the converse to Lemma 32.18 (4) holds. More precisely, we will see that if $T(v, w)$ and $T(\widetilde{v}, \widetilde{w})$ are biholomorphic, then there exists an $r \in \mathbb{C} \setminus \{0\}$ such that $r \cdot (\mathbb{Z} \cdot v + \mathbb{Z} \cdot w) = \mathbb{Z} \cdot \widetilde{v} + \mathbb{Z} \cdot \widetilde{w}$.

Proof.

(1) In Exercise 19.34 we showed that the action is proper. It is clear that the action is free and holomorphic.

(2) This statement follows from (1) together with the Complex Manifold Quotient-by-Group Action Proposition 32.17.

(3) We consider the map

$$\begin{array}{rcl} \mathbb{C}/(\mathbb{Z} \cdot v + \mathbb{Z} \cdot w) & \to & S^1 \times S^1 \\ [r \cdot v + s \cdot w] & \to & (\exp(2\pi \mathrm{i} s), \exp(2\pi \mathrm{i} t)). \end{array}$$

It follows from the Smooth Map-Descends-to-Quotient Corollary 19.33 that the map is a local diffeomorphism. Since v and w are linearly independent one sees that the map is a bijection. It follows from the Smooth Pasting Proposition 19.23 (2) that the map is in fact a diffeomorphism. Since $S^1 \times S^1$ is compact we see that $T(v, w)$ is also compact.

(4) Let $\widetilde{v}, \widetilde{w}$ be two complex numbers that are linearly independent over $\mathbb{R}$. We assume that there exists an $r \in \mathbb{C} \setminus \{0\}$ such that $r \cdot (\mathbb{Z} \cdot v + \mathbb{Z} \cdot w) = \mathbb{Z} \cdot \widetilde{v} + \mathbb{Z} \cdot \widetilde{w}$. In this case we obtain the following commutative diagram:

$$\begin{array}{ccc} \mathbb{C} & \xrightarrow{z \mapsto r \cdot z} & \mathbb{C} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle \widetilde{p}} \\ T(v, w) & \xrightarrow{[z] \mapsto [r \cdot z]} & T(\widetilde{v}, \widetilde{w}). \end{array}$$

Note that our hypothesis shows that bottom horizontal map is defined and a bijection. The top horizontal map is of course a biholomorphism. Since the vertical maps are local biholomorphisms we see that the bottom horizontal map is a bijection and a local biholomorphism. In other words, it is a biholomorphism. ■

We continue our discussion of complex manifolds with a pleasing proposition.

Proposition 32.19. Let M be a compact 1-dimensional complex manifold. Then any holomorphic function $f \colon M \to \mathbb{C}$ is constant.

Proof. We provide the proof of the proposition in Exercise 32.2. ■

Remark. If $M = T(v, w) = \mathbb{C}/(\mathbb{Z} \cdot v \oplus \mathbb{Z} \cdot w)$, then we can also give another, arguably easier proof of the conclusion of Proposition 32.19. Indeed, let $f \colon \mathbb{C}/(\mathbb{Z} \cdot v \oplus \mathbb{Z} \cdot w) \to \mathbb{C}$ be a holomorphic function. Since $\mathbb{C}/(\mathbb{Z} \cdot v \oplus \mathbb{Z} \cdot w) \cong S^1 \times S^1$ is compact we obtain from the Compact Image Lemma 2.13 that the function f is bounded. As usual we denote by $p \colon \mathbb{C} \to \mathbb{C}/(\mathbb{Z} \cdot v \oplus \mathbb{Z} \cdot w)$ the projection . Recall that p is holomorphic. Thus the composition $f \circ p \colon \mathbb{C} \to \mathbb{C}$ is a bounded holomorphic function. We deduce from the Liouville Theorem 32.6 that $f \circ p$ is constant. Since p is surjective it follows that f is also constant.

Next we introduce the notion of a submanifold of a complex manifold. The definition is almost verbatim the same as the definition of a submanifold of a smooth manifold on page 550. The only difference is that we do not need to worry about boundary points.

Definition. Let M be an n-dimensional complex manifold.

(1) We say a subset $N \subset M$ is a k-dimensional complex submanifold if given any $P \in N$ there exists a chart $\Phi \colon U \to V$ in the maximal complex atlas for M and P such that

$$\Phi(U \cap N) \;=\; V \cap \{(0, \ldots, 0, z_1, \ldots, z_k) \,|\, z_i \in \mathbb{C}\},$$

Any collection of charts covering N is called a holomorphic submanifold atlas.

(2) We say a submanifold N is proper if N is a closed subset of M.

Example. Let $n \in \mathbb{N}$ and let $k \in \{0, \dots, n\}$. Using a mild modification of the charts from the Complex Projective Space-is-Complex Manifold Lemma 32.16 one can easily show that

$$\{[z_0 : \cdots : z_k : 0 : \cdots : 0] \in \mathbb{C}\mathrm{P}^n \mid (z_0, \dots, z_k) \in \mathbb{C}^{k+1} \setminus \{0\}\}$$

is a submanifold of the complex manifold $\mathbb{C}\mathrm{P}^n$.

The following lemma is an analogue of the Submanifold Smooth Structure Lemma 19.24.

Lemma 32.20. (Submanifold Complex Structure Lemma) Let M be a complex manifold and let N be a complex submanifold of M. The collection of all submanifold charts of M gives naturally rise to a holomorphic atlas for N which we refer to as the standard complex structure on the submanifold. The standard complex structure has the following properties:

(1) The inclusion map $N \to M$ is a holomorphic map.
(2) If we start out with some submanifold atlas for M, then this gives rise to the same complex structure on N.
(3) Let $f\colon W \to M$ be a holomorphic map. If $f(W) \subset N$, then $f\colon W \to N$ is also holomorphic.

Proof. The proof is basically identical to the proof of the Submanifold Smooth Structure Lemma 19.24. We leave it to the reader to make the few necessary modifications. ■

The following theorem is the complex analogue of the Regular Value Theorem 26.4. As in the real case, it is a machine for providing examples of complex (sub-) manifolds.

Theorem 32.21. (Regular Value Theorem for Complex Manifolds) Let M be an m-dimensional complex manifold and let N be an n-dimensional complex manifold. Furthermore let $f\colon M \to N$ be a holomorphic map and let $s \in N$ be a regular value of f.

(1) The preimage $X := f^{-1}(s)$ is an $(m-n)$-dimensional complex submanifold of M.
(2) The intersection of X with any compact set of M is compact. In particular, if M is compact, then X is also compact.

Proof. The proof is almost identical to the proof of the "real" Regular Value Theorem 26.4. The main difference is that we need to replace the Inverse Function Theorem 19.12 by the Holomorphic Inverse Function Theorem 32.15. We refer to [**Huy2005**, p. 11 and p. 58] for some more details. ■

Examples.

(1) Let $n \in \mathbb{N}$. By basically the same argument as in the proof of the Matrix Group-Smooth Manifold Proposition 26.5 one can show that

$$\begin{array}{rcl} \mathrm{M}(n \times n, \mathbb{C}) & \to & \mathbb{C} \\ A & \mapsto & \det(A) \end{array}$$

is holomorphic and that $1 \in \mathbb{C}$ is a regular value. It follows from the Regular Value Theorem 32.21 for Complex Manifolds that $\mathrm{SL}(n, \mathbb{C})$ is an (n^2-1)-dimensional complex submanifold of $\mathrm{M}(n \times n, \mathbb{C}) = \mathbb{C}^{n^2}$. In particular by the Submanifold Complex Structure Lemma 32.20 we can view $\mathrm{SL}(n, \mathbb{C})$ as an (n^2-1)-dimensional complex submanifold.

(2) Let $n \in \mathbb{Z}$. In Exercise 32.12 we will use the Regular Value Theorem 32.21 for Complex Manifolds to show that $\{[x:y:z] \in \mathbb{C}\mathrm{P}^2 \,|\, x^n + y^n + z^n = 0\}$ is a compact 1-dimensional complex manifold.

32.5. The natural orientation of a complex manifold.

Lemma 32.22. (Complex Vector Space-Orientation Lemma)

(1) Let V be an n-dimensional complex vector space.
   (a) If $(v_1, \dots, v_n)$ is a basis of V viewed as a complex vector space, then the set $(v_1, \mathrm{i}v_1, \dots, v_n, \mathrm{i}v_n)$ is a basis of V viewed as a real vector space.
   (b) If $(v_1, \dots, v_n)$ and $(w_1, \dots, w_n)$ are two bases of V as a complex vector space, then the bases $(v_1, \mathrm{i}v_1, \dots, v_n, \mathrm{i}v_n)$ and $(w_1, \mathrm{i}w_1, \dots, w_n, \mathrm{i}w_n)$ are equivalent in the sense of page 668.

(2) Let $f\colon V \to W$ be an isomorphism of n-dimensional complex vector spaces. If we equip V and W, viewed as real vector spaces, with the orientation from (1), then $f\colon V \to W$ is an orientation-preserving isomorphism.

Definition. Given a finite-dimensional complex vector space we refer to the orientation introduced in the Complex Vector Space-Orientation Lemma 32.22 (1) as the natural orientation.

Example. Let $n \in \mathbb{N}_0$. If we make the usual identification $\mathbb{C}^n = (\mathbb{R}^2)^n = \mathbb{R}^{2n}$, then the corresponding natural orientation on $\mathbb{C}^n = \mathbb{R}^{2n}$ agrees with the standard orientation.

Proof.

(1) Let $(v_1, \dots, v_n)$ be a basis of V as a complex vector space. One can easily verify that $(v_1, \mathrm{i}v_1, \dots, v_n, \mathrm{i}v_n)$ is a generating set over $\mathbb{R}$ and that it is linearly independent over $\mathbb{R}$. This concludes the proof of (a).

We turn to the proof of (b). Let $(v_1, \dots, v_n)$ and $(w_1, \dots, w_n)$ be two bases of V as a complex vector space. We denote by $A \in \mathrm{GL}(n \times n, \mathbb{C})$ the transition matrix as defined on page 668. We write $A = B + \mathrm{i}C$, where $B, C \in \mathrm{M}(n \times n, \mathbb{R})$. We consider the bases

$$\begin{aligned} X &:= (v_1, \mathrm{i}v_1, \dots, v_n, \mathrm{i}v_n) \quad \text{and} \quad Y := (w_1, \mathrm{i}w_1, \dots, w_n, \mathrm{i}w_n) \\ \widetilde{X} &:= (v_1, \dots, v_n, \mathrm{i}v_1, \dots, \mathrm{i}v_n) \quad \text{and} \quad \widetilde{Y} := (w_1, \dots, w_n, \mathrm{i}w_1, \dots, \mathrm{i}w_n). \end{aligned}$$

We now calculate the determinant of the transition matrix $P_{X,Y}$ from X to Y:

$$\begin{aligned} \det(P_{X,Y}) &\overset{\text{see the Transition Matrix Lemma 25.1}}{=} \det(P_{\widetilde{X},X}) \cdot \det(P_{\widetilde{X},\widetilde{Y}}) \cdot \det(P_{\widetilde{Y},Y}) \overset{\text{since } P_{\widetilde{X},X} = P_{\widetilde{Y},Y}}{=} \underbrace{\det(P_{\widetilde{X},X})^2}_{=\pm 1} \cdot \det(P_{\widetilde{X},\widetilde{Y}}) \overset{\text{follows from Lemma 32.1}}{=} \det(P_{\widetilde{X},\widetilde{Y}}) \\ &= \det \begin{pmatrix} B & -C \\ C & B \end{pmatrix} \underset{\text{add } i \text{ times bottom to the top}}{=} \det \begin{pmatrix} B+\mathrm{i}C & -C+\mathrm{i}B \\ C & B \end{pmatrix} \underset{\text{subtract } i \text{ times left from the right}}{=} \det \begin{pmatrix} B+\mathrm{i}C & 0 \\ C & B-\mathrm{i}C \end{pmatrix} \\ &= \det(B+\mathrm{i}C) \cdot \det(B-\mathrm{i}C) = \det(B+\mathrm{i}C) \cdot \overline{\det(B+\mathrm{i}C)} \\ &= |\det(B+\mathrm{i}C)|^2 > 0. \end{aligned}$$

(2) This statement follows immediately from (1). ∎

The following proposition says that complex manifolds admit a natural orientation, in particular they are orientable.

Proposition 32.23. (Complex Manifold-Orientation Proposition)

(1) Let M be an n-dimensional complex manifold.
   (a) Given any $P \in M$ we can use charts from the holomorphic atlas to equip $\mathrm{T}_P M$ naturally with the structure of a complex n-dimensional vector space.
   (b) If we equip each complex vector space $\mathrm{T}_P M$ with the corresponding natural orientation, then these orientations define an orientation on M, viewed as a $2n$-dimensional real smooth manifold. We refer to this orientation as the natural orientation of the complex manifold M.

(2) If $f\colon M \to N$ is a holomorphic map between two complex manifolds, then for each $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ is a complex linear map.

(3) If $f\colon M \to N$ is a local biholomorphism between two complex manifolds, then f is an orientation-preserving diffeomorphism between M and N, viewed as oriented smooth manifolds.

Sketch of a proof.

(1) (a) Let M be an n-dimensional complex manifold and let $P \in M$. We pick a chart $\Phi\colon U \to V$ from the holomorphic atlas around P. We get an induced isomorphism $\mathrm{D}\Phi_P\colon \mathrm{T}_P M \to \mathrm{T}_P V = \mathbb{C}^n$. We use this isomorphism to equip $\mathrm{T}_P M$ with the structure of a complex vector space. Since Φ comes from a holomorphic atlas one obtains easily from the Smooth-Complex Differentiability Proposition 32.14 , see Exercise 32.8, that this complex vector space structure does not depend on the choice of the chart Φ.
   (b) This statement follows easily from the definitions. We leave it to the reader to fill in the details.

(2) This statement follows fairly easily from the definitions and the Smooth-Complex Differentiability Proposition 32.14. We outsource the details to Exercise 32.11.

(3) The proof is identical to the proof of (1b). ■

Definition. Let M be an n-dimensional complex manifold. We refer to the orientation on the $2n$-dimensional smooth manifold M that is provided by the Complex Manifold-Orientation Proposition 32.23 as the standard orientation.

Example. In the Complex Projective Space-is-Complex Manifold Lemma 32.16 we equipped $\mathbb{C}\mathrm{P}^n$ with a complex structure. We refer to the corresponding orientation on the $2n$-dimensional smooth manifold $\mathbb{C}\mathrm{P}^n$ as the standard orientation on $\mathbb{C}\mathrm{P}^n$.

We continue with the following corollary to the Complex Manifold-Orientation Proposition 32.23.

Corollary 32.24. The Klein bottle and the real projective plane $\mathbb{R}\mathrm{P}^2$ do not admit the structure of a complex manifold.

Proof. In the Surface Non-Orientability Lemma 25.20 we showed that neither the Klein bottle nor the real projective plane $\mathbb{R}\mathrm{P}^2$ are orientable. This is in contrast to the fact, shown in the Complex Manifold-Orientation Proposition 32.23, that complex manifolds are orientable. ■

As we had already pointed out on page 258, the one-dimensional projective space $\mathbb{C}\mathrm{P}^1$ is homeomorphic to S^2. This shows that S^2 can be viewed as a 1-dimensional complex manifold. We had just seen that the 2-sphere and the torus are complex manifolds and we saw that non-orientable smooth manifolds cannot be complex manifolds. The following question now arises:

Question 32.25. Let $g \geq 2$. Does the surface of genus g have the structure of a complex manifold?

We will discuss this question in Proposition 66.2.

Remark. It is often very hard to determine whether or not a given orientable even-dimensional smooth manifold admits that a complex structure. For example, Armand Borel and Jean-Pierre Serre [**BoS1953**][332] showed in 1953 that for $n \neq 2, 6$ the n-dimensional sphere S^n cannot be a complex manifold. On the other hand it is still an open question whether S^6 admits a complex structure.

Exercises for Chapter 32.

Exercise 32.1. Use the Power Series Expansion Theorem 32.5 (1) to show that every bounded holomorphic function $f\colon \mathbb{C} \to \mathbb{C}$ is constant.

Exercise 32.2. Let M be a compact connected 1-dimensional complex manifold. Show that any holomorphic function $f\colon M \to \mathbb{C}^n$ is constant.
Hint. Use the Maximum Principle, i.e. use Theorem 32.10.

Exercise 32.3. Let $f\colon \mathbb{C} \to \mathbb{C}$ be a holomorphic non-constant function. Use Liouville's Theorem 32.6 to show that $f(\mathbb{C})$ is dense in $\mathbb{C}$.

Exercise 32.4. Use Liouville's Theorem 32.6 to show that every complex polynomial of degree ≥ 1 has a zero.

Exercise 32.5. Let $U \subset \mathbb{C}$ be an open connected subset and let $f, g\colon U \to \mathbb{C}$ be two holomorphic functions. Suppose that there exists a $z_0 \in U$ such that $f^{(k)}(z_0) = g^{(k)}(z_0)$ for all $k \in \mathbb{N}_0$. Use the Locally-a-Power Theorem 32.8 to show that $f = g$ on all of U.

Exercise 32.6. Let U be an open subset of $\mathbb{C}$, let $f\colon U \to \mathbb{C}$ be a holomorphic function and let $V \subset U$ is a connected open subset such that $f|_V$ is not constant. Show that $f(V)$ is an open subset of $\mathbb{C}$.
Hint. Use the Locally-a-Power Theorem 32.8 and use the Inverse Function Theorem 19.12.

Exercise 32.7. Let U be an open connected subset of $\mathbb{C}$ and let $f\colon U \to \mathbb{C}$ be a holomorphic function. Show that if the function $|f|\colon U \to \mathbb{R}_{\geq 0}$ has a local maximum, then f is constant.
Hint. Use Proposition 32.9.

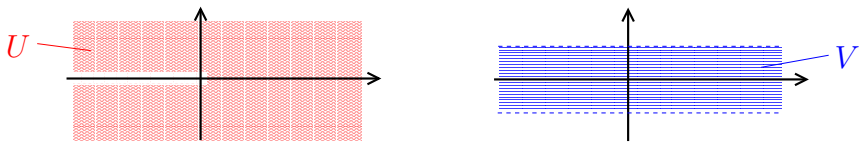
Exercise 32.8. Let $U \subset \mathbb{C}^n$ be an open set and let $f\colon U \to \mathbb{C}^m$ be a holomorphic map. Show that given any $P \in U$ the differential $\mathrm{D}f_P$ lies in $\mathrm{M}(m \times n, \mathbb{C}) \subset \mathrm{M}(2m \times 2n, \mathbb{R})$.

[332] Armand Borel (1923–2003) was a Swiss mathematician, Jean-Pierre Serre (*1926) is a French mathematician who was awarded a Fields medal in 1954.

Exercise 32.9.

(a) We view S^2 as a subspace of $\mathbb{C}\times\mathbb{R}=\mathbb{R}^3$. We consider the maps

$$\begin{array}{rcl}\Phi_+\colon S^2\setminus\{(0+0\mathrm{i},1)\} & \to & \mathbb{C}\\ (z,t) & \mapsto & \frac{z}{1-t}\end{array}\qquad\text{and}\qquad\begin{array}{rcl}\Phi_-\colon S^2\setminus\{(0+0\mathrm{i},-1)\} & \to & \mathbb{C}\\ (z,t) & \mapsto & \frac{\overline{z}}{1+t}.\end{array}$$



Note that Φ_+ is the stereographic projection from the North Pole $(0+0\mathrm{i},1)$ and that Φ_- is the stereographic projection the South Pole $(0+0\mathrm{i},-1)$ composed with complex conjugation. In Lemma 2.18 we showed that these two maps are homeomorphisms. Show that these two charts define a holomorphic atlas for S^2. We refer to this complex structure on S^2 as the *standard complex structure on* S^2.

(b) In Lemmas 2.18 and 5.32 we gave an explicit homeomorphism $S^2\to\mathbb{C}\mathrm{P}^1$. Show that this map is a biholomorphism between the complex manifolds S^2 and $\mathbb{C}\mathrm{P}^1$.

Exercise 32.10. Show, without using the Riemann Mapping Theorem 32.12, that the complex manifolds

$$\begin{array}{rcl}U & := & \{z\in\mathbb{C}\,|\,\mathrm{Re}(z)>0 \text{ or } \mathrm{Im}(z)\neq 0\}\\ V & := & \{z\in\mathbb{C}\,|\,\mathrm{Im}(z)\in(-\pi,\pi)\}\end{array}$$

are biholomorphic.

Exercise 32.11. Let $f\colon M\to N$ is a holomorphic map between two complex manifolds. Show that for each $P\in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_PM\to\mathrm{T}_{f(P)}N$ is a complex linear map.

Exercise 32.12. Let $n\in\mathbb{Z}$. Show that $\{[x:y:z]\in\mathbb{C}\mathrm{P}^2\,|\,x^n+y^n+z^n=0\}$ is a compact 1-dimensional complex submanifold of $\mathbb{C}\mathrm{P}^2$.

Exercise 32.13. Let $n\in\mathbb{N}$. Let $\mathbb{C}\mathrm{P}^n=(\mathbb{C}^{n+1}\setminus\{0\})/(\mathbb{C}\setminus\{0\})$ be the complex projective space.

(a) Show that

$$M \;:=\; \{([z],v)\in\mathbb{C}\mathrm{P}^n\times\mathbb{C}^{n+1}\,|\,v\in\mathbb{C}\cdot z\}$$

is a holomorphic submanifold of $\mathbb{C}\mathrm{P}^n\times\mathbb{C}^{n+1}$.

(b) Show that the map

$$\begin{array}{rcl}\pi\colon M & \to & \mathbb{C}^{n+1}\\ ([z],v) & \mapsto & v\end{array}$$

is holomorphic and show that $\pi^{-1}(\mathbb{C}^{n+1}\setminus\{0\})\to\mathbb{C}^{n+1}\setminus\{0\}$ is a biholomorphism.

Remark. The complex manifold M is called the *blow up of* $\mathbb{C}^{n+1}$ *at the origin.*

Exercise 32.14. Let $q(z)=$ be a non-constant complex polynomial. Show that the map

$$\begin{array}{rcl}\mathbb{C}\mathrm{P}^1 & \to & \mathbb{C}\mathrm{P}^1\\ [z:w] & \mapsto & \begin{cases}[q(a):1], & \text{if } [z:w]=[a:1] \text{ for some } a\in\mathbb{C},\\ [1:0], & \text{if } [z:w]=[1:0]\end{cases}\end{array}$$

is holomorphic.

Remark. On page 705 we showed that this map is smooth.

Exercise 32.15. We refer to the category $\mathcal{CplxMfd}$ with

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{CplxMfd}) & := & \text{all complex manifolds,} \\ \mathrm{Mor}(X,Y) & := & \text{all holomorphic maps from } X \text{ to } Y, \end{array}$$

with the usual composition of maps as the *category of complex manifolds*. Furthermore we define the category $\mathcal{PCplxMfd}$ of pointed complex manifolds in the obvious way. Show that the maps

$$\begin{array}{rcl} (M,P) & \mapsto & \mathrm{T}_P M \\ (f\colon (M,Q) \to (N,Q)) & \mapsto & (\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_Q N) \end{array}$$

define a covariant functor from the category $\mathcal{PCplxMfd}$ of pointed complex manifolds to the category $\mathcal{Vec}_{\mathbb{C}}$ of $\mathbb{C}$-vector spaces.

Remark. This exercise should be viewed as the complex analogue of the Tangent Space-Functor Proposition 23.10.

Part IV

Differential topology

In the last part of the lecture notes we introduced topological and smooth manifolds and we introduced many of the essential notions and we formulated and proved many of the basic theorems. In this part of the lecture notes we intensify our study of smooth manifolds. As the name "differential topology" suggests, we are interested in the topological properties of smooth manifolds. We will start out with a long discussion of smooth homotopies on smooth manifolds. Afterwards we will introduce the degree of a smooth map between smooth manifolds. This notion has many applications, for example it allows us to prove the Hairy Ball Theorem 38.12 and the Borsuk-Ulam 39.8.

33. Smooth homotopies

In this chapter we will introduce the notion of smooth homotopies, smooth isotopies and diffeotopies. Furthermore, in this and the following chapter we will discuss some basic properties and many examples.

33.1. **Smooth homotopies.** Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. Suppose we are given two smooth maps $f_0, f_1 \colon M \to N$. On page 420 we defined a homotopy between f_0 and f_1 to be a map $F \colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$. On many occasions one feels much happier if one actually has a "smooth homotopy". To make sense of the notion of a smooth homotopy we need to recall some concepts we introduced earlier.

(1) If M is a smooth manifold with empty boundary and if $a < b$ are two real numbers, then by the Smooth Manifold Product Proposition 19.31 (1) we can equip $M \times [a,b]$ with a natural structure of an $(m+1)$-dimensional smooth manifold.
(2) More generally, if M is any smooth manifold, possibly with non-empty boundary, then by the Smooth Manifold Product Proposition 20.6 we can view $M \times [a,b]$ as an $(m+1)$-dimensional smooth manifold with corner $\angle(M \times [a,b]) = \partial M \times \{a,b\}$.

Either way, by the definitions on page 546 and on page 581 we now have a notion of a map $F \colon M \times [a,b] \to N$ to be smooth.

For people who happen to be allergic to smooth manifolds with corner, the following lemma often makes it possible to avoid dealing with the notion of smooth maps defined on smooth manifolds with corner.

Lemma 33.1. Let M and N be smooth manifolds and let $F \colon M \times [a,b] \to N$ be a map.

(1) Let I be an interval with $[a,b] \subset I$. (We allow $I = [a,b]$).
(2) Let $\widetilde{M}$ be a smooth manifold that contains M as a submanifold. (We allow $\widetilde{M} = M$).

If there exists a smooth map[333] $G \colon \widetilde{M} \times I \to N$ such that the restriction of G to the subset $M \times [a,b]$ equals F, then $F \colon M \times [a,b] \to N$ is also smooth.

Proof. This lemma follows immediately from Lemmas 20.3 and 20.7. ∎

After this preamble we now introduce the main protagonist of this chapter.

Definition. Let M and N be smooth manifolds.

(1) A smooth homotopy is a smooth map $F \colon M \times [0,1] \to N$.
(2) We say that two smooth maps $f_0, f_1 \colon M \to N$ are smoothly homotopic if there exists a smooth homotopy $F \colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$.[334]

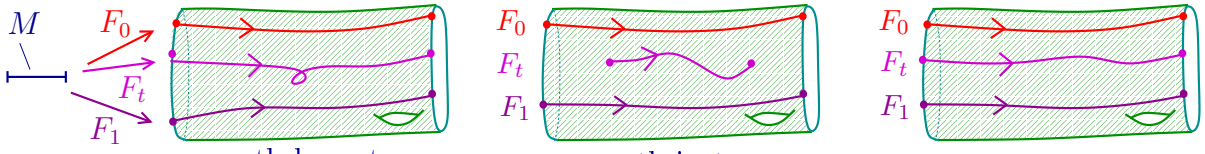
There are various special types of smooth homotopies which we will now introduce.

[333] If either I is an open interval, or if $\partial \widetilde{M} = \varnothing$, then it follows from the Smooth Manifold Product Proposition 19.31 (1) that we can treat $\widetilde{M} \times I$ as a smooth manifold without corner.

[334] Recall that given a homotopy $F \colon X \times [a,b] \to Y$ and $t \in [a,b]$ we denote by $F_t \colon X \to Y$ the map that is given by $x \mapsto F(x,t)$.

Definition. Let M and N be smooth manifolds.

(1) A smooth isotopy of M in N is a smooth map



$$F\colon M \times [0,1] \;\to\; N$$

such that for each $t \in [0,1]$ the map $F_t\colon M \to N$ is a smooth embedding.[335]

(2) We say a smooth isotopy $F\colon M \times [0,1] \to N$ is proper if each F_t is a proper smooth embedding[336] *and* if the map $F\colon M \times [0,1] \to N$ is proper in the sense of the definition on page 180, i.e. the preimage of every compact subset of N is a compact subset of $M \times [0,1]$.

(3) We say that two (proper) smooth embeddings $f_0, f_1\colon M \to N$ are (properly) smoothly isotopic if there exists a (proper) smooth isotopy $F\colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$.

If each F_t is a diffeomorphism, then we refer to a smooth isotopy as a diffeotopy and we say "diffeotopic" instead of "smoothly isotopic".

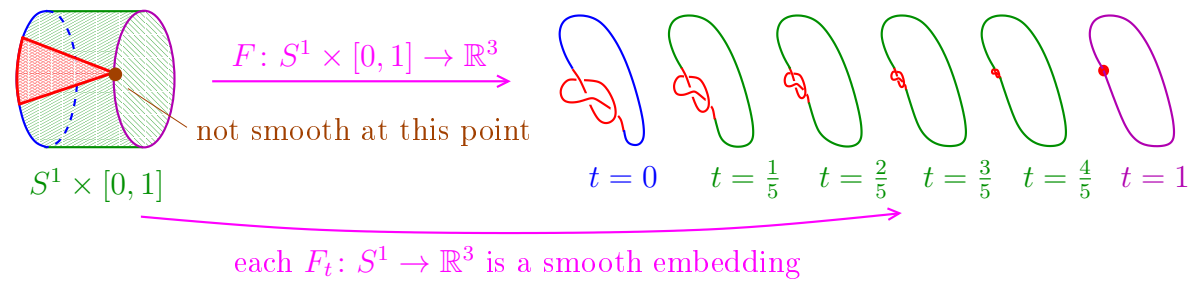
smooth homotopy but not a smooth isotopy

smooth isotopy but not a proper smooth isotopy

proper smooth isotopy

Example. We will soon give many examples of smooth isotopies. At this point it is perhaps better to give a non-example. More precisely, we consider the map $F\colon S^1 \times [0,1] \to \mathbb{R}^3$ that is sketched in the figure below. This map has the property that for each $t \in [0,1]$ the map $F_t\colon S^1 \to \mathbb{R}^3$ is a smooth embedding. But the map $F\colon S^1 \times [0,1] \to \mathbb{R}^3$ is not smooth. Thus this map is not a smooth isotopy.

Remark. The term "diffeotopic" is (alas!) used differently by different authors. Our definition agrees with the definition given in most textbooks, see e.g. [**Wall2016**, p. 49] and [**BJ1982**, Definition 9.3]. But it differs from the definition provided in [**Hirs1976**, Chapter 8], there the map on $M \times [0,1]$ only needs to be continuous, but each F_t needs to be a diffeomorphism. As we just saw in the previous example, this is a weaker condition.



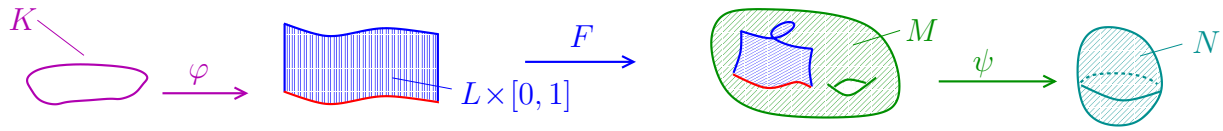
---

[335] Recall that by the definition on page 652 a map $f\colon M \to N$ between smooth manifolds is a *smooth embedding* if it is a homeomorphism onto its image, if it is smooth and if the following statements hold:

(1) For each $P \in M$ the map $\mathrm{D}\varphi_P\colon \mathrm{T}_P M \to \mathrm{T}_{\varphi(P)} N$ is a monomorphism.
(2) For each $P \in M \setminus \partial M$ we have $\varphi(P) \in N \setminus \partial N$.
(3) For each $P \in \partial M$ with $\varphi(P) \in \partial N$ the image $\mathrm{D}\varphi_P(\mathrm{T}_P M)$ is not contained in $\mathrm{T}_{\varphi(P)}(\partial N)$.
(4) For every component C of ∂M we have either $\varphi(C) \subset \partial N$ or $\varphi(C) \subset N \setminus \partial N$.

[336] By the definition on page 650 a smooth embedding is called *proper* if furthermore the following hold:

(5) $f^{-1}(\partial N) = \partial M$,
(6) $f(M)$ is a closed subset of N.



The following elementary lemma says in particular that one can precompose and postcompose smooth isotopies by smooth maps. It can be viewed as the analogue of Lemmas 14.5 (2).

Lemma 33.2. Let K, L, M and N be smooth manifolds. If $F\colon L \times [0,1] \to M$ is a smooth homotopy and if $\varphi\colon K \to L$ and $\psi\colon M \to N$ are smooth maps, then the maps

$$\begin{array}{rcl} K \times [0,1] & \to & M \\ (x,t) & \mapsto & F(\varphi(x),t) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} L \times [0,1] & \to & N \\ (x,t) & \mapsto & \psi(F(x,t)) \end{array}$$

are also smooth homotopies. If φ and ψ are diffeomorphisms, then a (proper) smooth isotopy (diffeotopy) $F\colon L \times [0,1] \to M$ becomes again a (proper) smooth isotopy (diffeotopy).

Proof. All of the statements are basically trivial, except that one needs to argue why the two maps $L \times [0,1] \to M$ and $K \times [0,1] \to N$ are smooth. Note that the map $L \times [0,1] \to M$ is the composition of the maps

$$K \times [0,1] \xrightarrow{\varphi \times \mathrm{id}_{[0,1]}} L \times [0,1] \xrightarrow{F} M.$$

It follows from the Smooth Manifold Product Proposition 20.6 that the map to the left is smooth. Thus the given map is the composition of two smooth maps between smooth manifolds with corner. Therefore it follows from Lemma 20.3 that it is smooth. Finally note that the map $K \times [0,1] \to N$ is precisely the map $\psi \circ F$, thus it is smooth by Lemma 20.3. ∎

In Lemma 14.5 (1) we saw that being homotopic is an equivalence relation. The analogous statement also holds in the smooth context.

Proposition 33.3. (Smooth Isotopy Transitivity Proposition) Let M and N be smooth manifolds.

(1) For maps $M \to N$ being "smoothly homotopic", being "smoothly (properly) isotopic" and being "diffeotopic" is an equivalence relation.
(2) If $A \subset M$ is a subset, then the statements in (1) also hold "rel A".[337]

[337] Recall that according to the definition on page 419 we say that a map $F\colon X \times [0,1] \to Y$ that is a *homotopy rel* A if for all $x \in A$ and $s, t \in [0,1]$ we have $F(x,s) = F(x,t)$.

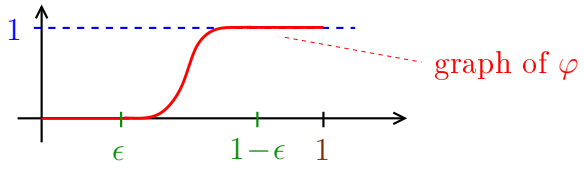
At first glance the Smooth Isotopy Transitivity Proposition 33.3 might appear trivial, but the proof of the transitivity statement is technically slightly involved. The reader who is happy to swallow the Smooth Isotopy Transitivity Proposition 33.3 as it is, can also press the fast-forward button and move on to the next section.
Before we provide the proof of the Smooth Isotopy Transitivity Proposition 33.3 we need to make a few preparations. We start out with the following definition.

Definition. Let X and Y be topological spaces. We say a homotopy $F\colon X \times [0,1] \to Y$ is trivial near the ends if there exists an $\epsilon > 0$ such that for all $P \in X$ and all $t \in [0,\epsilon]$ we have $F(P,t) = F(P,0)$ and $F(P,1-t) = F(P,1)$.

The proof of the Smooth Isotopy Transitivity Proposition 33.3 rests on the following two lemmas.

Lemma 33.4. (Trivial-Near-The-Ends-Lemma) [338] Let M and N be smooth manifolds, let $F\colon M \times [0,1] \to N$ be a smooth homotopy and let $\epsilon \in (0, \frac{1}{2})$. There exists a smooth homotopy $G\colon M \times [0,1] \to N$ with the following properties:

(1) We have $G_0 = F_0$ and $G_1 = F_1$.
(2) For every $t \in [0,\epsilon)$ we have $G_t = F_0$ and for every $t \in [1-\epsilon, 1]$ we have $G_t = F_1$. In particular the smooth homotopy G is trivial near the ends.
(3) For each $s \in [0,1]$ there exists a $t \in [0,1]$ with $G_s = F_t$.



Furthermore, if F is a proper smooth homotopy or a diffeotopy, then so is G.

Proof of the Trivial-Near-The-Ends-Lemma 33.4. Let M and N be smooth manifolds and let $F\colon M \times [0,1] \to N$ be a smooth homotopy. Using the Smooth Transition Function Lemma 19.4 one can easily show that there exists a smooth map $\varphi\colon [0,1] \to [0,1]$ such that $\varphi(0) = 0$, $\varphi(1) = 1$, $\varphi(t) = 0$ for all $t \in [0,\epsilon]$ and $\varphi(t) = 1$ for all $t \in [1-\epsilon, 1]$. It follows from Lemmas 20.3 and 20.7 that the map

$$\begin{array}{rcl} F \circ (\mathrm{id}_M \times \varphi)\colon M \times [0,1] & \to & N \\ (x,y) & \mapsto & (x,t) \mapsto F(x,\varphi(t)) \end{array}$$

is smooth. It is clear that this map has the desired Properties (1), (2) and (3).

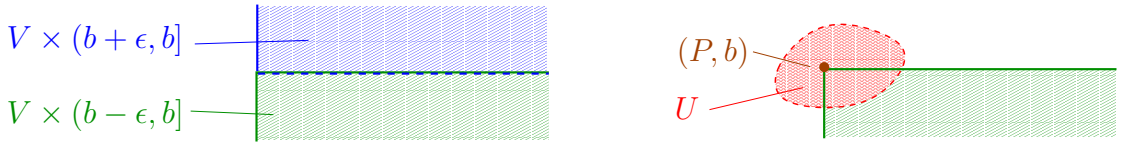
Finally note that if F is a proper smooth homotopy (diffeotopy), then it follows from Property (3) that G is also a proper smooth homotopy (diffeotopy). ■

We also need the following variation on the Homotopy Stacking Lemma 14.3.

[338] This lemma is the smooth analogue of Exercise 14.6.

Lemma 33.5. (Smooth Homotopy Stacking Lemma) Let M be a smooth manifold and let $a < b < c$ be real numbers. Let $f\colon M \times [a,c] \to N$ be a map to some smooth manifold N. We suppose that the following statements hold:

(1) The restrictions of f to $M \times [a,b]$ and to $M \times [b,c]$ (both viewed as smooth manifolds with corner) are smooth.
(2) There exists an $\epsilon > 0$ such that for all $t \in [a,b]$ with $t \in (b-\epsilon, b+\epsilon)$ and all $x \in M$ we have $f(x,t) = f(x,b)$.



Then f itself is smooth.

Proof of the Smooth Homotopy Stacking Lemma 33.5. If $\partial M = \varnothing$, then the statement follows immediately from the Smooth Pasting Proposition 19.23. But as the meticulous reader will already have figured out, if $\partial M \neq \varnothing$, then there is one step which requires at least a little bit of thought. Namely, after taking charts for $P \in \partial M$ one sees that one still needs to prove the following claim.

Claim. Let V be an open subset of $\mathbb{H}^m$ and let $\varphi\colon V \times (b-\epsilon, b+\epsilon) \to \mathbb{R}^n$ be a map with the following properties:

(1) The restrictions of φ to $V \times (b-\epsilon, b] \to \mathbb{R}^n$ and $V \times [b, b+\epsilon) \to \mathbb{R}^n$ are smooth in the sense of the definition on page 532.
(2) For every $P \in V$ and $t \in [a,b]$ with $t \in (b-\epsilon, b+\epsilon)$ we have $\varphi(P,t) = \varphi(P,b)$.

Then φ is smooth in the sense of the definition on page 532.

Proof. As the reader can verify, this claim does *not* follow immediately from the definition. So let $P \in V$. By hypothesis there exists an open neighborhood U of $(P,b) \in \mathbb{R}^{m+1}$ and a smooth map $\widetilde{\varphi}\colon U \to \mathbb{R}^n$ with $\widetilde{\varphi} = \varphi$ on $U \cap (V \times (b-\epsilon, b])$. Now we consider the map

$$\begin{array}{rcl} \widetilde{\psi}\colon U & \to & \mathbb{R}^n \\ (P,t) & \mapsto & \widetilde{\varphi}(P,b). \end{array}$$

It follows easily from our hypothesis (2) that this map is smooth and that it agrees with φ on $U \cap (V \times (b-\epsilon, b+\epsilon))$. ∎

Proof of the Smooth Isotopy Transitivity Proposition 33.3.

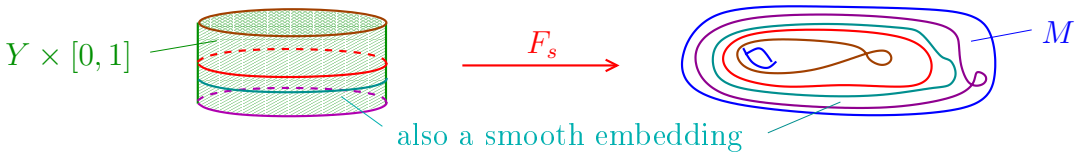
(1) The only non-trivial aspect is to show transitivity. We show how to prove this statement for "properly smoothly isotopic". All other cases are dealt with in the same way. Thus let $f, g, h\colon M \to N$ be proper smooth embeddings. We assume that f is properly smoothly isotopic to g and that g is properly smoothly isotopic to h. We need to show that f is properly smoothly isotopic to h.

Let $\Phi\colon M \times [0,1] \to N$ be a proper smooth isotopy from f to g. Furthermore let $\Psi\colon M \times [0,1] \to N$ be a proper smooth isotopy from g to h. After applying the Trivial-Near-The-Ends-Lemma 33.4 to Φ and Ψ we can arrange that there exists an $\epsilon \in (0,1)$ such that for each $P \in M$ and each $t \in [0,\epsilon]$ we have $\Phi(P, t-\epsilon) = g(P) = \Psi(P,\epsilon)$. Note that by the "furthermore" part of Trivial-Near-The-Ends-Lemma 33.4 we can

guarantee that along the way we did not lose the property of Φ and Ψ being proper smooth isotopies. Now we consider the map

$$\begin{array}{rcl} M \times [0,1] & \to & N \\ (P,t) & \mapsto & \begin{cases} \Phi(P, 2\cdot t), & \text{if } t \in [0, \frac{1}{2}], \\ \Psi(P, 2\cdot t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

By the Homotopy Stacking Lemma 33.5 we know that this map is smooth. It is now clear that this map is a proper smooth isotopy between f and h.



(2) If we are given a subset $A \subset M$ and if Φ and Ψ are smooth isotopies rel A, then it follows from the construction and Part (3) of the Trivial-Near-The-Ends-Lemma 33.4 that the above smooth isotopy is again rel A. ■

We conclude this section with a proposition that says, loosely speaking, that a smooth homotopy starting at a smooth embedding is for "small parameters" actually a smooth isotopy.

Proposition 33.6. (Deform Smooth Embedding Proposition) Let Y and M be smooth manifolds, let S be a smooth manifold without boundary and let $F\colon Y \times S \to M$ be a smooth map. We assume that Y is compact.

(1) Let $s \in S$ be a point such that the map $F_s\colon Y \to Y$ is a smooth embedding. There exists an open neighborhood U of s such that for every $t \in U$ the map $F_t\colon Y \to M$ is a smooth embedding.

(2) If in the setting of (1) the map F_s is actually a diffeomorphism and if Y and M are closed connected smooth manifolds, then there exists an open neighborhood U of s such that for every $t \in U$ the map $F_t\colon Y \to M$ is a diffeomorphism.

Proof.

(1) We consider the map

$$\begin{array}{rcl} \Phi\colon Y \times S & \to & M \times S \\ (y,t) & \mapsto & (F(y,t),t). \end{array}$$

Let $s \in S$ be a point such that the map $F_s\colon Y \to M$ is a smooth embedding. We observe that such $s \in S$ has the following two properties:

(a) The map $\Phi|_{Y\times\{s\}}\colon Y \times \{s\} \to M \times \{s\}$ is a smooth embedding.

(b) For each $y \in Y$ the differential $\mathrm{D}\Phi_{(y,s)}$ is a monomorphism. It follows from the Local Smooth Embedding Theorem 24.8 we obtain that for each $y \in Y$ the map Φ is locally a smooth embedding at (y,s).

We deduce from (a) and (b) together with the Neighborhood Smooth Embedding Theorem 10.13 that there exists an open neighborhood W of $Y \times \{s\} \subset Y \times S$ such that the restriction of Φ to $W \to M \times S$ is a smooth embedding. Since Y is compact we obtain from the elementary Exercise 5.9 that there exists an open neighborhood

U of $s \in S$ such that $Y \times U \subset W$. It follows that for each $t \in U$ the map

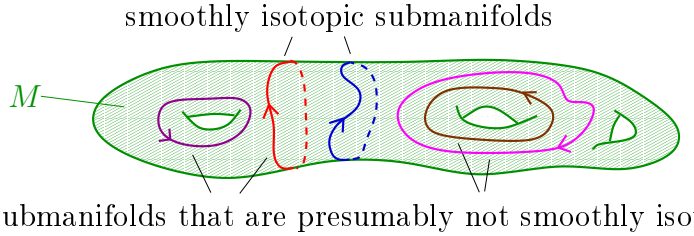
$$\begin{array}{rcl} \Phi_t \colon Y & \to & M \times \{t\} \subset M \times S \\ y & \mapsto & (F_t(y), y) \end{array}$$

is a smooth embedding. Finally note that this in turn implies immediately that for each $t \in U$ the map $F_t \colon Y \to M$ is also a smooth embedding.

(2) Now we assume that $F_s \colon Y \to M$ is a diffeomorphism and that Y and M are closed connected smooth manifolds. In particular we have $\dim(Y) = \dim(M)$. By (1) we know there exists an open neighborhood U of s such that for every $t \in U$ the map $F_t \colon Y \to M$ is a smooth embedding. Since Y is closed, since M is connected and since $\dim(Y) = \dim(M)$ we obtain from the Codimension-Zero Smooth Embedding Proposition 24.16 (3) that each F_t is actually a diffeomorphism. ■

33.2. **Smooth isotopies of (sub-) manifolds.** In this very short we introduce a few basic definitions which are slight variations on some of the definitions from the last section. The need for these variations will arise every now and then.

Definition. Let M_0, M_1 be two (proper) submanifolds of a smooth manifold N.



(1) A (proper) smooth isotopy between M_0 and M_1 is defined as a (proper) smooth isotopy $F \colon M_0 \times [0,1] \to N$ with $F_0 = \mathrm{id}_{M_0}$ and with $F_1(M_0) = M_1$.[339]

(2) We say that the two submanifolds M_0 and M_1 are (properly) smoothly isotopic if there exists a (proper) smooth isotopy between M_0 and M_1.

If M_0 and M_1 are oriented smooth manifolds, then we demand that the map $F_1 \colon M_0 \to M_1$ is orientation-preserving.

Remark. Let $F \colon M \times [0,1] \to N$ be a (proper) smooth isotopy. Recall that it follows from the Smooth Embedding Theorem 24.10 (1) that each $F_t(M)$ is a (proper) smooth submanifold of N. Thus, loosely speaking, two (proper) submanifolds are (properly) smoothly isotopic precisely if one submanifold can be smoothly deformed into the other through (proper) submanifolds.

Example. In the figure below we consider several oriented 1-dimensional submanifolds of a surface M. In some cases it is clear that submanifolds are smoothly isotopic, in other cases this looks dubious. In Chapter 43 we will get to know techniques which allow us to show that the dubious pairs of oriented 1-dimensional submanifolds are indeed not smoothly isotopic. In particular in Exercise 43.14 we will return to the given submanifolds.

For completeness' sake we state the following lemma which we will use implicitly on several occasions.

[339] Note that it follows from the Smooth Embedding Theorem 24.10 that $F_1 \colon M_0 \to M_1$ is a diffeomorphism.

Lemma 33.7. Let N be a smooth manifold. The property of being (properly) smoothly isotopic is an equivalence relation on the set of (proper) submanifolds of (oriented) submanifolds of M.

Proof. It follows almost immediately from the Smooth Isotopy Transitivity Proposition 33.3 that being (properly) smoothly isotopic is an equivalence relation. ■

33.3. **Examples of smooth homotopies.** In this section we will give several examples of smooth homotopies which will come in handy on numerous several occasions. We start out with an example of a diffeotopy.

Lemma 33.8. (Diffeotopies-via-Matrices Lemma) Let $n \in \mathbb{N}$.

(1) (a) If $\gamma\colon [0,1] \to \mathrm{GL}(n,\mathbb{R})$ is a smooth path[340], then the map

$$\begin{array}{rcl} F\colon \mathbb{R}^n \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & \gamma(t)\cdot x \end{array}$$

is a diffeotopy rel the origin.

(b) Given any $A \in \mathrm{GL}_+(n,\mathbb{R})$ there exists a diffeotopy of $\mathbb{R}^n$ from $\mathrm{id}_{\mathbb{R}^n}$ to the diffeomorphism of $\mathbb{R}^n$ that is given by multiplication by A.

(2) (a) If $\gamma\colon [0,1] \to \mathrm{O}(n)$ is a smooth path, then the map

$$\begin{array}{rcl} F\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \gamma(t)\cdot x \end{array}$$

is a diffeotopy rel the origin.

(b) Given any $A \in \mathrm{SO}(n)$ there exists a diffeotopy of $\overline{B}^n$ from $\mathrm{id}_{\overline{B}^n}$ to the diffeomorphism of $\overline{B}^n$ that is given by multiplication by A.

The same statements hold with $\overline{B}^n$ replaced by B^n and S^{n-1}.

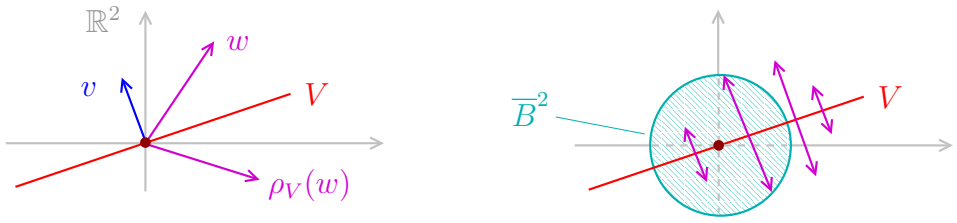
Proof. We first prove Statement (2) which is slightly more subtle.

(2) (a) By the Matrix Group-Smooth Manifold Proposition 26.7 we know that $\mathrm{O}(n)$ is a smooth submanifold of $\mathrm{M}(n\times n,\mathbb{R})$. By the Submanifold Smooth Structure Lemma 19.24 (1) the map γ, viewed as a map $\gamma\colon [0,1] \to \mathrm{M}(n\times n,\mathbb{R})$ is also smooth. It follows from this observation that the obvious extension of F to $\mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ is smooth. We deduce from Lemma 33.1, that the given map $F\colon \overline{B}^n \times [0,1] \to \overline{B}^n$ is also smooth. It is now clear that it is in fact a diffeotopy.

(b) Let $A \in \mathrm{SO}(n)$. By the Matrix Group Path-Component Proposition 2.37 we know that $\mathrm{SO}(n)$ is path-connected. It follows from this fact, together with the Smooth Path-Connectivity Proposition 19.29, that there exists a smooth map $\gamma\colon [0,1] \to \mathrm{SO}(n)$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. It follows from (2a) that there exists a diffeotopy of $\overline{B}^n$ from $\mathrm{id}_{\overline{B}^n}$ to the diffeomorphism of $\overline{B}^n$ that is given by multiplication by A.

[340] Let $G = \mathrm{GL}(n,\mathbb{R})$ or $G = \mathrm{O}(n)$. By the discussion on page 711 and by the Matrix Group-Smooth Manifold Proposition 26.7 we know that G is a smooth submanifold of $\mathrm{M}(n\times n,\mathbb{R})$. Thus by the Submanifold Smooth Structure Lemma 19.24 we can and will view G as a smooth manifold in its own right. In this sense we demand that the map $\gamma\colon [0,1] \to G$ is smooth. In practice though we use the Submanifold Smooth Structure Lemma 19.24 which says that if $\gamma\colon [0,1] \to \mathrm{M}(n\times n,\mathbb{R})$ is smooth in the ordinary sense, and if γ takes values in G, then $\gamma\colon [0,1] \to G$ is smooth.

By the same argument the analogous statements also hold for B^n and S^{n-1}.



(1) The proof of Statement (1) is almost verbatim the same as the proof of (2). Note that by the Matrix Group Path-Component Proposition 2.37 we know that $\mathrm{GL}_+(n,\mathbb{R})$ is path-connected. ■

To formulate our next example we recall the following definition which should be familiar from a course in linear algebra.

Definition. Let $n \in \mathbb{N}$ and let $V \subset \mathbb{R}^n$ be a hyperplane, i.e. V is a vector subspace of $\mathbb{R}^n$ codimension one. We pick a vector $v \in \mathbb{R}^n$ with $\|v\| = 1$ that is orthogonal to V. We refer to the map[341][342]

$$\begin{aligned} \rho_V \colon \mathbb{R}^n &\to \mathbb{R}^n \\ w &\mapsto w - 2 \cdot \langle v, w \rangle \cdot v \end{aligned}$$

as the reflection in the hyperplane V.

Lemma 33.9. Let $n \in \mathbb{N}$.

(1) Any reflection in a hyperplane of $\mathbb{R}^n$ has the following properties:
   (a) it is an orientation-reversing diffeomorphism,
   (b) it is an isometry (i.e. it preserves the Euclidean distance) and preserves the origin,
   (c) it restricts to orientation-reversing diffeomorphisms of $\overline{B}^n$ and S^{n-1}.

(2) Any two reflections in hyperplanes of $\mathbb{R}^n$ are in fact related by a diffeotopy $F \colon \mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ such that each F_t is also a reflection. In particular the diffeotopies are diffeotopies rel the origin. The diffeotopies restrict to diffeotopies of $\overline{B}^n$ and S^{n-1}.

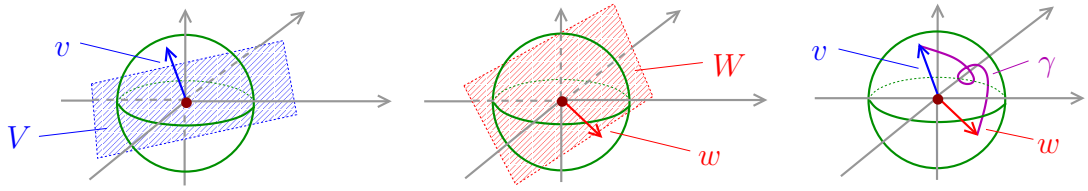
Proof. Let $n \in \mathbb{N}$.

(1) Let ρ be a reflection in a hyperplane of $\mathbb{R}^n$. Clearly ρ is smooth and it satisfies $\rho \circ \rho = \mathrm{id}_{\mathbb{R}^n}$. This implies immediately that ρ is a diffeomorphism. Next we want to show that $\rho \colon \mathbb{R}^n \to \mathbb{R}^n$ is orientation-reversing. By the Tangent Space-Isomorphism Proposition 23.16 and by the discussion on page 536 we have the following commutative diagram:

$$\begin{array}{ccc} \mathrm{T}_0\mathbb{R}^n & \xrightarrow[\cong]{\Theta_{\mathbb{R}^n}} & \widetilde{\mathrm{T}}_0\mathbb{R}^n = \mathbb{R}^n \\ {\scriptstyle \mathrm{D}\rho_0}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle \rho} \\ \mathrm{T}_0\mathbb{R}^n & \xrightarrow[\cong]{\Theta_{\mathbb{R}^n}} & \widetilde{\mathrm{T}}_0\mathbb{R}^n = \mathbb{R}^n. \end{array}$$

Elementary linear algebra shows that the right vertical map has negative determinant, which means that it is orientation-reversing. By Lemma 25.7 (2) this implies that the vertical map $\mathrm{D}\rho_0 \colon \mathrm{T}_0\mathbb{R}^n \to \mathrm{T}_0\mathbb{R}^n$ to the left is also orientation-reversing. It

[341] Note that v is well-defined up to sign, it follows easily that ρ_V does not depend on the choice of v.
[342] Here $\langle\ ,\ \rangle$ denotes the standard inner product on $\mathbb{R}^n$.



follows from the Basics-of-Orientations Lemma 25.13 that $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ is orientation-reversing.

A short amusing calculation shows that ρ preserves the scalar product, hence length. Since $\rho(0) = 0$ and since ρ preserves the Euclidean metric we see that ρ restricts to self-maps of $\overline{B}^n$ and S^{n-1}. It follows from the Submanifold Smooth Structure Lemma 19.24 that these self-maps are in fact diffeomorphisms of $\overline{B}^n$ and S^{n-1}. The same argument as above shows that the self-diffeomorphism of $\overline{B}^n$ is orientation-reversing. Finally it follows from the Boundary Orientation Lemma 25.17 (4) that the self-diffeomorphism of $S^{n-1} = \partial\overline{B}^n$ is also orientation-reversing

(2) Suppose we are given two hyperplanes V and W of $\mathbb{R}^n$. We pick vectors $v, w \in \mathbb{R}^n$ with $\|v\| = \|w\| = 1$ and with $v \perp V$ and $w \perp W$. By the Ball-Sphere-Connected Lemma 2.25 we know that S^{n-1} is path-connected. It follows from the Smooth Path-Connectivity Proposition 19.29 that there exists in fact a smooth path $\gamma\colon [0,1] \to S^{n-1}$ with $\gamma(0) = v$ and $\gamma(1) = w$. One can easily verify that the map

$$\begin{array}{rcl} F\colon \mathbb{R}^n \times [0,1] & \to & \mathbb{R}^n \\ (P,t) & \mapsto & P - 2\cdot\langle\gamma(t), P\rangle\cdot\gamma(t) \end{array}$$

is smooth. By construction $F_0 = \rho_V$ and $F_1 = \rho_W$. Thus F is the desired diffeotopy of $\mathbb{R}^n$. As in (1) we see that this diffeotopy of $\mathbb{R}^n$ restricts to a diffeotopy of $\overline{B}^n$ and to a diffeotopy of S^{n-1}. ■

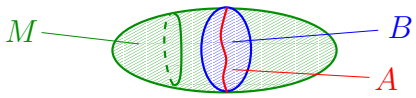
Given a topological space X and a subset A we defined on page 433 the notion of a deformation retraction $R\colon X \times [0,1] \to X$ from X to A. If X is a smooth manifold, then it makes sense to talk of a smooth deformation retraction. The following proposition, which is the smooth version of the Matrix Groups Deformation Retract Proposition 15.7, gives interesting examples of smooth deformation retractions.

Proposition 33.10. (Matrix Groups Smooth Deformation Retract Proposition) Let $n \in \mathbb{N}_0$ and let $k \in \{1, \ldots, n\}$. We write

$$\begin{array}{rcl} \mathrm{GL}(n,k) & = & \text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^n \\ \mathrm{O}(n,k) & = & \text{set of } k\text{-tuples of orthonormal vectors of } \mathbb{R}^n. \end{array}$$

(Note that for $k = n$ we have $\mathrm{GL}(n,k) = \mathrm{GL}(n)$ and $\mathrm{O}(n,k) = \mathrm{O}(n)$.) We denote by $r\colon \mathrm{GL}(n,k) \to \mathrm{O}(n,k)$ the map given by the Gram-Schmidt Orthonormalization Process 2.38. The above retraction $r\colon \mathrm{GL}(n,k) \to \mathrm{O}(n,k)$ is realized[343] by a smooth deformation retraction[344] $R\colon \mathrm{GL}(n,k)\times[0,1] \to \mathrm{O}(n,k)$ which has the following extra property:

($*$) For every k-dimensional vector subspace V of $\mathbb{R}^n$ and every $t \in [0,1]$ we have



$$R_t(\text{basis of } V) \;=\; \text{basis of } V.$$

The analogous statements hold if we replace the pair $\mathrm{O}(n,k)$ and $\mathrm{GL}(n,k)$ by one of the following four pairs:

(a)	$\mathrm{GL}_+(n,\mathbb{R})$	and	$\mathrm{SO}(n)$
(b)	$\mathrm{SL}(n,\mathbb{R})$	and	$\mathrm{SO}(n)$
(c)	$\mathrm{GL}(n,\mathbb{C})$	and	$\mathrm{U}(n)$
(d)	$\mathrm{SL}(n,\mathbb{C})$	and	$\mathrm{SO}(n)$.

Our proof of Proposition 33.10 rests on the following elementary lemma.

Auxiliary Lemma 33.11. Let M be a smooth manifold and let $A \subset B \subset X$ be a submanifolds. If A is a smooth deformation retract of B and if B is a smooth deformation retract of M, then A is a smooth deformation retract of X.

Proof of Lemma 33.11. The proof of the lemma follows from combining the ideas of the proof of the Iterated Deformation Retracts Lemma 15.4 and the proof of the Smooth Isotopy Transitivity Proposition 33.3. We leave it to the reader to fill in the details. ■

Sketch of a proof of Proposition 33.10. In the Matrix Groups Deformation Retract Proposition 15.7 we gave the same statement as above, except that we did not worry about smoothness. We will now see that demanding that the deformation retractions are smooth is not a big deal.

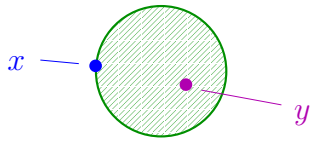
On page 173, in the proof of the Matrix Group Path-Component Proposition 2.37, we implicitly already showed that each of the $2k$ steps of the Gram-Schmidt Orthogonalization Process is realized by a smooth deformation retraction that satisfies $(*)$. It follows from Lemma 33.11 that these smooth deformation retractions give rise to the desired smooth deformation retraction

$$R\colon\ \mathrm{GL}(n,k)\times[0,1]\ \to\ \mathrm{GL}(n,k)$$

from $\mathrm{GL}(n,k)$ to $\mathrm{O}(n,k)$ such that R that satisfies $(*)$. If $n=k$, then it follows from the Gram-Schmidt Orthonormalization Process 2.38 (2) and (3) that this deformation retraction R restricts to a deformation retraction from $\mathrm{GL}_+(n,\mathbb{R})$ to $\mathrm{SO}(n)$ and from $\mathrm{SL}(n,\mathbb{R})$ to $\mathrm{SO}(n)$.

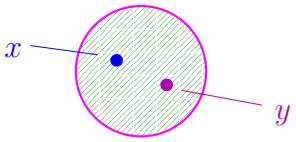
Finally note that the cases of the complex matrix groups are treated in a very similar fashion. ■

33.4. **Homogeneous topological spaces.** We start out with the following general definition.



Definition. Let X be a topological space.

(1) We say X is homogeneous if given any two points $x,y\in X$ there exists a homeomorphism $f\colon X\to X$ with $\varphi(x)=y$.



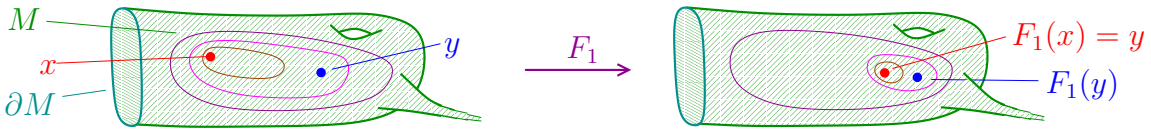
[343] Recall that by the definition on page 433 we say that a retraction $f\colon X\to A$ is realized by a deformation retraction $R\colon X\times[0,1]\to X$ if $R_1=f$.

[344] In Exercise 33.4 we will see that $\mathrm{GL}(n,k)$ is an open subset of $\mathbb{R}^{nk}$. Therefore the word "smooth" makes sense in the most naive sense.

(2) Let $A \subset X$ be a subset. We say X is homogeneous outside of A if given any two points $x, y \in X \setminus A$ there exists a homeomorphism $f\colon X \to X$ with $\varphi(x) = y$.

$\overline{B}^2$ is *not* homogenous

$\overline{B}^2$ is homogenous outside of S^1



Examples.

(1) It is clear that the topological space $\mathbb{R}^n$ is homogeneous. Furthermore, an easy linear algebra argument shows that the sphere S^n is homogeneous.
(2) Every set that is equipped with the trivial topology or the discrete topology is homogeneous.
(3) In Exercise 22.11 we showed that the long ling $\mathbb{L}$ is homogeneous.
(4) We consider the infinite product $X = \prod_{k\in\mathbb{N}} \{0,1\} = \{0,1\}^{\mathbb{N}}$ of the discrete space $\{0,1\}$. In Exercise 33.7 we will see that X is homogeneous. Note that on page 235 we saw that the Cantor set is homeomorphic to $\prod_{k\in\mathbb{N}} \{0,1\} = \{0,1\}^{\mathbb{N}}$. This gives us the not entirely intuitive conclusion, that the Cantor set is homogeneous.
(5) It follows basically immediately from the definitions that a topological manifold with non-empty boundary and non-empty interior is not homogeneous. In particular $[0,1]^m$ is not homogeneous. It is thus quite stunning that the Hilbert Cube[345], i.e. the topological space $\prod_{k\in\mathbb{N}} [0,1] = [0,1]^{\mathbb{N}}$, is actually homogeneous. A proof of this fact is given in [**Verb1969, HalW2012**].

For topological and smooth manifolds we are interested in finer notions of homogeneity, which leads us to the following definition.

Definition. Let M be a topological manifold and let $x, y \in M \setminus \partial M$. We say x can be moved to y if there exists a homeotopy $F\colon M \times [0,1] \to M$ with the following properties:
(1) $F_0 = \mathrm{id}$,
(2) $F_1(x) = y$,
(3) F is a homotopy rel some neighborhood of ∂M.
(4) F is a homotopy with compact support, i.e. there exists a compact subset $K \subset X$ such that $F(x,t) = x$ for all $x \notin K$ and all $t \in [0,1]$.

If M is a smooth manifold, then we demand that F is actually a diffeotopy.

The following proposition shows in particular that each compact interval $[a,b]$ is homogeneous outside of the set of endpoints $\{a,b\}$, that every sphere is homogeneous and that the closed ball $\overline{B}^n$ is homogeneous outside of the boundary sphere $\partial\overline{B}^n = S^{n-1}$.

[345] We encountered the Hilbert Cube in a slightly different avatar in Exercise 9.20.

Proposition 33.12.
(1) Let $a < b \in \mathbb{R}$. Given any $x, y \in (a, b)$ we can move x to y.
(2) Let $n \in \mathbb{N}$. Given any $x, y \in S^n$ we can move x to y.
(3) Let $n \in \mathbb{N}$. Given any $x, y \in \overline{B}^n \setminus \partial\overline{B}^n = B^n$ we can move x to y.

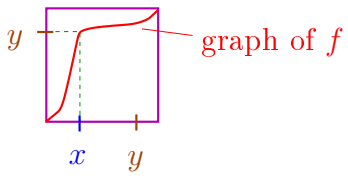
Remark.
(1) Note that Proposition 33.12 (3) gives in particular a solution to the rather challenging Exercise 19.21.
(2) In Proposition 35.14 we will use the Flow Theorem 35.1 to provide an alternative proof of Proposition 33.12 (3).

The proof of Proposition 33.12 rests on the following little lemma.

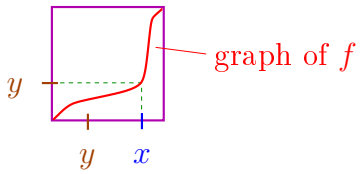
Auxiliary Lemma 33.13. Let M be a smooth manifold and let $x, y, z \in M \setminus \partial M$. If we can move x to y and if we can move y to z, then we can move x to z.

Proof of Lemma 33.13. Let $F\colon M \times [0,1] \to M$ and $G\colon M \times [0,1] \to M$ be diffeotopies as in the above definition such that $F_1(x) = y$ and such that $G_1(y) = z$. Using the Trivial-Near-The-Ends-Lemma 33.4 we can arrange that F and G are trivial near the ends. One can now verify easily that the map

$$\begin{array}{rcl} H\colon \times [0,1] & \to & M \\ (P,t) & \mapsto & \begin{cases} F(P, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ G(F_1(P), 2t-1), & \text{if } t \in [\frac{1}{2}, 1] \end{cases} \end{array}$$



has the desired properties. ∎



Proof of Proposition 33.12.

(1) Let $x, y \in (a, b)$. We leave it to the reader to show, say using the Smooth Transition Function Lemma 19.4, that there exists a diffeomorphism $f\colon [a,b] \to [a,b]$ with $f(x) = y$ and which is identity in a neighborhood of the two endpoints a and b. We consider the smooth homotopy

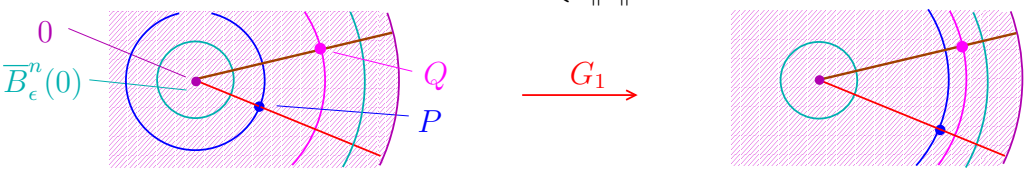
$$\begin{array}{rcl} F\colon [a,b] \times [0,1] & \to & [a,b] \\ (s,t) & \mapsto & s \cdot (1-t) + f(s) \cdot t \end{array}$$

which is evidently a homotopy rel an open neighborhood of $\{a, b\}$ with $F_0 = \mathrm{id}$ and $F_1 = f$. Since the derivative of f is strictly positive one sees easily, say using the Inverse Mapping Theorem 24.1 (2), that each F_t is a diffeomorphism of $[a, b]$, i.e. F is the promised diffeotopy.

(2) Let $n \in \mathbb{N}$ and let $x, y \in S^n$. By the Orthogonal Action Lemma 5.26 (4) we know that there exists an $A \in \mathrm{SO}(n+1)$ with $A \cdot x = y$. The desired orientation-preserving diffeomorphism is thus given by multiplication by A. By the Diffeotopies-via-Matrices Lemma 33.8 we know that this map is diffeotopic to the identity.

(3) The case $n = 1$ is a special case of (1). Thus let us now suppose that $n \geq 2$. Let $P, Q \in \overline{B}^n \setminus \partial\overline{B}^n = B^n$. First we deal with the case that $P, Q \neq 0$. We start out with the following claim.

Claim. There exists a diffeotopy $G\colon \overline{B}^n \times [0,1] \to \overline{B}^n$ with $G_0 = \mathrm{id}$, $G_1(\|P\|) = \|Q\|$ and such that G is a homotopy rel a neighborhood of the boundary.

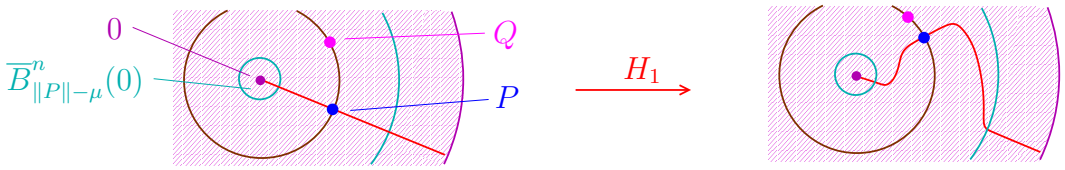


Proof. Since $P, Q \neq 0$ and since $P, Q \in B^n$ we see that $\|P\|, \|Q\| \in (0,1)$. Therefore it follows from (1) that there exists a diffeotopy $F\colon [0,1] \times [0,1] \to [0,1]$ with the following properties:

(a) We have $F_0 = \mathrm{id}$.
(b) The map $F_1\colon [0,1] \to [0,1]$ is a diffeomorphism with $F_1(\|P\|) = \|Q\|$.
(c) There exists an $\epsilon > 0$, such that $F(s,t) = s$ for all $s \in [0,\epsilon] \cup [1-\epsilon, 1]$ and all $t \in [0,1]$.

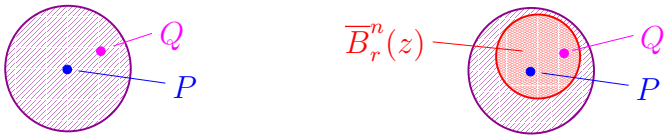
Using the Smooth Pasting Proposition 19.3 one can easily verify that the desired diffeotopy is given by

$$\begin{array}{rcl} G\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } \|x\| < \epsilon \\ \frac{x}{\|x\|} \cdot F(\|x\|, t), & \text{if } \|x\| > 0. \end{cases} \end{array}$$



⊞

It follows from the claim and Lemma 33.13 that it remains to deal with the case that $\|P\| = \|Q\|$. We pick $\mu > 0$ with $0 < \|P\| - \mu < \|P\| + \mu < 1$. We write $v := \frac{P}{\|P\|}$ and $w := \frac{Q}{\|Q\|}$. Since $n \geq 2$ it follows from (2) and the Trivial-Near-The-Ends-Lemma 33.4 that there exists a diffeotopy $F\colon S^{n-1} \times [0,\mu] \to S^{n-1}$ with $F_0 = \mathrm{id}$, with $F_\mu(v) = w$ and which is trivial near the ends. Again one can easily verify that the desired diffeotopy is given by the map



$$\begin{array}{rcl} H\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } \|x\| \in [0, \|P\| - \mu], \\ \|x\| \cdot F(\frac{x}{\|x\|}, t \cdot (\|x\| - \|P\| + \mu)), & \text{if } \|x\| \in [\|P\| - \mu, \|P\|], \\ \|x\| \cdot F(\frac{x}{\|x\|}, t \cdot (\|P\| + \mu - \|x\|)), & \text{if } \|x\| \in [\|P\|, \|P\| + \mu], \\ x, & \text{if } \|P\| \in [\|x\| + \mu, 1]. \end{cases} \end{array}$$

We have now settled the case that $P, Q \neq 0$.

Finally we need to deal with the case that one of two points $P, Q \in \overline{B}^n \setminus \partial\overline{B}^n = B^n$ is the origin. In this case we pick a closed ball $\overline{B}^n_r(z) \subset \overline{B}^n$ with $P, Q \in B^n_r(P)$ but with $z \neq P, Q$. We apply the above scheme to find a diffeotopy of $\overline{B}^n_r(z)$ that sends P to Q. Since the diffeotopy is a homotopy rel a neighborhood of the boundary

of $\overline{B}^n_r(z)$ we see that we can extend this diffeotopy via the constant homotopy to a diffeotopy of all of $\overline{B}^n$. This diffeotopy clearly has all the desired properties. ■

The following proposition implies in particular that connected topological manifolds without boundary are homogeneous.

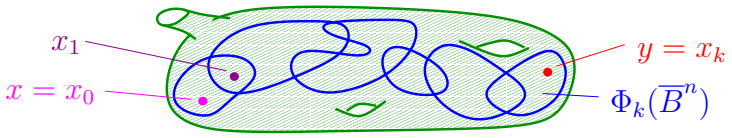
Proposition 33.14. (Homogeneous-via-Diffeotopies Proposition)

(1) Let M be a connected topological manifold. Given any $x, y \in M \setminus \partial M$ we can move x to y via a homeotopy.
(2) Let M be a connected smooth manifold. Given any $x, y \in M \setminus \partial M$ we can move x to y via a diffeotopy.

Remark. For smooth manifolds we will prove in Proposition 36.4 a refinement of the Homogeneous-via-Diffeotopies Proposition 33.14.

Proof. We prove the Homogeneous-via-Diffeotopies Proposition 33.14 for smooth manifolds. The case of topological manifolds follows by almost the same argument. Thus let M be a connected smooth manifold and let $x \in M \setminus \partial M$.

We say that $y \in M \setminus \partial M$ is *connected to x via balls* if there exist smooth embeddings $\Phi_i \colon \overline{B}^n \to M \setminus \partial M$, $i = 1, \ldots, k$ such that $x \in \Phi_1(B^n)$, $y \in \Phi_k(B^n)$ and such that for each $i = 1, \ldots, k-1$ we have $\Phi_i(B^n) \cap \Phi_{i+1}(B^n) \neq \varnothing$.



Claim. Every point in $M \setminus \partial M$ is connected to x via balls.

Proof. Recall that we assume that M is connected. It follows from the Topological Manifolds-Local Properties Lemma 18.8 and the Push Away From Boundary Lemma 18.13, see also Exercise 18.19, that $M \setminus \partial M$ is also connected. Now let U be the set of points in $M \setminus \partial M$ that are connected to x via balls.

- Since $x \in M \setminus \partial M$ we see that there exists a smooth embedding $\Phi \colon \overline{B}^n \to M \setminus \partial M$ with $x \in \Phi(B^n)$, thus $x \in U$, in particular U is non-empty.
- It is clear that U is open.
- Finally let $y \in \overline{U}$, where we take the closure of U in $M \setminus \partial M$. Again we see that there exists a smooth embedding $\Phi \colon \overline{B}^n \to M \setminus \partial M$ with $y \in \Phi(B^n)$. By the Codimension-Zero Smooth Embedding Proposition 24.16 we know that $\Phi(B^n)$ is an open neighborhood of y in $M \setminus \partial M$. Since $y \in \overline{U}$ we obtain from Lemma 1.10 (2) that there exists a point $\widetilde{y} \in \Phi(B^n) \cap U$. We can connect $\widetilde{y}$ to x via balls, but then we can also connect y to x via one extra ball. Thus we have shown that $y \in U$, i.e. we have shown that $U = \overline{U}$. By the Interior-Closure Lemma 1.9 (5) this implies that U is closed.

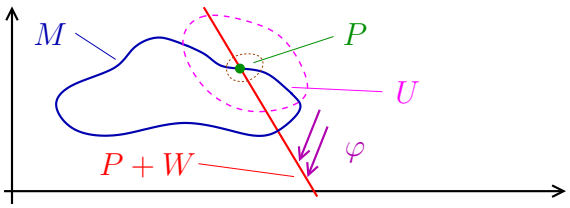
It follows from the above and the fact that $M \setminus \partial M$ is connected that $U = M \setminus \partial M$. ⊞

Now let $y \in M \setminus \partial M$. By the claim we know that y is connected to x via balls, i.e. there exist smooth embeddings $\Phi_i \colon \overline{B}^n \to M \setminus \partial M$, $i = 1, \ldots, k$ such that $x \in \Phi_1(B^n)$, $y \in \Phi_k(B^n)$ and such that for each $i = 1, \ldots, k-1$ there exists a point $x_i \in \Phi_i(B^n) \cap \Phi_{i+1}(B^n)$. We set $x_0 := x$ and $x_k := y$.

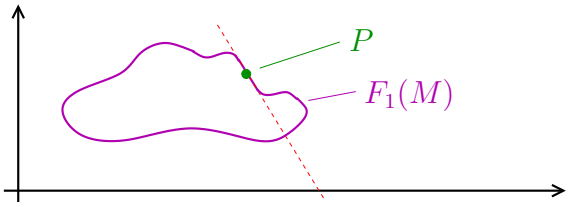
By Lemma 33.13 it remains to prove the following claim.

Claim 2. For each $i = 0, \dots, k-1$ we can move x_i to x_{i+1}.

Proof. Let $i \in \{0, \dots, k-1\}$. Note that by Proposition 33.12 (3) there exists an $r \in (0,1)$ and a diffeotopy $\Theta\colon \overline{B}^n \times [0,1] \to M$ rel $\{x \in \overline{B}^n \,|\, \|x\| \geq r\}$ with $\Theta_0 = \mathrm{id}$ and with $\Theta_1(\Phi_i^{-1}(x_i)) = \Phi_i^{-1}(x_{i+1})$. We set



$$\begin{array}{rcl} F_i\colon M \times [0,1] & \to & M \\ (x,t) & \mapsto & \begin{cases} \Phi_i(\Theta(\Phi_i^{-1}(x),t)), & \text{if } x \in \Phi_i(B^n), \\ x, & \text{otherwise} \end{cases} \end{array}$$



Note that F_i is well-defined and that it is smooth on the open subsets[346] $\Phi_i(B^n) \times [0,1]$ and $(M \setminus \Phi_i(\overline{B}^n_r)) \times [0,1]$ of $M \times [0,1]$. Thus F_i is smooth by the Smooth Pasting Proposition 19.23. One can now easily verify that F_i has the desired properties. ∎

33.5. **The Flattening Lemma.** We conclude this chapter with the following lemma, which is a little technical, but convenient at times.

Lemma 33.15. (Flattening Lemma) Let $M \subset \mathbb{R}^n$ be a smooth submanifold. Furthermore let $P \in M \setminus \partial M$, let $W \subset \mathbb{R}^n$ be a vector subspace and let $\varphi\colon \mathbb{R}^n \to W$ be a homomorphism such that $\varphi\colon \widetilde{\mathrm{T}}_P M \to W$ is a monomorphism. Given any open neighborhood U of $P \in M$ there exists a smooth isotopy $F\colon M \times [0,1] \to \mathbb{R}^n$ rel $(M \setminus U) \cup \{P\}$ and an open neighborhood $\widetilde{U}$ of $P \in M$ with the following properties:

(1) $F_0 = \mathrm{id}$,
(2) $\widetilde{\mathrm{T}}_P(F_1(M)) = \varphi(\widetilde{\mathrm{T}}_P M)$,
(3) $F_1(\widetilde{U}) \subset P + W$,
(4) for each $x \in M$ and each $t \in [0,1]$ the point $F(x,t)$ lies on the segment between x and $P + \varphi(x)$.

Proof. Let $M \subset \mathbb{R}^n$ be a k-dimensional smooth submanifold, let $P \in M \setminus \partial M$, let $W \subset \mathbb{R}^n$ be a vector subspace and let $\varphi\colon \mathbb{R}^n \to W$ be a homomorphism such that $\varphi\colon \widetilde{\mathrm{T}}_P M \to W$ is a monomorphism and let U be an open neighborhood of $P \in M$. We denote by $p\colon \mathbb{R}^n \to \mathbb{R}^k$

[346] It follows from the Codimension-Zero Smooth Embedding Proposition 24.16 that $\Phi_i(B^n) \times [0,1]$ is an open subset of $M \times [0,1]$. Furthermore it follows from the Compact Image Lemma 2.13, the Compact-Closed Lemma 1.21 and the fact that smooth manifolds are Hausdorff that $(M \setminus \Phi_i(\overline{B}^n_r)) \times [0,1]$ is also an open subset of $M \times [0,1]$.

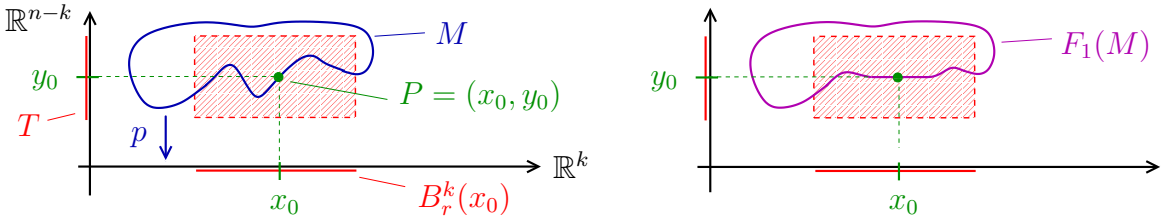
the projection onto the first k coordinates. It follows from elementary linear algebra, see Exercise 34.5, that there exists a linear isomorphism $\Phi\colon \mathbb{R}^n \to \mathbb{R}^n$ and a monomorphism $\chi\colon \mathbb{R}^k \to W$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{\mathrm{T}}_P M & \xrightarrow[\cong]{\Phi} & \Phi(\widetilde{\mathrm{T}}_P M) \\ \downarrow{\scriptstyle \varphi} & & {\scriptstyle p}\downarrow{\scriptstyle (x,y)\mapsto x} \\ W & \xleftarrow{\quad\chi\quad} & \mathbb{R}^k. \end{array}$$

Since $\mathrm{D}\Phi_P = \Phi$ we can assume, after replacing M by $\Phi(M)$, that $\varphi = \chi \circ p$.

We write $P = (x_0, y_0) \in \mathbb{R}^k \times \mathbb{R}^{n-k}$. It follows almost immediately from the Local Graph Lemma 24.4 that there exists an $r > 0$ and an open neighborhood T of $y_0 \in \mathbb{R}^{n-k}$ and a smooth map $f\colon B^k_r(x_0) \to T$ such that $B^k_r(x_0) \times T \subset U$ and such that

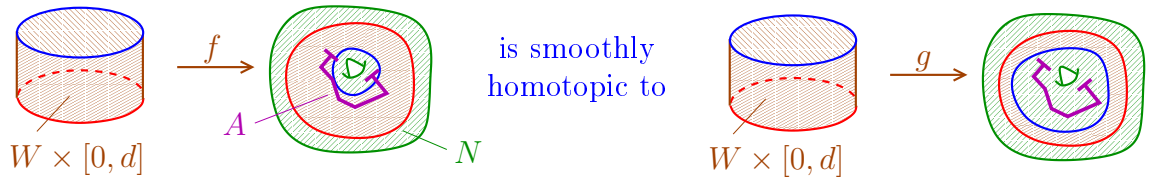
$$M \cap (B^k_r(x_0) \times T) = \text{ Graph of } f\colon B^k_r(x_0) \to T \;=\; \{(x, f(x)) \,|\, x \in B^k_r(x_0)\}.$$



Next note that by the Smooth Transition Function Lemma 19.4 there exists a smooth map $\gamma\colon B^k_r(x_0) \to [0,1]$ such that

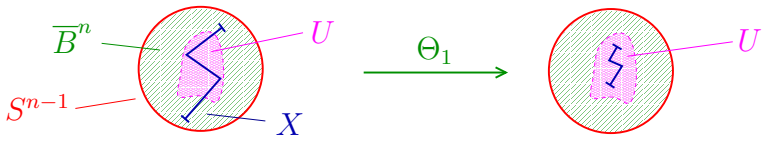
(a) if $\|x - x_0\| \geq \frac{r}{2}$, then $\gamma(x) = 0$,
(b) if $\|x - x_0\| \leq \frac{r}{4}$, then $\gamma(x) = 1$.

One can now easily verify that the map



$$\begin{array}{rcl} F\colon M \times [0,1] & \to & M \\ (Q,t) & \mapsto & \begin{cases} Q, & \text{if } Q \notin (B^k_r(x_0) \times T \\ (x, f(x) + (y_0 - f(x)) \cdot \gamma(x) \cdot t), & \text{if } Q = (x, f(x)) \text{ with } x \in B^k_r(x_0) \end{cases} \end{array}$$

has the desired properties. ∎



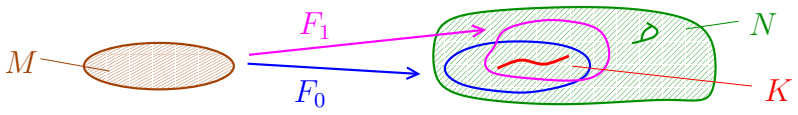
Exercises for Chapter 33.

Exercise 33.1. Let W be a compact smooth manifold without boundary and let N be a smooth manifold, possibly with boundary. Let $d > 0$ and let $f\colon W \times [0,d] \to N$ be a smooth embedding. Let A be a closed subset of M with $f(W \times \{0\}) \cap A = \varnothing$. Then the map f is smoothly isotopic rel $W \times \{0\}$ to a map $g\colon W \times [0,d] \to N$ with $g(W \times [0,d]) \cap A = \varnothing$.

Exercise 33.2. Let $n \in \mathbb{N}$, let $X \subset B^n$ be compact and let U be an open neighborhood of the origin $0 \in \overline{B}^n$. Show that there exists a diffeotopy $\Theta\colon \overline{B}^n \times [0,1] \to \overline{B}^n$ rel S^{n-1} such that $\Theta_0 = \mathrm{id}$ and such that $\Theta_1(X) \subset U$.

Exercise 33.3. Let M and N be two n-dimensional smooth manifolds. Furthermore let $F\colon M \times [0,1] \to N$ be a smooth isotopy.

(a) We suppose that there exists an open subset $V \subset N$ such that for each $t \in [0,1]$ we have $V \subset F_t(M \setminus \partial M)$. Show that the map



$$\begin{array}{rcl} \varphi\colon V \times [0,1] & \to & M \\ (P,t) & \mapsto & F_t^{-1}(P) \end{array}$$

is a smooth isotopy.
Hint. To show smoothness of φ you could use the Inverse Function Theorem 24.1 to show that the map $V \times [0,1] \to M \times [0,1]$ given by $(P,t) \mapsto (\varphi(P,t),t)$ is a local diffeomorphism.

(b) Let $K \subset N$ be a submanifold such that for each $t \in [0,1]$ we have $K \subset F_t(M \setminus \partial M)$. Show that the map

$$\begin{array}{rcl} K \times [0,1] & \to & M \\ (P,t) & \mapsto & F_t^{-1}(P) \end{array}$$

is a smooth isotopy.

Exercise 33.4. Let $n \in \mathbb{N}_0$ and let $k \in \{1,\dots,n\}$. We write

$$\mathrm{GL}(n,k) \;=\; \underbrace{\text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^n}_{\mathbb{R}^n \times \cdots \times \mathbb{R}^n = \mathbb{R}^{nk}}.$$

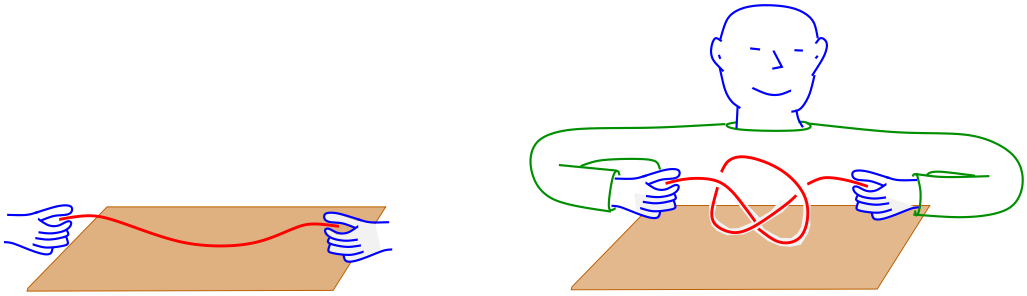
Show that $\mathrm{GL}(n,k)$ is an open subset of $\mathbb{R}^{nk}$.

Exercise 33.5. Let M be a connected smooth manifold.

(a) Let P, Q be points in $M \setminus \partial M$.
  (i) Show that if $\dim(M) \geq 2$, then there exists a diffeomorphism $f\colon M \to M$ that swaps P and Q and that is diffeotopic to the identity.
  (ii) For which 1-dimensional smooth manifolds does the conclusion of (i) hold?

(b) Let C be a component of ∂M and let P, Q be two points in C. Show that there exists a diffeomorphism $f\colon M \to M$ that swaps P and Q.
Hint. Use the Smooth Collar Neighborhood Theorem 28.3.

Exercise 33.6. Show that $\mathbb{R}/\mathbb{Q}$ is compact, that it is homogeneous and that it is not a topological manifold.



Exercise 33.7. Show that the topological space $\prod_{k\in\mathbb{N}} \{0,1\} = \{0,1\}^{\mathbb{N}}$ is homogeneous and show that it is not a topological manifold.
Remark. Note that by Tychonoff's Theorem 5.9 and the Product Topology Properties Proposition 5.8 we know that $\prod_{k\in\mathbb{N}} \{0,1\} = \{0,1\}^{\mathbb{N}}$ is compact and Hausdorff. Thus we see that there are compact Hausdorff spaces that are homogeneous but that are not topological manifolds.

Exercise 33.8.

(a) Let $n \geq 2$ and let M be a connected n-dimensional smooth manifold. Suppose we are given distinct points $P_1, \ldots, P_m$ and distinct points $Q_1, \ldots, Q_m$ in $M \setminus \partial M$. Show that there exists a diffeotopy with compact support, rel a neighborhood of ∂M, from the identity to a diffeomorphism $\Phi\colon M \to M$ with $\Phi(P_i) = Q_i$ for $i = 1, \ldots, m$.
Hint. Apply the Homogeneous-via-Diffeotopies Proposition 33.14 iteratively.
Remark. The same argument also works for topological manifolds where the conclusion is that we get an isotopy with compact support.

(b) Show that the conclusion of (a) is wrong for 1-dimensional smooth manifolds.

Exercise 33.9. Can you pick up a loose unknotted string with both hands and turn it into a knotted string as shown in the figure below, while holding on to the ends of the string? Either way, which smooth isotopy types of knotted strings can you produce this way?

Exercise 33.10. Let M and N be smooth manifolds and let $F\colon M \times \mathbb{R} \to N$ be a map such that each $F_t\colon M \to N$ is a (proper) smooth embedding. Show that

$$\begin{array}{rcl} M \times \mathbb{R} & \to & N \times \mathbb{R} \\ (P,t) & \mapsto & (F(P,t),t) \end{array}$$

is a (proper) smooth embedding.

34. Classification of certain diffeomorphisms up to diffeotopy

Given a smooth manifold one would like, ideally, to classify all diffeomorphisms up to diffeotopy and given two smooth manifolds one would like, ideally, to classify all smooth embeddings from one into the other up to smooth isotopy. Before we consider explicit examples let us introduce a few relevant definitions.

Definition. Let M and N be two smooth manifolds of the same dimension.

(1) We denote by $\mathrm{Diff}(M,N)$ the set of diffeomorphisms from M to N.
(2) By the Smooth Isotopy Transitivity Proposition 33.3 we know that "diffeotopy" defines an equivalence relation on $\mathrm{Diff}(M,N)$. We write

$$\widetilde{\mathrm{Diff}}(M,N) := \mathrm{Diff}(M,N)/\sim \qquad \text{where } f \sim g \text{ if } f \text{ and } g \text{ are diffeotopic.}$$

(3) If M and N are oriented, then it makes sense to restrict one selves to orientation-preserving diffeomorphisms and we obtain $\mathrm{Diff}^+(M,N)$ and $\widetilde{\mathrm{Diff}}^+(M,N)$.

Furthermore, given a single smooth manifold M we write $\mathrm{Diff}(M) := \mathrm{Diff}(M,N)$ and accordingly for all the related notions.

Remark. If M is a smooth manifold, then $\mathrm{Diff}(M)$ is evidently a group. Furthermore it is not difficult to see that this group structure descends to a group structure on $\widetilde{\mathrm{Diff}}(M)$. This group is also called the mapping class group $\mathrm{MCG}(M)$. We will study it in greater detail in Section **??**.

Definition. Let M and N be two smooth manifolds.

(1) We denote by $\mathrm{Emb}(M,N)$ the set of smooth embeddings $M \to N$.
(2) By the Smooth Isotopy Transitivity Proposition 33.3 we know that "smooth isotopy" defines an equivalence relation on $\mathrm{Emb}(M,N)$. We write

$$\widetilde{\mathrm{Emb}}(M,N) := \mathrm{Emb}(M,N)/\sim \qquad \text{where } f \sim g \text{ if } f \text{ and } g \text{ are smoothly isotopic.}$$

(3) If M and N are oriented and of the same dimension, then it makes sense to restrict one selves to orientation-preserving smooth embeddings and we obtain $\mathrm{Emb}^+(M,N)$ and $\widetilde{\mathrm{Emb}}^+(M,N)$.

For completeness' sake we state the following rather obvious lemma.

Lemma 34.1. Let M and N be two smooth manifolds and let $\varphi\colon A \to M$ and $\psi\colon N \to B$ be diffeomorphisms between smooth manifolds.

(1) The maps

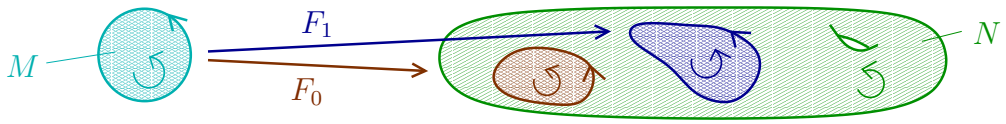
$$\begin{array}{rcl} \mathrm{Diff}(M,N) & \to & \mathrm{Diff}(A,B) \\ f & \mapsto & \psi \circ f \circ \varphi \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \widetilde{\mathrm{Diff}}(M,N) & \to & \widetilde{\mathrm{Diff}}(A,B) \\ [f] & \mapsto & [\psi \circ f \circ \varphi] \end{array}$$

are bijections. If all smooth manifolds are oriented and if φ and ψ are orientation-preserving, then the obvious analogues for Diff^+ and $\widetilde{\mathrm{Diff}}^+$ also hold.
(2) The analogues for Emb instead of Diff also hold.

Proof. The lemma follows immediately from Lemma 33.2. ∎

Given two smooth manifolds M and N it is in general surely too difficult to describe $\mathrm{Diff}(M,N)$ and $\mathrm{Emb}(M,N)$ in a meaningful way. It is more realistic to try to get a handle on $\widetilde{\mathrm{Diff}}(M,N)$ and $\widetilde{\mathrm{Emb}}(M,N)$. But even this problem becomes very hard very quickly.

Example. In the figure below we see two smooth embeddings $f,g\colon S^1\to\mathbb{R}^3$. It is perhaps intuitively clear that the two smooth embeddings are not smoothly isotopic, i.e. that they represent different points in $\widetilde{\mathrm{Emb}}(S^1,\mathbb{R}^3)$. But a proper proof will have to wait till Proposition 59.6.



The example shows that if at this stage we want to give a classification we will need to restrict ourselves to fairly basic situations. In fact in this chapter we will consider the following:

(1) diffeomorphisms of $\mathbb{R}^n$,
(2) smooth embeddings $\overline{B}^n\to\mathbb{R}^n$,
(3) smooth embedding $\overline{B}^k\to\mathbb{R}^n$ for $k<n$,
(4) diffeomorphisms of S^1.

34.1. **Diffeotopies and orientations.** We start out with the following proposition, which might be intuitively obvious, but which is somewhat subtle to prove.

Proposition 34.2. (Smooth Isotopy-Orientation Proposition) Let M and N be oriented connected smooth manifolds of the same dimension and let $F\colon M\times[0,1]\to N$ be a smooth isotopy.[347] Then either all smooth embeddings $F_t\colon M\to N$ are orientation-preserving or all F_t are orientation-reversing.

Proof. Let M and N be oriented connected n-dimensional smooth manifolds and let $F\colon M\times[0,1]\to N$ be a smooth isotopy. We consider the sets

$$\begin{aligned} A &:= \{(x,t)\in M\times[0,1]\,|\,\mathrm{D}(F_t)_x\colon \mathrm{T}_xM\to\mathrm{T}_{F_t(x)}N \text{ is orientation-preserving}\}\\ B &:= \{(x,t)\in M\times[0,1]\,|\,\mathrm{D}(F_t)_x\colon \mathrm{T}_xM\to\mathrm{T}_{F_t(x)}N \text{ is orientation-reversing}\}. \end{aligned}$$

We need to show that $A=M\times[0,1]$ or $B=M\times[0,1]$. Since M is connected we know, by the Product Topology Properties Proposition 5.6 (3), that $M\times[0,1]$ is also connected. Thus it suffices to prove the following claim.

Claim. The subsets A and B are both open subsets of $M\times[0,1]$.

Proof. We will show that A is open. The proof that B is open is basically the same. Now let $(x,t)\in A$. We pick an orientation-preserving chart[348] $\Psi\colon V\to\widetilde{V}$ for $F_t(x)\in N$.

[347] The case of a diffeotopy is of course an important special case.

[348] Here we equip the open subset $\widetilde{V}$ of $\mathbb{R}^n$ with the standard orientation.

Since $F\colon M \times [0,1] \to N$ is in particular continuous we know that $F^{-1}(V)$ is open. Since $(x,t) \in F^{-1}(V)$ there exists an open subset of the form $U \times I$ of $M \times [0,1]$ such that $(x,t) \in U \times I \subset F^{-1}(V)$. After possibly making U even smaller we can assume that there exists an orientation-preserving chart $\Phi\colon U \to \widetilde{U}$ for M.

Claim. The map[349]

$$\begin{array}{rcl} \theta\colon U \times I & \to & \mathbb{R} \setminus \{0\} \\ (y,s) & \mapsto & \det \big(\underbrace{\mathrm{D}(\Psi \circ F_s \circ \Phi^{-1})_{\Phi(y)}}_{n \times n\text{-matrix}} \big) \end{array}$$

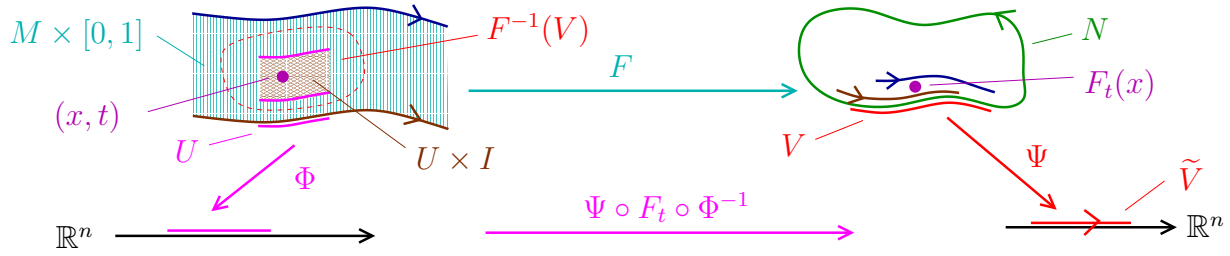
has the following two properties:

(1) For $(y,s) \in U \times I$ we have $(y,s) \in A$ if and only if $\theta(y,s) > 0$.
(2) The map θ is continuous.

Proof.

(1) Let $(y,s) \in U \times I$. By the Tangent Space-Functor Proposition 23.10 we have

$$\mathrm{D}(\Psi \circ F_s \circ \Phi^{-1})_{\Phi(y)} = \mathrm{D}\Psi_{F_s(y)} \circ \mathrm{D}(F_s)_y \circ \mathrm{D}(\Phi^{-1})_{\Phi(y)}.$$



Since the charts Ψ and Φ are by our choice orientation-preserving we know that $\mathrm{D}\Psi_{F_s(y)}\colon \mathrm{T}_{F_s(y)}M \to \mathrm{T}_{\Psi(F_s(y))}\widetilde{V}$ and $\mathrm{D}(\Phi^{-1})_{\Phi(y)}\colon \mathrm{T}_{\Phi(y)}\widetilde{U} \to \mathrm{T}_y V$ are orientation-preserving. It follows from the elementary the Orientation-Composition Lemma 25.3 that the composition is orientation-preserving if and only if $\mathrm{D}(F_s)_y$ is orientation-preserving. But that is what we needed to show.

(2) Note that for each $\widetilde{y} \in \widetilde{U}$ and each $s \in I$ we have

$$(\Psi \circ F_s \circ \Phi^{-1})(\widetilde{y}) \;=\; (\Psi \circ F \circ \underbrace{(\Phi^{-1} \times \mathrm{id}_I)}_{\text{map } \widetilde{U} \times I \to U \times I})(\widetilde{y}, s).$$

Since $\Psi \circ F \circ (\Phi^{-1} \times \mathrm{id}_{[0,1]})$ is a smooth map from $\widetilde{U} \times I \subset \mathbb{R}^n \times \mathbb{R}$ to $\mathbb{R}^n$ we see that the determinant of the differential is a continuous map on $\widetilde{U} \times I$. But this implies that θ is indeed continuous. ⊞

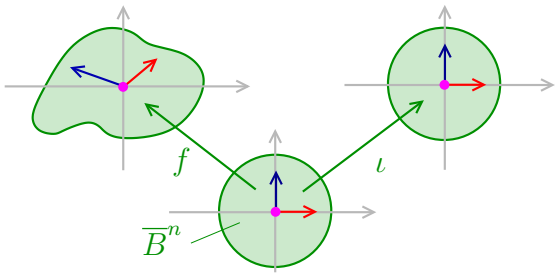
Since $(x,t) \in A$ we obtain from the claim that $\theta(x,t) > 0$. By the claim we also know that θ is continuous. Since $U \times I$ is connected we see that θ is positive on all of $U \times I$. But again by the claim this means that $U \times I \subset A$. It follows from the JH-Lemma 1.7 that A is indeed open. ■

[349] As usual we use the Differential-equals-Differential Lemma 23.4 and the Tangent Space-Isomorphism Proposition 23.16 to freely go back and forth between the different notions of differentials.

34.2. Diffeotopies of $\mathbb{R}^n$ and smooth embeddings of balls into $\mathbb{R}^n$.

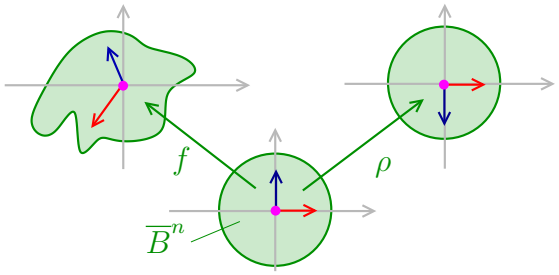
Proposition 34.3. (Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition) Let $n \in \mathbb{N}_0$.

(1) Let $f\colon \mathbb{R}^n \to \mathbb{R}^n$ be a diffeomorphism.
   (a) If f is orientation-preserving, then f is diffeotopic to the identity map.
   (b) If f is orientation-reversing, then f is diffeotopic to the reflection $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ that is given by $(x_1, x_2, \dots, x_n) \mapsto (-x_1, x_2, \dots, x_n)$.



(2) Let $f\colon \overline{B}^n \to \mathbb{R}^n$ be a smooth embedding.
   (a) If f is orientation-preserving, then f is smoothly isotopic to the inclusion ι.
   (b) If f is orientation-reversing, then f is smoothly isotopic to the reflection $\rho|_{\overline{B}^n}$.
   The same conclusion also holds for smooth embeddings $f\colon \overline{B}^n \to B^n_r(0)$ into a smooth ball of radius $r > 1$.

(3) Let $k < n$. Every smooth embedding $f\colon \overline{B}^k \to \mathbb{R}^n$ is smoothly isotopic to the "standard" smooth embedding given by



$$\begin{array}{rcl} \iota\colon \overline{B}^k & \to & \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k} \\ x & \mapsto & (x, 0). \end{array}$$

   The same conclusion also holds for smooth embeddings $f\colon \overline{B}^k \to B^n_r(0)$ into a smooth ball of radius $r > 1$.

In any of the above cases we have the following refinement: if $f(0) = 0$, then we can find a diffeotopy rel $\{0\}$ respectively a smooth isotopy rel $\{0\}$.

f orientation-preserving

f orientation-reversing

Remark. In the Smooth Ball Embedding Theorem 37.8 and in the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 we will classify smooth embeddings of closed balls into smooth manifolds. This result can be viewed as a generalization of the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2).

Proof. We start out with a few preparations:

- In the following we use on several occasions the fact, proved in the Smooth Isotopy Transitivity Proposition 33.3, that being diffeotopic and being smoothly isotopic is an equivalence relation.
- Given a matrix $A \in \mathrm{M}(m \times n, \mathbb{R})$ we denote by $\mu(A)\colon \mathbb{R}^n \to \mathbb{R}^m$ the map that is given by multiplication by A.
- We use the Differential-equals-Differential Lemma 23.4 as an excuse not to distinguish in our notation between the differential as a matrix and as a map.

Now we turn to the actual proof.

(1) First let $f\colon \mathbb{R}^n \to \mathbb{R}^n$ be an orientation-preserving diffeomorphism. Evidently there is a diffeotopy to a map that sends the origin to the origin. So by the Smooth Isotopy Transitivity Proposition 33.3 we might as well assume that $f(0) = 0$. We write $A := \mathrm{D}f_0$.

Claim. The map f is diffeotopic to the map $\mu(A)$.

Proof. Since $\mathbb{R}^n$ is a convex subset of $\mathbb{R}^n$ that contains the origin and since $f(0) = 0$ we know by the Map-as-Matrix Multiplication Proposition 19.14 that there exists a smooth map $\Theta\colon \mathbb{R}^n \to \mathrm{M}(n \times n, \mathbb{R})$ such that $\Theta(0) = A = \mathrm{D}f_0$ and such that for all $x \in \mathbb{R}^n$ we have $f(x) = \Theta(x) \cdot x$. We consider the map

$$\begin{array}{rcl} F\colon \mathbb{R}^n \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & \underbrace{\Theta(t \cdot x)}_{\in \mathrm{M}(n\times n,\mathbb{R})} \cdot x. \end{array}$$

This map is evidently smooth. Furthermore note that we have $F_1 = f$ and note that $F_0 = \mu(A) = \mu(\mathrm{D}f_0)$. It remains to show that each F_t is a diffeomorphism. This is clear for $t = 0$. For $t \neq 0$ we see that

$$F_t(x) \;=\; \Theta(t \cdot x) \cdot x \;=\; \tfrac{1}{t} \cdot \Theta(t \cdot x) \cdot (t \cdot x) \;=\; \tfrac{1}{t} \cdot f(t \cdot x).$$

Thus we see that F_t is the composition of the three diffeomorphisms $x \mapsto t \cdot x$, $y \mapsto f(y)$ and $z \mapsto \frac{1}{t} z$. Hence F_t is a diffeomorphism itself. ⊞

Next note that our hypothesis that the diffeomorphism f is orientation-preserving implies by the Basics-of-Orientations Lemma 25.13 that $\det(A) > 0$, in other words, $A \in \mathrm{GL}_+(n, \mathbb{R})$. By the Diffeotopies-via-Matrices Lemma 33.8 we know that multiplication by A is diffeotopic to the identity. Thus we are done by the Smooth Isotopy Transitivity Proposition 33.3.

Now we consider the case that f is orientation-reversing. There are two approaches to dealing with this situation. We can run exactly the same argument as above, except that we now use that $\det(\mathrm{D}f_0) < 0$ and that therefore $\mathrm{D}f_0$ lies in the same path-component of $\mathrm{GL}(n, \mathbb{R})$ as the orthogonal matrix representing the reflection ρ.

Alternatively we can note that $\rho \circ f$ is orientation-preserving. We can apply the above result to $\rho \circ f$ and we obtain a diffeotopy $F\colon \mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ with $F_0 = \rho \circ f$ and $F_1 = \mathrm{id}$. Since $\rho \circ \rho = \mathrm{id}$ we see that $\rho \circ F$ is now the desired diffeotopy from f to ρ.

(2) Let $f\colon \overline{B}^n \to \mathbb{R}^n$ be a smooth embedding. It follows by basically exactly the same argument as in (1) that the smooth embedding is either smoothly isotopic to the standard inclusion or to the reflection. We leave the few remaining details to the reader.

Now assume that we are given an $r > 1$ and an orientation-preserving smooth embedding $f\colon \overline{B}^n \to B^n_r(0)$. As we saw in Exercise 19.1, using the Smooth Transition Function Lemma 19.4 one can easily find a diffeomorphism $\varphi\colon [0, r) \to [0, \infty)$ which is the identity on $[0, 1]$. This diffeomorphism φ gives rise to the orientation-preserving

diffeomorphism

$$\begin{array}{rcl}\Phi\colon B_r^n(0) & \to & \mathbb{R}^n \\ v & \mapsto & \varphi(\|v\|)\cdot v\end{array}$$

which is the identity on $\overline{B}^n$. By the above discussion there exists a smooth isotopy $H\colon \overline{B}^n \times [0,1] \to \mathbb{R}^n$ with $H_0 = \Phi \circ f$ and such that H_1 is the inclusion. The desired smooth isotopy is now given by $(x,t) \mapsto \Phi^{-1}(H(x,t))$. The case that f is orientation-reversing is handled in the same way.

(3) Let $k < n$ and let $f\colon \overline{B}^k \to \mathbb{R}^n$ be a smooth embedding. As in (1) we might as well assume that $f(0) = 0$. Throughout the following discussion we make use of the following two projections:

$$\begin{array}{rcl}p\colon \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k} & \to & \mathbb{R}^k \\ (x,y) & \mapsto & x\end{array} \quad \text{and} \quad \begin{array}{rcl}q\colon \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k} & \to & \mathbb{R}^{n-k} \\ (x,y) & \mapsto & y.\end{array}$$

Claim 1. The smooth embedding $f\colon \overline{B}^k \to \mathbb{R}^n$ is smoothly isotopic to a smooth embedding $g\colon \overline{B}^k \to \mathbb{R}^n$ such that $\mathrm{D}(p\circ g)_0\colon \mathrm{T}_0\,\overline{B}^k \to \mathbb{R}^k$ is an isomorphism.

Proof. Since f is a smooth embedding we know that the matrix $\mathrm{D}f_0 \in \mathrm{M}(n\times k)$ has rank k. It follows from $k \leq n$ and some elementary linear algebra that there exists a matrix $A \in \mathrm{GL}_+(n,\mathbb{R})$ such that the first k rows of $A \cdot \mathrm{D}f_P$ have rank k. This is equivalent to the statement that

$$p \circ \underbrace{\mathrm{D}(\mu(A)\circ f)_0}_{\text{represented by } A\cdot \mathrm{D}f_0} = \mathrm{D}(p\circ\mu(A)\circ f)_0\colon\ \mathrm{T}_0\,\overline{B}^k \ \to\ \mathbb{R}^k$$

is an isomorphism. By the Matrix Group Path-Component Proposition 2.37 we know that $\mathrm{GL}_+(n)$ is path-connected. It follows from this fact, together with the Smooth Path-Connectivity Proposition 19.29, that there exists a smooth map $\gamma\colon [0,1] \to \mathrm{GL}_+(n)$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. Similar to the Diffeotopies-via-Matrices Lemma 33.8 (1a) we know consider the smooth isotopy

$$\begin{array}{rcl}F\colon \overline{B}^k \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & \gamma(t)\cdot f(x).\end{array}$$

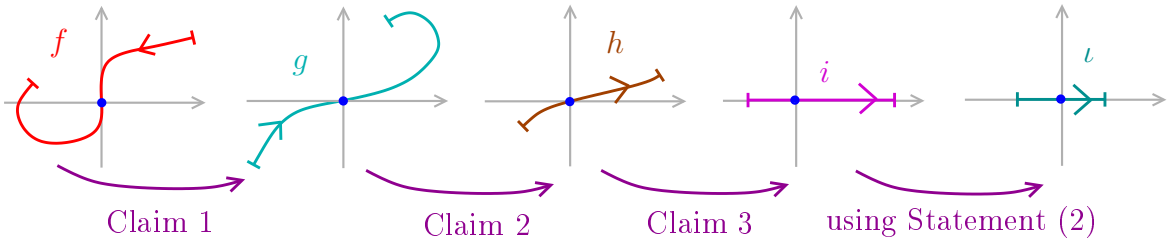
⊞

Claim 2. The smooth embedding $g\colon \overline{B}^k \to \mathbb{R}^n$ is smoothly isotopic to a smooth embedding $h\colon \overline{B}^k \to \mathbb{R}^n$ such that $p\circ h\colon \overline{B}^k \to \mathbb{R}^k$ is a smooth embedding.

Proof. Recall that the map $\mathrm{D}(p\circ g)_0\colon \mathrm{T}_0\,\overline{B}^k \to \mathbb{R}^k$ is an isomorphism. It follows almost immediately from the Inverse Mapping Theorem 24.1 that there exists an $r > 0$ such that $p\circ g\colon \overline{B}^k_r(0) \to \mathbb{R}^k$ is a smooth embedding. The desired smooth isotopy is now given by

$$\begin{array}{rcl}G\colon \overline{B}^k \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & g(x\cdot(1-t+t\cdot r)).\end{array}$$

⊞



Claim 3. The smooth embedding $h\colon \overline{B}^k \to \mathbb{R}^n$ is smoothly isotopic to a smooth embedding $i\colon \overline{B}^k \to \mathbb{R}^n$ that takes values in $\mathbb{R}^k \times \{0\}$.

Proof. We consider the map

$$\begin{array}{rcl} H\colon \overline{B}^k \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & ((p\circ h)(x), (1-t)\cdot(q\circ h)(x)). \end{array}$$

Since $p\circ h\colon \overline{B}^k \to \mathbb{R}^k$ is a smooth embedding we see that each $H_t\colon \overline{B}^k \to \mathbb{R}^n$ is a smooth embedding. In particular H is a smooth isotopy. Note that $H_0 = h$. Finally note that H_1 takes values in $\mathbb{R}^k \times \{0\}$. ⊞

Note that it follows from (2) that there exists a smooth isotopy $I\colon \overline{B}^k \times [0,1] \to \mathbb{R}^k$ from $p\circ i$ to $\mathrm{id}_{\overline{B}^k}$. Finally note that this smooth isotopy I evidently gives rise to a smooth isotopy $\overline{B}^k \times [0,1] \to \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k}$ from i to the standard smooth embedding $\iota\colon \overline{B}^k \to \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k}$ that is given by $x \mapsto (x,0)$.

Now assume that we are given an $r > 1$ and an orientation-preserving smooth embedding $f\colon \overline{B}^k \to B^n_r(0)$. As in (2) we can reduce this case to the case of a smooth embedding $\overline{B}^k \to \mathbb{R}^n$, so we are done by the above discussion. ■

The following is our first classification result of this chapter.

Corollary 34.4. Given $n \in \mathbb{N}$ and given $k \in \{1,\dots,n\}$ we consider the maps

$$\begin{array}{rcl} \rho\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ (x_1,\dots,x_n) & \mapsto & (-x_1,x_2,\dots,x_n) \end{array} \quad \text{and} \quad \begin{array}{rcl} \iota_k\colon \overline{B}^k & \to & \mathbb{R}^n \\ x & \mapsto & (x,0) \end{array}$$

With this notation the following statements hold:

(1) For $n \in \mathbb{N}$ we have $\widetilde{\mathrm{Diff}}^+(\mathbb{R}^n) = \{[\mathrm{id}]\}$ and $\widetilde{\mathrm{Diff}}(\mathbb{R}^n) = \{[\mathrm{id}],[\rho]\}$.

(2) For $n \in \mathbb{N}$ we have $\widetilde{\mathrm{Emb}}^+(\overline{B}^n,\mathbb{R}^n) = \{[\iota_n]\}$ and $\widetilde{\mathrm{Diff}}(\overline{B}^n,\mathbb{R}^n) = \{[\iota_n],[\rho|_{\overline{B}^n}]\}$.

(3) For $k < n$ we have $\widetilde{\mathrm{Emb}}(\overline{B}^k,\mathbb{R}^n) = \{[\iota_k]\}$.

Proof. The three statements follow immediately from the combination of Propositions 34.2 and 34.3. ■

34.3. **Smooth homotopies and diffeotopies of S^1.** In the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 we obtained a very good understanding of diffeotopies of $\mathbb{R}^n$. In this section we will use the statement for $n = 1$ to classify the diffeomorphisms of S^1 up to diffeotopy. More precisely we will prove the following proposition.

Proposition 34.5. (Diffeotopies-of-S^1-Classification Proposition) Let $f\colon S^1 \to S^1$ be a diffeomorphism.

(1) If f is orientation-preserving, then f is diffeotopic to the identity.

(2) If f is orientation-reversing, then f is diffeotopic to the reflection $\rho\colon S^1 \to S^1$ that is given by $(x,y) \mapsto (x,-y)$.

Remark.

(1) In Lemma 50.1 we proved an analogous statement for self-homeomorphisms of S^1.
(2) In Exercise 35.5 we will use the Flow Theorem 35.13 to give an alternative proof of the Diffeotopies-of-S^1-Classification Proposition 34.5.
(3) The Smale Theorem 146.7 and the Cerf Theorem 58.5 say that the obvious analogues of the Diffeotopies-of-S^1-Classification Proposition 34.5 hold for S^2 and S^3. But in Proposition **??** and Theorem **??** we will see that in general the naive analogues in higher dimensions do *not* hold. More precisely, there exist infinitely many $n \in \mathbb{N}_{\geq 6}$ such that the sphere S^n admits an orientation-preserving self-diffeomorphism that is not diffeotopic to the identity.

Before we turn to the proof of the Diffeotopies-of-S^1-Classification Proposition 34.5 let us first state and prove the following almost immediate useful corollary.

Corollary 34.6. (Diffeomorphisms-of-S^1-Extension Corollary) Every diffeomorphism $f\colon S^1 \to S^1$ extends to a diffeomorphism of $\overline{B}^2$.

Remark.

(1) In Exercise 5.35 we encountered the Alexander trick, which shows that every homeomorphism of S^n extends to a homeomorphism of $\overline{B}^{n+1}$.
(2) In contrast to the setting of homeomorphisms the analogue of the Diffeomorphisms-of-S^1-Extension Corollary 34.6 does *not* hold in all dimensions. More precisely, in Proposition **??** we will see that there exists a diffeomorphism $f\colon S^6 \to S^6$ that does not extend to a diffeomorphism of $\overline{B}^7$.

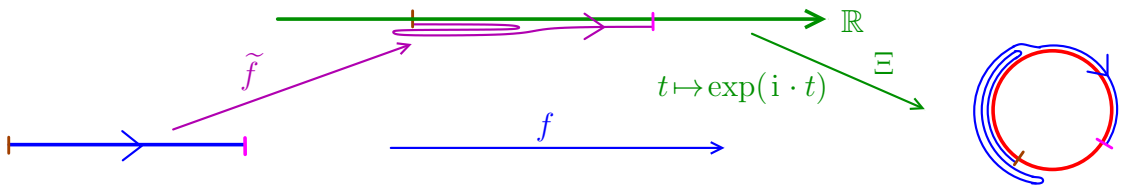
Proof of Corollary 34.6 assuming Proposition 34.5. Let $f\colon S^1 \to S^1$ be a diffeomorphism. By (1) we know that there exists a diffeotopy $F\colon S^1 \times [0,1] \to S^1$ from $F_0 = f$ to the identity $F_1 = \mathrm{id}$ or to the reflection $F_1 = \rho$. By the Trivial-Near-The-Ends-Lemma 33.4 we can arrange that F is trivial near the ends. In particular we can assume that there exists an $\epsilon > 0$ such that $F_t = F_1$ for all $t \in [1-\epsilon, 1]$. We consider the following map:

$$\begin{array}{rcl} \Phi\colon \overline{B}^2 & \to & \overline{B}^2 \\ P = (x,y) & \mapsto & \begin{cases} P = (x,y), & \text{if } \|P\| \leq \frac{1}{2} \text{ and if } f \text{ is orientation-preserving,} \\ (x,-y), & \text{if } \|P\| \leq \frac{1}{2} \text{ and if } f \text{ is orientation-reversing,} \\ \|P\| \cdot F\big(\frac{P}{\|P\|}, 2 - 2\cdot\|P\|\big), & \text{if } \|P\| \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

It follows easily from the Smooth Pasting Proposition 19.23 that the above map $\Phi\colon \overline{B}^2 \to \overline{B}^2$ is indeed smooth. Furthermore in Exercise 34.6 we will write down an explicit inverse to Φ and we will show that the inverse is smooth. This implies that Φ is indeed a diffeomorphism. ■

The proof of the Diffeotopies-of-S^1-Classification Proposition 34.5 requires some preparations, which are IMHO actually interesting in their own right. First we introduce the following notation:

Notation. Throughout this section we work with the map



$$\begin{array}{rcl} \Xi\colon \mathbb{R} & \to & S^1 \\ t & \mapsto & \exp(\mathrm{i}\cdot t). \end{array}$$

Lemma 34.7. Let $t \in \mathbb{R}$. The restriction of Ξ to $(t-\pi, t+\pi) \to S^1 \setminus \{-\Xi(t)\}$ is a diffeomorphism.

Proof. The lemma can be proved easily using the Smooth Embedding Theorem 24.10. Alternatively, as we saw in Exercise 19.6, it is not difficult to prove the lemma with one's bare hands. ■

Definition. Let $I \subset \mathbb{R}$ be an interval and let $f\colon I \to S^1$ be a map. A lift of f is a map[350] $\widetilde{f}\colon I \to \mathbb{R}$ such that $\Xi \circ \widetilde{f} = f$, in other words, such for all $t \in I$ we have

$$f(t) \;=\; \exp\big(\mathrm{i}\cdot \widetilde{f}(t)\big).$$

Remark. On pages 1078 and 1080 we will greatly generalize the notion of a lift.

Lemma 34.8. Let $I \subset \mathbb{R}$ be an interval and let $f\colon I \to S^1$ be a map. If f is smooth, then every lift is also smooth.

Proof. This statement follows from the Smooth Pasting Proposition 19.23 (3) together with the fact, implicitly shown in Lemma 34.7, that $\Xi\colon \mathbb{R} \to S^1$ is a local diffeomorphism. ■

In the proof of the Diffeotopies-of-S^1-Classification Proposition 34.5 we will also make use of the following very interesting lemma.

Lemma 34.9. (Lifting from S^1-to-$\mathbb{R}$ Lemma) Let $I \subset \mathbb{R}$ be an interval and let $x_0 \in I$. Given any map $f\colon I \to S^1$ and given any $\widetilde{y}_0 \in \mathbb{R}$ with $f(x_0) = \exp(\mathrm{i}\cdot \widetilde{y}_0)$ there exists a *unique* lift $\widetilde{f}\colon I \to \mathbb{R}$ of f with $\widetilde{f}(x_0) = \widetilde{y}_0$.

Remark. The Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 is an immediate consequence of the general theory of coverings that we will study in great detail in Chapter 48. More precisely, it follows from the discussion on page 1074 and the Actions-Covering Proposition 48.9 that the map $\Xi\colon \mathbb{R} \to S^1$ is a covering. The statement of the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 follows now from a slight variation on Proposition 48.11. Since at this stage we do not assume that the reader is familiar with covering theory we will now give a self-contained proof of the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9.

Proof. Our first claim already deals with the uniqueness statement of the proposition.

[350] Evidently this map is required to be continuous.

Claim 1. Let J be an interval, let $f\colon J \to S^1$ be a map and let $\widetilde{\varphi}, \widetilde{\psi}\colon J \to \mathbb{R}$ be two lifts of f. If $\widetilde{\varphi}$ and $\widetilde{\psi}$ agree at some point $t_0 \in J$, then they agree everywhere.

Proof. We consider the map

$$\begin{array}{rccc} \theta\colon & J & \to & \mathbb{R} \\ & s & \mapsto & \widetilde{\varphi}(s) - \widetilde{\psi}(s). \end{array}$$

By hypothesis we have $\theta(t_0) = 0$. Furthermore note that for each $t \in J$ we have

$$\underbrace{\exp\big(\mathrm{i}\cdot(\widetilde{\varphi}(s) - \widetilde{\psi}(s))\big)}_{=\exp(\mathrm{i}\cdot\theta(t))} = \exp\big(\mathrm{i}\cdot\widetilde{\varphi}(s)\big)\cdot\exp\big(\mathrm{i}\cdot\widetilde{\psi}(s)\big)^{-1} \underset{\substack{\uparrow \\ \text{since } \widetilde{\varphi},\widetilde{\psi}\colon J\to\mathbb{R} \text{ are lifts of } f}}{=} f(s)\cdot f(s)^{-1} = 1.$$

It follows that for every $s \in J$ we have $\exp(2\pi\,\mathrm{i}\cdot(\widetilde{\varphi}(s) - \widetilde{\psi}(s))) = 1$. This shows that the map $s \mapsto \mu(s) := \widetilde{\varphi}(s) - \widetilde{\psi}(s)$ takes values in $\mathbb{Z}$. Since J is connected it follows from the Connected-to-Discrete Lemma 2.27 that the map μ is constant. Since the map μ vanishes at t_0 we see that it is zero everywhere. ⊞

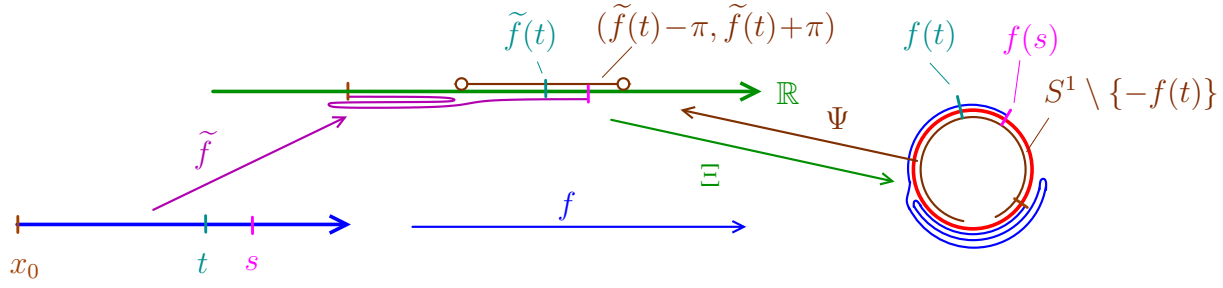
Claim 2. Let $b \in \mathbb{R}$ and let $s \in \mathbb{R} \cup \{\infty\}$ with $s > b$. If for every $c \in [b, s)$ there exists a lift of $f|_{[b,c]}$, then there exists also a lift of $f_{[b,s)}$.

Proof. It follows from the previous claim that the lifts on the various intervals agree on the overlaps. Thus they define a lift on all of $[b, s)$. ⊞

To simplify the notation we now only deal with the case that the interval is given by $I = [x_0, \infty)$. The proof of the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 for all other types of intervals is done in a very similar fashion. We set

$$S := \{s \in [x_0, \infty) \,|\, \text{there exists a lift of } \varphi|_{[x_0,s]}\}.$$

By Claim 2 it suffices to prove the following claim.



Claim 3. $S = [x_0, \infty)$.

Proof. Note that $x_0 \in S$. Since $[x_0, \infty)$ is connected if suffices to show that S is open and closed in $[x_0, \infty)$. It follows from elementary arguments, see the Interior-Closure Lemma 1.9 (5), that it suffices to show that for every $s \in [x_0, \infty)$ with $[x_0, s) \subset S$ there exists an $\epsilon > 0$, such that $[x_0, s + \epsilon) \subset S$.

Thus suppose we are given an $s \in [x_0, \infty)$ with $[x_0, s) \subset S$. By Claim 2 there exists a lift $\widetilde{f}\colon [x_0, s) \to \mathbb{R}$. We pick $t \in [x_0, s)$ such that $f([t, s]) \subset S^1 \setminus \{-f(s)\}$. Recall that by Lemma 34.7 we know that $\Xi\colon (\widetilde{f}(t) - \pi, \widetilde{f}(t) + \pi) \to S^1 \setminus \{-f(t)\}$ is a diffeomorphism. We denote its inverse by Ψ. Since f is continuous and since $f(s) \in S^1 \setminus \{-f(t)\}$ there exists an $\epsilon > 0$ such that $f([s, s + \epsilon)) \subset S^1 \setminus \{-f(t)\}$. Finally we consider the map

$$\begin{array}{rccc} & [x_0, s+\epsilon) & \to & \mathbb{R} \\ & x & \mapsto & \begin{cases} \widetilde{f}(x), & \text{if } x \le s, \\ \Psi(f(x)), & \text{if } x \in [s, s+\epsilon). \end{cases} \end{array}$$

Note that $\widetilde{f}$ and $\Psi \circ f$ are lifts of f on $[s, t]$ and note that they agree on t. Thus it follows from Claim 1 that they also agree on s. This shows that this map is in fact well-defined at s. It now follows from the Pasting Proposition 2.6 that this map is continuous. It is clear that it is a lift of $\varphi|_{[x_0,s+\epsilon)}$. Thus we see that $[x_0, s + \epsilon) \subset S$. ■

Now we can finally provide the long awaited proof of the Diffeotopies-of-S^1-Classification Proposition 34.5.

Proof of the Diffeotopies-of-S^1-Classification Proposition 34.5. Let $f\colon S^1 \to S^1$ be a diffeomorphism. First we consider the case that f is orientation-preserving. Note that by the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9, applied to the map $f \circ \Xi\colon \mathbb{R} \to S^1$, there exists a map $\widetilde{f}\colon \mathbb{R} \to \mathbb{R}$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathbb{R} & \xrightarrow{\widetilde{f}} & \mathbb{R} \\ {\scriptstyle t\mapsto \exp(it)}\big\downarrow{\scriptstyle \Xi} & & {\scriptstyle \Xi}\big\downarrow{\scriptstyle t\mapsto \exp(it)} \\ S^1 & \xrightarrow{f} & S^1. \end{array}$$

We make the following observations regarding $\widetilde{f}$:

(a) As we observed in Lemma 34.8, it follows from the fact that Ξ is a local diffeomorphism, together with the hypothesis that f is a smooth map, that $\widetilde{f}$ is also smooth.

(b) Recall that on page 682 we showed that Ξ is an orientation-preserving local diffeomorphism. Since f is orientation-preserving we see that $\widetilde{f}$ is also orientation-preserving. As we saw in the elementary Exercise 25.18, the above implies that $\widetilde{f}$ is a strictly monotonously increasing function.

(c) Since f is a diffeomorphism and since the above diagram commutes we see that for any $x \in \mathbb{R}$ the restriction of $\widetilde{f}$ to the interval $[x, x+2\pi)$ defines a bijection with $[f(x), f(x)+2\pi)$.

(d) Given $x \in \mathbb{R}$ it follows immediately from the commutativity of the above diagram, that the equality $\widetilde{f}(x+2\pi) - \widetilde{f}(x) \in \mathbb{Z} \cdot 2\pi$ holds.

(e) It follows from (b), (c) and (d) that for any $x \in \mathbb{R}$ we have $\widetilde{f}(x+2\pi) = \widetilde{f}(x) + 2\pi$.

Now we consider the map

$$\begin{array}{rcl} \widetilde{F}\colon \mathbb{R} \times [0,1] & \to & \mathbb{R} \\ (x,t) & \mapsto & \widetilde{f}(x)\cdot(1-t) + x \cdot t. \end{array}$$

This map is evidently smooth. Since the map $x \mapsto x$ has the above Properties (a) to (e) one can see easily that for any $t \in [0,1]$ the map $\widetilde{F}_t\colon \mathbb{R} \to \mathbb{R}$ has the above Properties (a) to (e). This implies in particular that the map $\widetilde{F}$ descends to a map

$$\begin{array}{rcl} F\colon S^1 \times [0,1] & \to & S^1 \\ (\Xi(x),t) & \mapsto & \Xi(\widetilde{f}(x)\cdot(1-t) + x \cdot t) \end{array}$$

where each $F_t\colon S^1 \to S^1$ is a homeomorphism. Since each $\widetilde{F}_t$ is a local diffeomorphism and since Ξ is a local diffeomorphism we obtain from the Smooth Pasting Proposition 19.23 (2) that each F_t is in fact a diffeomorphism. We have thus shown that F is indeed a diffeotopy from f to the identity.

Finally we consider the case that f is orientation-reversing. In this case $\rho \circ f$ is orientation-preserving. We apply the above result to $\rho \circ f$ and we obtain a diffeotopy $F\colon S^1 \times [0,1] \to S^1$ with $F_0 = \rho \circ f$ and $F_1 = \mathrm{id}$. Since $\rho \circ \rho = \mathrm{id}$ we see that $\rho \circ F$ is now the desired diffeotopy from f to ρ. ■

The following is our second classification result of this chapter.

Corollary 34.10. Let $\rho\colon S^1 \to S^1$ be the reflection that is given by $(x, y) \mapsto (x, -y)$. With this notation the following statements hold:

$$\widetilde{\mathrm{Diff}}^+(S^1) = \{[\mathrm{id}]\} \qquad \text{and} \qquad \widetilde{\mathrm{Diff}}(S^1) = \{[\mathrm{id}], [\rho]\}.$$

Proof. The statements follow immediately from the combination of Propositions 34.2 and 34.5. ■

Remark. In Exercise 34.1 we will pick up the last piece of low hanging fruit, namely we will determine $\widetilde{\mathrm{Diff}}^+(\overline{B}^1)$ and $\widetilde{\mathrm{Diff}}(\overline{B}^1)$.

Exercises for Chapter 34.

Exercise 34.1. Show that every diffeomorphism of $[-1, 1] = \overline{B}^1$ that preserves the boundary is diffeotopic to the identity.

Exercise 34.2. Let $I \subset \mathbb{R}$ be an interval and let $x_0 \in I$. Let $f, g\colon I \to S^1$ be two maps with $f(x_0) = g(x_0)$ and let $\widetilde{f}, \widetilde{g}\colon I \to \mathbb{R}$ be two lifts with $\widetilde{f}(x_0) = \widetilde{g}(x_0)$. Show that if $f, g\colon I \to S^1$ are homotopic rel $\{x_0\}$, then $\widetilde{f}$ and $\widetilde{g}$ are homotopic rel $\{x_0\}$.

Exercise 34.3. We consider the map

$$\begin{array}{rcl} \exp\colon \mathbb{C} & \to & \mathbb{C} \setminus \{0\} \\ z & \mapsto & \exp(z). \end{array}$$

Show that given any map $f\colon [a, b] \to \mathbb{C} \setminus \{0\}$ and given any $w \in \mathbb{C}$ with $\exp(z) = w$ there exists a unique map $\widetilde{f}\colon [a, b] \to \mathbb{C} \setminus \{0\}$ with $\widetilde{f}(a) = w$ and such that $\exp \circ \widetilde{f} = f$, i.e. such that for all $t \in [a, b]$ we have $\exp(\widetilde{f}(t)) = f(t)$.

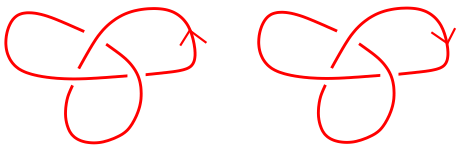
Exercise 34.4.

(a) Show that every diffeomorphism of the half-open interval $[0, 1)$ is every orientation-preserving.

(b) Show that every diffeomorphism of the half-open interval $[0, 1)$ is diffeotopic to the identity.

Exercise 34.5. Let $T \subset \mathbb{R}^n$ be a k-dimensional vector subspace, let $W \subset \mathbb{R}^n$ be a vector space and let $\varphi\colon \mathbb{R}^n \to W$ be a homomorphism such that $\varphi\colon T \to W$ is a monomorphism. We denote by $p\colon \mathbb{R}^n \to \mathbb{R}^k$ the projection onto the first k coordinates. Show that there

exists a linear isomorphism $\Phi\colon \mathbb{R}^n \to \mathbb{R}^n$ and a monomorphism $\chi\colon \mathbb{R}^k \to W$ such that $\varphi = \chi \circ p \circ \Phi$, i.e. such that the following diagram commutes:



$$\begin{array}{ccc} T & \xrightarrow[\cong]{\Phi} & \Phi(T) \\ \downarrow{\scriptstyle \varphi} & & {\scriptstyle p}\downarrow{\scriptstyle (x,y)\mapsto x} \\ W & \xleftarrow{\chi} & \mathbb{R}^k. \end{array}$$

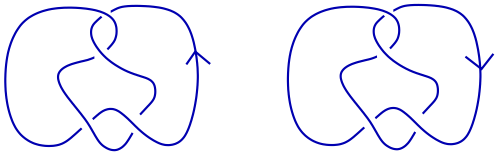
Exercise 34.6. Let $f\colon S^1 \to S^1$ be a diffeomorphism and let $F\colon S^1 \times [0,1] \to S^1$ be a diffeotopy with $F_0 = f$ and $F_1 = \mathrm{id}$. Furthermore let $\varphi\colon [\frac{1}{2}, 1] \to [0,1]$ be a smooth map with $\varphi(t) = 0$ for $t \in [\frac{1}{2}, \frac{5}{8}]$ and with $\varphi(t) = 1$ for $t \in [\frac{7}{8}, 1]$. We consider the following map:

$$\begin{array}{rcl} \Phi\colon \overline{B}^2 & \to & \overline{B}^2 \\ P = (x,y) & \mapsto & \begin{cases} P = (x,y), & \text{if } \|P\| \le \frac{1}{2}, \\ \|P\| \cdot F\big(\frac{P}{\|P\|}, f(2 - 2\cdot\|P\|)\big), & \text{if } \|P\| \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

Write down an explicit inverse of Φ and show that the inverse is smooth.

Exercise 34.7. For the purpose of this exercise an *oriented knot* is an oriented submanifold of $\mathbb{R}^3$ that is diffeomorphic to S^1. An oriented knot K is called *reversible* if there exists a smooth isotopy $F\colon K \times [0,1] \to \mathbb{R}^3$ such that $F_0\colon K \to \mathbb{R}^3$ is the inclusion and such that $F_1\colon K \to \mathbb{R}^3$ restricts to an orientation-reversing diffeomorphism $F_1\colon K \to K$. Show that the trefoil and the figure-8 knot are reversible. In other words, show that the two oriented knots shown in the figure to the left, respectively to the right, are smoothly isotopic.

trefoil with the two orientations



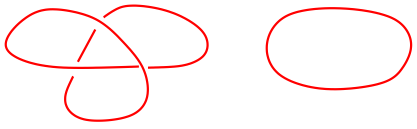


figure-8 knot with the two orientations

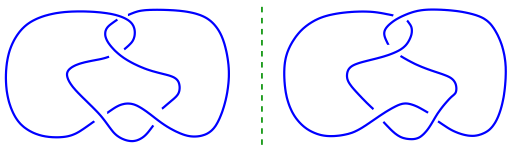


Exercise 34.8. For the purpose of this exercise a *knot* is a submanifold of $\mathbb{R}^3$ that is diffeomorphic to S^1. We say that two knots K and J are *smoothly isotopic* if there exists a smooth isotopy $F\colon S^1 \times [0,1] \to \mathbb{R}^3$ such that $F_0(S^1) = K$ and $F_1(S^1) = J$. We define the *mirror image* K^{mir} of a knot K to be the reflection of K in a hyperplane of $\mathbb{R}^3$.

(a) Show that any two mirror images of a given knot are smoothly isotopic.
(b) We say a knot is *amphichiral* if it is smoothly isotopic to its mirror image. Show that the figure-8 knot is amphichiral.

Remark. In Proposition 131.5 and also in Proposition 149.10 we will see that the trefoil is not amphichiral.

smoothly isotopic knots

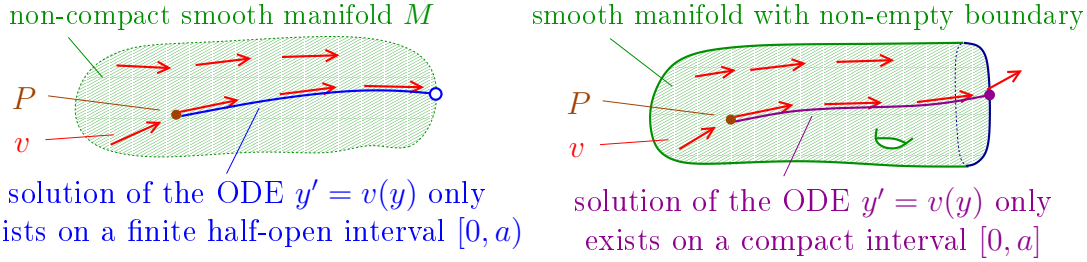
the figure-8 knot K and its mirror K^{mir}

Exercise 34.9. What is the cardinality of the set $\mathrm{Emb}(\{1,\dots,n\}, S^1)$?

35. The Flow Theorem

On page 639 we introduced the notion of a smooth vector field on a smooth manifold. In this section we state the Flow Theorem that shows in particular that smooth vector fields give rise to diffeotopies. The Flow Theorem cuts both ways. It will help us to construct interesting diffeotopies using smooth vector fields, this occurs for example in the proof of the Isotopy Extension Theorem 36.1. But later on, using information on diffeotopies, it will also help us to prove results on what type of smooth vector fields can occur on a smooth manifold. One such instance is given in the proof of the Smooth Poincaré-Hopf Theorem 45.17 and much later in the proof of the Euler Characteristic-Vector Field Theorem 97.15.

35.1. Statement of the Flow Theorem.



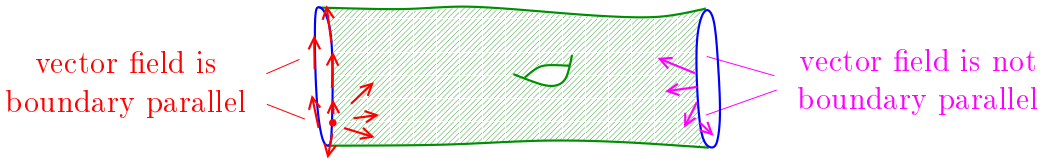
Definition. Let M be a smooth manifold and let v be a smooth vector field on M, as defined on page 638.

(1) Let I be an interval with non-empty interior. We say a smooth map $\varphi\colon I \to M$ is a[351] solution of the ODE $y' = v(y)$ if for every $t \in I$ we have the following equality:[352]

$$\varphi'(t) \;=\; v(\varphi(t)) \;\in\; \mathrm{T}_{\varphi(t)}M.$$

(2) A complete v-flow is a smooth map $F\colon M \times \mathbb{R} \to M$ that satisfies the following properties:
   (a) For each $P \in M$ we have $F(P, 0) = P$.
   (b) For each $P \in M$ the map $\mathbb{R} \to M$ given by $t \mapsto F(P, t)$ is a solution of the ODE $y' = v(y)$.

The reader might remember from an earlier course the Fundamental Theorem 35.7 for Autonomous ODEs which says, under mild hypotheses, that "short term" solutions of ODEs exist and that they are unique in a suitable sense. But note, as we can see in the figure below, these solutions might not be defined on all of $\mathbb{R}$. In particular there are hazards if the smooth manifold is non-compact and also if the smooth manifold has non-empty boundary.



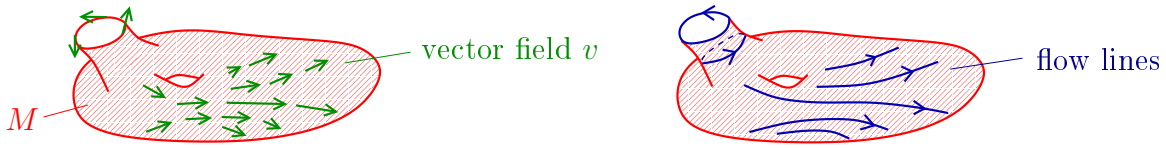
We will get around these issues by considering only compact smooth manifolds and by restricting ourselves to the following type of vector fields.

[351] Here ODE is short for "ordinary differential equation". Note that we do not define the notion of an ODE, we just define the expression "solution of an ODE $y' = v(y)$".

[352] We refer to page 637 for the definition of $\varphi'(t)$. As discussed on page 533, the fact that the interior of the interval is non-empty implies that we can talk sensibly of φ' at the endpoints of the interval.

Definition. Let M be a smooth manifold and let v be a vector field on M. We say v is boundary parallel if for each $P \in \partial M$ we have[353] $v(P) \in \mathrm{T}_P \partial M$.

Now we are in a position to state the main theorem of this chapter.



Theorem 35.1. (Flow Theorem) Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. There exists a unique complete v-flow $\Phi^v \colon M \times \mathbb{R} \to M$.

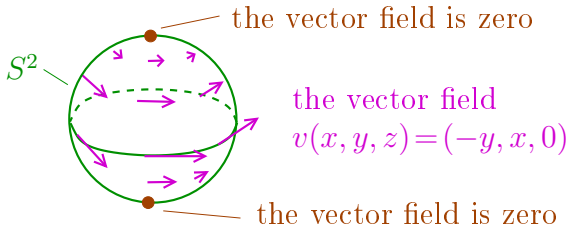
Remark. Statements that are very similar to our Flow Theorem 35.1 can also be found in [**Lee2002**, Theorem 9.12], [**Wall2016**, Theorem 1.4.2] and [**BJ1982**, Theorem 8.10].

The proof of the Flow Theorem 35.1 will consist of massaging the Fundamental Theorem for Autonomous ODEs 35.7, which, to most readers who made it that far, will be familiar from an earlier real analysis class. The proof of the Flow Theorem 35.1 is somewhat lengthy, thus we postpone the proof to the next section. In the following we prefer to discuss the Flow Theorem 35.1 and to consider an interesting addendum.

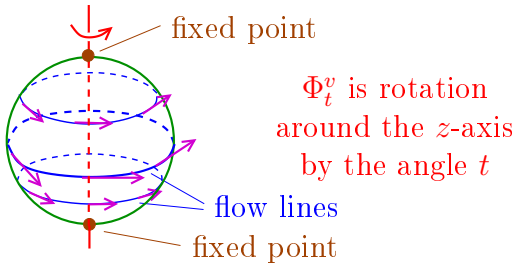
Definition. Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel.

(1) For each $P \in M$ we refer to the subset $\Phi^v(\{P\} \times \mathbb{R}) \subset M$ as a flow line.[354]
(2) For $t \in \mathbb{R}$ the map $\Phi^v_t \colon M \to M$ that is given by $P \mapsto \Phi^v(P, t)$ is called the time-t map of the flow.

Example. We consider S^2 together with the smooth vector field that is given by



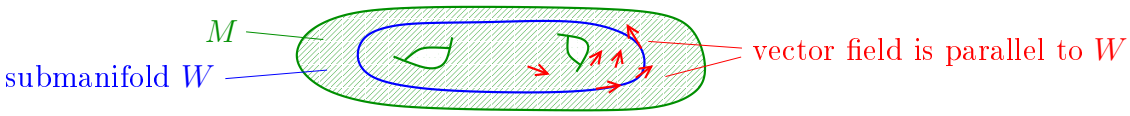
$$\begin{array}{rcl} v \colon S^2 & \to & \mathbb{R}^3 \\ (x, y, z) & \mapsto & (-y, x, 0). \end{array}$$



This vector field vanishes at the "North Pole" $(0, 0, 1)$ and at the "South Pole" $(0, 0, -1)$. By the Flow Theorem 35.1 this vector field gives rise to a complex v-flow $\Phi^v \colon S^2 \times \mathbb{R} \to S^2$. It is pretty straightforward to see that for any $t \in \mathbb{R}$ the corresponding time-t map $\Phi^v_t \colon S^2 \to S^2$ is just given by rotation around the z-axis by the angle t. In particular we see that the flow lines are the circles of latitude.

---

[353] Here and throughout this chapter we will use the convention from page 633 which says that given a smooth manifold M we can view the tangent spaces of the boundary ∂M and tangent spaces of submanifolds of M as vector subspaces of the tangent spaces $\mathrm{T}_P M$.



[354] We will not really make use of the concept of a flow line. But the concept will be useful in illustrations to draw pictures of flows.

Our next definition is a self-explanatory variation on the notion of a boundary parallel vector field.

Definition. Let M be a smooth manifold and let v be a vector field on M. Let W be a submanifold of M. We say v is parallel to the submanifold W if for each $P \in W$ we have $v(P) \in \mathrm{T}_P W$.

The following proposition summarizes a few properties of complete flows.

Proposition 35.2. (Flow-Diffeotopy Proposition) Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. We denote by $\Phi^v \colon M \times \mathbb{R} \to M$ the corresponding unique v-flow.

(1) For each $t \in \mathbb{R}$ the time-t map

$$\begin{array}{rccc} \Phi_t^v \colon & M & \to & M \\ & P & \mapsto & \Phi^v(P,t) \end{array}$$

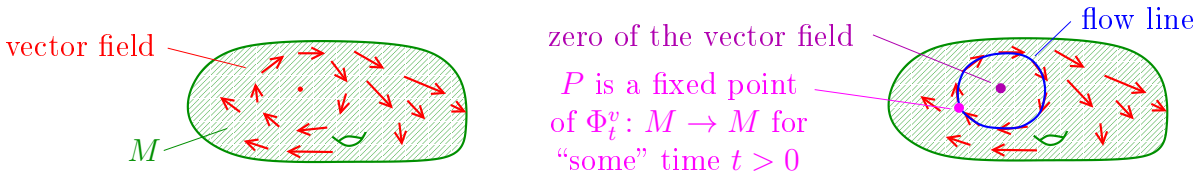
is a diffeomorphism.

(2) Suppose that $W \subset M$ is a proper submanifold. If v is parallel to W, then the map Φ^v restricts to a map $W \times \mathbb{R} \to W$ and this map is the unique complete flow of the vector field $v|_W$ on the smooth manifold W.

Proof. We postpone the proof of the Flow-Diffeotopy Proposition 35.2 to The next section, more precisely, to page 853. ■

We continue with the following definition that will pop up time and again throughout these notes.

Definition. Let S be some set and let $f \colon S \to S$ be a map. We say $P \in S$ is a fixed point of f if $f(P) = P$.



The following lemma says that zeros of vector fields give rise to fixed points of the time-t maps of the complete v-flows.

Lemma 35.3. Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. Let $\Phi^v \colon M \times \mathbb{R} \to M$ be the corresponding unique complete v-flow from the Flow Theorem 35.1. If P is a zero of the vector field, i.e. if $v(P) = 0$, then

for every $t \in \mathbb{R}$ we have $\Phi^v(P,t) = P$. Put differently, for every $t \in \mathbb{R}$ the point P is a fixed point of $\Phi^v_t \colon M \to M$.

Proof. This statement follows immediately from the uniqueness statement in the Fundamental Theorem 35.7 for Autonomous ODEs, applied to the map $t \mapsto \Phi^v(P,t)$ and the constant map $t \mapsto P$. ■

Now let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. Let $\Phi^v \colon M \times \mathbb{R} \to M$ be the corresponding unique complete v-flow from the Flow Theorem 35.1. If $P \in M$ is a point with $v(P) \neq 0$ it can of course still happen that there exists a $t \in \mathbb{R}$ such that $\Phi^v_t(P) = P$. For example let us consider the vector field v on S^2 that we studied on page 845. In this case we see that $\Phi^v_{2\pi} = \mathrm{id}_{S^2}$.

The following theorem says that if a vector field has no zeros, then at least for a short time period each time-t map is fixed-point free.

Theorem 35.4. (Flow Fixed Point Theorem) Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. Let $\Phi^v \colon M \times \mathbb{R} \to M$ be the corresponding unique complete v-flow from the Flow Theorem 35.1. If v has no zeros, then there exists an $\epsilon > 0$ such that for each $t \in (0, \epsilon]$ the map $\Phi^v_t \colon M \to M$ is fixed-point free. In other words, given any $t \in (0, \epsilon]$ and given any $P \in M$ we have $\Phi^v_t(P) \neq P$.

Proof. To keep the discussion of the main results as clean as possible we postpone the proof of the Flow Fixed Point Theorem 35.4 to page 854. ■

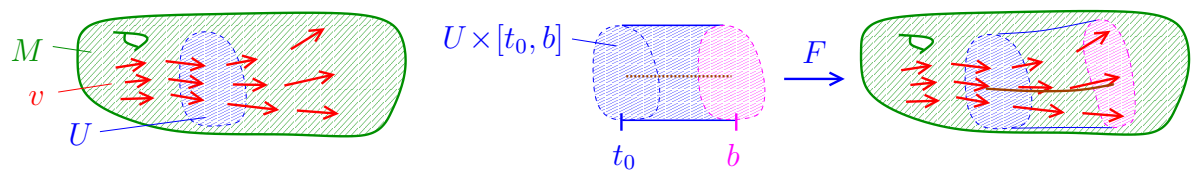
Remark.

(1) In the Replace-by-Smooth Vector Field Proposition 29.6 we showed that if a smooth manifold admits a nowhere-vanishing vector field[355], then it also admits a smooth nowhere-vanishing vector field.
(2) Later, in the Euler Characteristic-Vector Field Theorem 97.15, we will use the combination of the Flow Fixed Point Theorem 35.4 and the Flow-Diffeotopy Proposition 35.2 to show that every smooth vector field on a closed smooth manifolds with non-zero "Euler characteristic" has at least one zero.

Most of the remainder of this chapter is dedicated to the proofs of Flow Theorem 35.1 and the Flow Fixed Point Theorem 35.4. Only in the very last section we give one more application of the Flow Theorem 35.1. Readers who happen to be allergic to technical proofs are advised to move on either to Section 35.6 or straight to the next chapter.

[355] Recall that according to our definition on page 639 a vector field is by definition continuous, not more and not less.

35.2. **Proof of the Flow Theorem 35.1.** In this section we will provide the proof of Flow Theorem 35.1. We will use one major ingredient from real analysis, namely the Fundamental Theorem 35.7 for Autonomous ODEs. Besides this input we will provide all details.

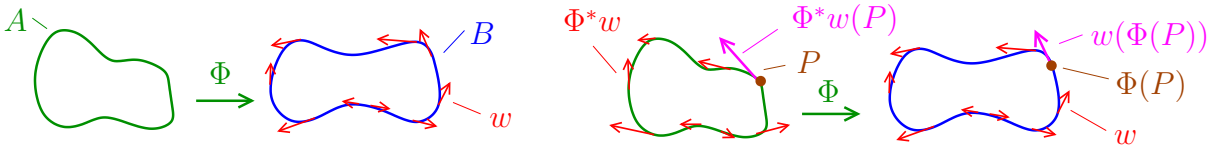


We start our discussion of the proof of the Flow Theorem 35.1 with the following sanity-preserving convention.

Convention. Given a smooth submanifold $U \subset \mathbb{R}^n$ we will use the Differential-equals-Differential Lemma 23.4 and the Tangent Space-Isomorphism Proposition 23.16 as an excuse for not distinguishing between the various notions of tangent spaces and differentials.

Throughout this section it is convenient to work with the following generalization of the notion of a complete flow.

Definition. Let M be a smooth manifold and let $t_0 \in \mathbb{R}$. A *v-flow based at t_0* consists of an open subset $U \subset M$ and an interval neighborhood I of t_0 together with a smooth map $F\colon U \times I \to M$ that satisfies the following properties:



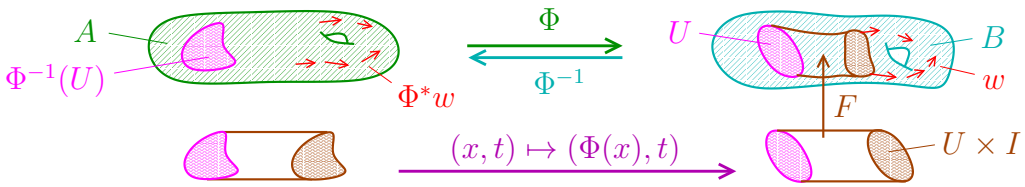
(1) For each $P \in U$ we have $F(P, t_0) = P$.
(2) For each $P \in U$ the map $I \to M$ that is given by $t \mapsto F(P,t)$ is a solution of the ODE $y' = v(y)$.

Notation. Let $\Phi\colon A \to B$ be a local diffeomorphism between two smooth manifolds and let w be a vector field on B. We denote by Φ^*w the vector field on A which assigns to each $P \in A$ the tangent vector

$$\Phi^*w(P) \;:=\; (\mathrm{D}\Phi_P)^{-1}(\underbrace{w(\Phi(P))}_{\in \mathrm{T}_{\Phi(P)}B}) \;\in\; \mathrm{T}_P A.$$

It follows easily from the definitions, and an argument say as in the proof of the Smooth-via-Atlas Lemma 19.21, that if w is a smooth vector field on B, then Φ^*w is a smooth vector field on A.

Lemma 35.5. Let $\Phi\colon A \to B$ and $\Psi\colon B \to C$ be local diffeomorphisms between smooth manifolds and let w be a vector field on C. Then $\Phi^*(\Psi^*w) = (\Psi \circ \Phi)^*w$.



Proof. This statement follows immediately from the chain rule of differentials, see the Tangent Space-Functor Proposition 23.10 (2). ∎

The following lemma allows us to reduce questions on flows via diffeomorphisms to settings which are hopefully easier.

Lemma 35.6. (Flow-Diffeomorphism Lemma) Let $\Phi\colon A \to B$ be a diffeomorphism between two smooth manifolds and let w be a vector field on B. Furthermore let $U \subset B$ be an open subset and let $t_0 \in \mathbb{R}$. If $F\colon U \times I \to B$ is a w-flow on B based at t_0, then the map

$$\begin{array}{rcl} \Phi^{-1}(U) \times I & \to & A \\ (x,t) & \mapsto & \Phi^{-1}(F(\Phi(x),t)) \end{array}$$

is a $\Phi^* w$-flow based at t_0.

Proof. Let $x \in \Phi^{-1}(U)$. First we calculate

$$\frac{d}{dt}\Phi^{-1}(F(\Phi(x),t)) \overset{\text{by the chain rule, see the Tangent Space-Functor Proposition 23.10}}{=} \left(\mathrm{D}\Phi_{\Phi^{-1}(F(\Phi(x),t))}\right)^{-1} \cdot \frac{d}{dt}F(\Phi(x),t)$$
$$\overset{\text{since } F \text{ is a } w\text{-flow}}{=} \left(\mathrm{D}\Phi_{\Phi^{-1}(F(\Phi(x),t))}\right)^{-1} \cdot w(F(\Phi(x),t)) \overset{\text{by definition of } \Phi^* w \text{ at the point } \Phi^{-1}(F(\Phi(x),t))}{=} \Phi^*(w)(\Phi^{-1}(F(\Phi(x),t))).$$

Finally note that for each $x \in \Phi^{-1}(U)$ we have

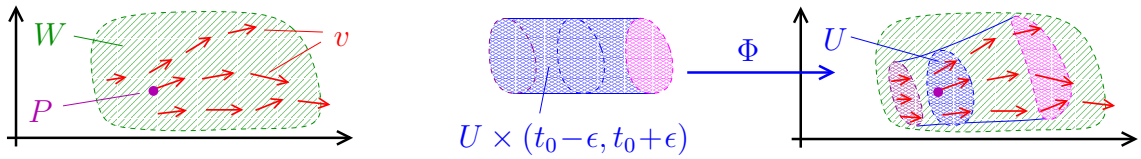
$$\Phi^{-1}(F(\Phi(x),t_0)) \overset{\text{since the } w\text{-flow } F \text{ is a based at } t_0}{=} \Phi^{-1}(\Phi(x)) = x.$$

We have thus verified that the given map is indeed a $\Phi^* w$-flow based at t_0. ∎

The Flow-Diffeomorphism Lemma 35.6 gives us the tool to reduce many of our problems to the setting of open subsets of $\mathbb{R}^n$. This is the right moment for rolling out the following major theorem from real analysis.

Theorem 35.7. (Fundamental Theorem for Autonomous ODEs) Let $W \subset \mathbb{R}^n$ be an open subset and let $v\colon W \to \mathbb{R}^n$ be a smooth map.

(1) Given any $P \in W$ and any $t_0 \in \mathbb{R}$ there exists an open neighborhood U of P in W and an open neighborhood I of t_0 such that for every $x \in U$ there exists a solution $\varphi\colon I \to W$ of the ODE $y' = v(y)$ with $\varphi(t_0) = x$.



(2) Let $I \subset \mathbb{R}$ be an open interval. Furthermore let $f\colon I \to W$ and $g\colon I \to W$ be two solutions of the ODE $y' = v(y)$. If there exists a $t_0 \in I$ with $f(t_0) = g(t_0)$, then $f(t) = g(t)$ for all $t \in I$.

(3) Let $U \subset W$ be an open subset, let $t_0 \in \mathbb{R}$ and let $I \subset \mathbb{R}$ be an open neighborhood of t_0. Suppose that for each $x \in U$ we are given a map $\varphi_x\colon I \to W$ that is a solution of the ODE $y' = v(y)$ and such that $\varphi_x(t_0) = x$. Then the map

$$\begin{array}{rcl} \Phi\colon U \times I & \to & W \\ (x,t) & \mapsto & \varphi_x(t) \end{array}$$

is smooth. In other words, Φ is a v-flow based at t_0.

(4) If $F\colon U \times I \to W$ and $G\colon V \times J \to W$ are two v-flows based at t_0, then F and G agree on the intersection of their domains.

Proof. The first three statements of the theorem get proved in every respectable course on ordinary differential equations. For example a proof is provided in [**Lee2002**, Theorem D.1]. The last statement is an immediate consequence of (2) and the convenient fact that the intersection of two intervals is again an interval. ■

Lemma 35.8. Let M be a smooth manifold and let v be a smooth vector field on M. Let $F\colon M \times (a,b) \to M$ be a v-flow based at 0.

(1) For every μ, ν with $\mu \in (a,b)$ and $\mu + \nu \in (a,b)$ we have

$$F(F(P,\mu),\nu) \;=\; F(P,\mu+\nu).$$

(2) For every $\mu \in \mathbb{R}$ with $-\mu \in I$ the maps

$$\begin{array}{rcl} M & \to & M \\ P & \mapsto & F(P,-\mu) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} M & \to & M \\ P & \mapsto & F(P,\mu) \end{array}$$

are diffeomorphisms and they are inverses of one another.

Proof.

(1) Let $P \in M$ and let $\mu \in (a,b)$. We consider the map

$$\begin{array}{rcl} \psi\colon (a-\mu, b-\mu) & \to & M \\ t & \mapsto & F(P,\mu+t). \end{array}$$

Note that for each $t \in (a-\mu, b-\mu)$ we have

$$\psi'(t) \underset{\substack{\uparrow \\ \text{chain rule}}}{=} F'(P,\mu+t)\cdot 1 \;=\; v(F(P,\mu+t)) \;=\; v(\psi(t)).$$

This shows that $t \mapsto \psi(t) = F(P,\mu+t)$ is a solution of the ODE $y' = v(y)$. Note that $\psi(0) = F(P,\mu)$. Another solution of the ODE $y' = v(y)$ with the same initial condition is given by $t \mapsto \varphi(t) := F(F(P,\mu),t)$. It follows from the Fundamental Theorem 35.7 for Autonomous ODEs (3) that $F(P,t+\mu) = \psi(t) = \varphi(t) = F(F(P,\mu),t)$ for all $t \in (a-\mu, b-\mu)$. But that is what we needed to show.

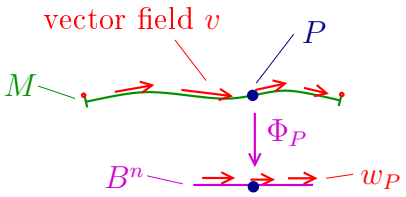
(2) Let $\mu \in \mathbb{R}$ with $-\mu \in I$. We consider the maps

$$\begin{array}{rcl} \alpha\colon M & \to & M \\ P & \mapsto & F(P,-\mu) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \beta\colon M & \to & M \\ P & \mapsto & F(P,\mu) \end{array}$$

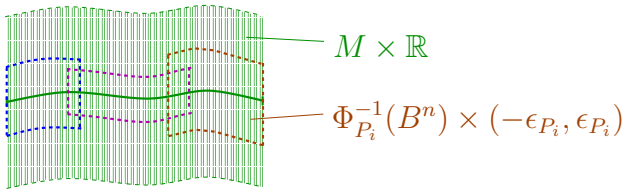
The map $F\colon M \times (a,b) \to M$ is a flow, in particular F is smooth. It follows easily from the Smooth Manifold Product Proposition 19.31 and Lemma 19.22 (2) that the two maps α and β are smooth. Thus it suffices to show that the maps α and β are inverses of one another. But this is an immediate consequence of (1). ■

Now we can finally provide the proof of the Flow Theorem 35.1. To improve readability we first deal with the case of smooth manifolds without boundary. Afterwards we will explain how one needs to adapt the argument to deal with smooth manifolds with non-empty boundary.

Proof of the Flow Theorem 35.1 if $\partial M = \varnothing$. Let M be a closed n-dimensional smooth manifold and let v be a smooth vector field on M. We need to show that there exists a unique complete v-flow on M. In fact the uniqueness follows almost immediately from the uniqueness statement of the Fundamental Theorem 35.7 for Autonomous ODEs together with the Flow-Diffeomorphism Lemma 35.6. Thus it remains to show the existence of a complete v-flow $\Phi\colon M \times \mathbb{R} \to M$.



Claim 1. Given any $P \in M$ there exists an open neighborhood A_P of $P \in M$, an $\epsilon_P > 0$ and a v-flow $F_P\colon A_P \times (-\epsilon_P, \epsilon_P) \to M$ based at 0.



Proof. Let $P \in M$. Since we assume that $\partial M = \varnothing$ we know that there exists a chart $\Phi_P\colon U_P \to B^n$ with $\Phi_P(P) = 0$. We consider the smooth vector field $w := (\Phi_P^{-1})^*(v)$ on B^n. Recall that we assume that v is a smooth vector field on M. By the definition of a smooth vector field on a smooth manifold, see page 639, this implies that w, viewed as a map $w\colon B^n \to \mathbb{R}^n$ is actually a smooth map. Therefore it follows from Statements (1) and (3) of the Fundamental Theorem 35.7 for Autonomous ODEs there exists an open neighborhood N_P of $0 \in B^n$, an $\epsilon_P > 0$ and a w-flow $G\colon N_P \times (-\epsilon_P, \epsilon_P) \times B^n$ based at 0. We set $A_P := \Phi^{-1}(N_P)$. The claim now follows from the Flow-Diffeomorphism Lemma 35.6 together with Lemma 35.5. ⊞

Claim 2. There exists an $\epsilon > 0$ and a v-flow $F\colon M \times (-\epsilon, \epsilon) \to M$ based at 0.

Proof. By hypothesis the smooth manifold M is closed, in particular M is compact. It follows that there exist finitely many points $P_1, \dots, P_k \in M$ such that $M = A_{P_1} \cup \dots \cup A_{P_k}$. We set $\epsilon := \min\{\epsilon_{P_1}, \dots, \epsilon_{P_k}\}$.

It follows easily from Statement (4) of the Fundamental Theorem 35.7 for Autonomous ODEs, together with the Flow-Diffeomorphism Lemma 35.6, that the flows $F_{P_1}, \dots, F_{P_k}$ agree on the overlaps of their domains. In particular these v-flows combine to give a v-flow $F\colon M \times (-\epsilon, \epsilon) \to M$ based at 0. ⊞

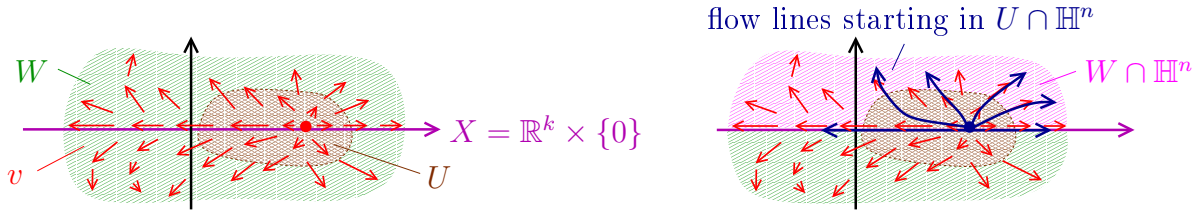
By Lemma 35.8 we know that $\Theta := F_{\frac{\epsilon}{2}}\colon M \to M$ is a diffeomorphism. For each $k \in \mathbb{Z}$ we consider the map

$$\begin{array}{rcl} \widetilde{F}_k\colon M \times (\frac{k\cdot\epsilon}{2} - \epsilon, \frac{k\cdot\epsilon}{2} + \epsilon) & \to & M \\ (P, t) & \mapsto & \Theta^k(F(\Theta^{-k}(P), t - \frac{k\cdot\epsilon}{2})). \end{array}$$

It follows again from the Fundamental Theorem 35.7 for Autonomous ODEs (4) together with the Flow-Diffeomorphism Lemma 35.6 that these v-flows agree on the overlap of their

domains. Thus these maps can be combined to define a v-flow $F\colon M \times \mathbb{R} \to \mathbb{R}$ that is based at 0. ■

The proof of the Flow Theorem 35.1 if $\partial M \neq \varnothing$ will build on the following lemma.



Lemma 35.9. Let $n \in \mathbb{N}$. We set $X := \mathbb{R}^k \times \{0\} \subset \mathbb{R}^n$. Let W be an open subset of $\mathbb{R}^n$ and let $v\colon W \to \mathbb{R}^n$ be a smooth vector field on W that is parallel to $W \cap X$, i.e. we assume that for every $P \in X$ we have $v(P) \in \mathrm{T}_P X = \mathbb{R}^k \times \{0\}$. Furthermore let $U \subset W$ be an open subset and let $F\colon U \times I \to W$ be a v-flow on U based at some t_0. Let $k \in \{0, \dots, n\}$.

(1) The map $F\colon W \times I \to U$ restricts to a map

$$F\colon (U \cap X) \times I \ \to \ W \cap X.$$

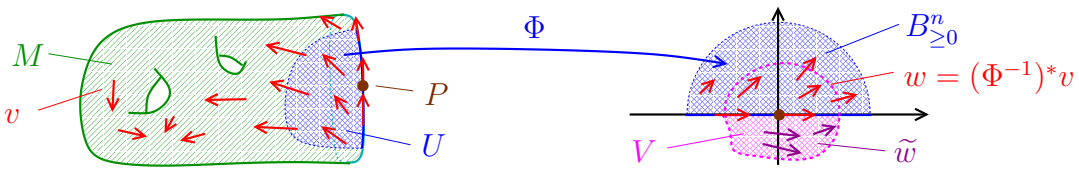
(2) If $k = n - 1$, then the map $F\colon W \times I \to U$ restricts to a map

$$F\colon (U \cap \mathbb{H}^n) \times I \ \to \ W \cap \mathbb{H}^n.$$

Proof. The first statement follows immediately from the Mean Value Theorem. The second statement follows from the first statement and the Intermediate Value Theorem. We leave it to the reader to fill in the details. ■

Proof of the Flow Theorem 35.1 if $\partial M \neq \varnothing$. Let M be a compact n-dimensional smooth manifold with (possibly) non-empty boundary and let v be a smooth vector field on M that is boundary parallel. As in the proof for closed smooth manifolds it suffices to prove the following claim.

Claim 2. There exists an $\epsilon > 0$ and a v-flow $F\colon M \times (-\epsilon, \epsilon) \to M$ based at 0.



Furthermore, as in the proof for closed smooth manifolds, this Claim 2 follows easily from the following Claim 1.

Claim 1. Given any $P \in M$ there exists an open neighborhood A of $P \in M$, an $\epsilon > 0$ and a v-flow $F\colon A \times (-\epsilon, \epsilon) \to M$ based at 0.

Proof. Let $P \in M$. If $P \in M \setminus \partial M$, then we apply the same argument as on page 851. Now let $P \in \partial M$. This implies that there exists a chart $\Phi\colon U \to B^n_{\geq 0}$ with $\Phi(P) = 0$. We consider the vector field $w := (\Phi^{-1})^*(v)$ on $B^n_{\geq 0}$.

Since v is a smooth vector field on M we see, by the definition of a smooth vector field on a smooth manifold on page 639, that $(\Phi^{-1})^* v\colon B^n_{\geq 0} \to \mathbb{R}^n$ is a smooth map. By definition of a smooth map on $B^n_{\geq 0}$, see page 532, there exists an open neighborhood V of $0 \in \mathbb{R}^n$ and a smooth vector map $\widetilde{w}\colon V \to \mathbb{R}^n$ such that $\widetilde{w}$ and $(\Phi^{-1})^* v$ agree on the common subset $V \cap B^n_{\geq 0}$.

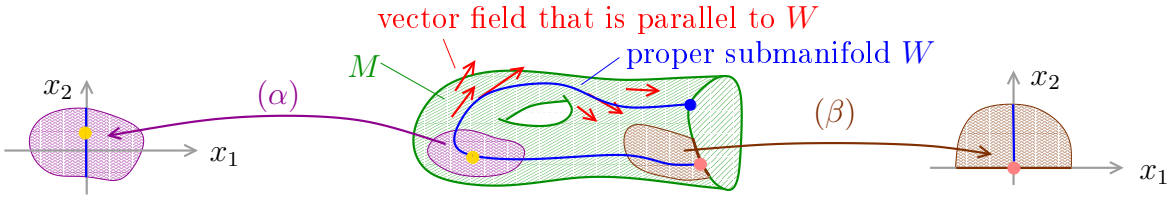
It follows again from Statements (1) and (3) of the Fundamental Theorem 35.7 for Autonomous ODEs that there exists an open neighborhood N of $0 \in V$, an $\epsilon > 0$ and a $\widetilde{w}$-flow $G\colon N \times (-\epsilon, \epsilon) \to V$ based at 0. Next note that it follows from our hypothesis that v is boundary parallel, together with Lemma 35.9, that the map G restricts to a map

$G\colon (N \cap B^n_{\geq 0}) \times (-\epsilon, \epsilon) \to V \cap B^n_{\geq 0}$. We set $A := \Phi^{-1}(N \cap B^n_{\geq 0})$. The desired statement now follows from the Flow-Diffeomorphism Lemma 35.6 together with Lemma 35.5. ■

Finally, with all the tools that we have acquired by now the proof of the Flow-Diffeotopy Proposition 35.2 is only a formality.

Proof of the Flow-Diffeotopy Proposition 35.2. Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. Let $\Phi^v\colon M \times \mathbb{R} \to M$ be the corresponding complete v-flow.

(1) Let $t \in \mathbb{R}$. We need to show that the map $\Phi^v_t\colon M \to M$ is a diffeomorphism that is diffeotopic to the identity. To do so we consider the map



$$\begin{array}{rcl} H\colon M \times [0,1] & \to & M \\ (P, s) & \mapsto & \Phi^v(P, t \cdot s). \end{array}$$

Since $\Phi^v\colon M \times \mathbb{R} \to M$ is a v-flow we know that $\Phi^v\colon M \times \mathbb{R} \to M$ is in particular smooth. It follows that $H\colon M \times [0,1] \to M$ is smooth. Furthermore by Lemma 35.8 we know that each $H_s\colon M \to M$ is a diffeomorphism. This shows that H is a diffeotopy.

(2) Suppose that $W \subset M$ is a proper submanifold and suppose that v is parallel to W. We need to show that the map $\Phi^v\colon M \times \mathbb{R} \to M$ restricts to a map $W \times \mathbb{R} \to W$ and that this map is the unique complete flow of the vector field $v|_W$ on W. Recall that by the definition of a proper submanifold, see page 525, W is a closed subset of M and for each $P \in M$ we can find submanifold charts of type (α) or (β) as defined on page 525 and as illustrated in the figure below. Given $P \in W$ we consider the map

$$\begin{array}{rcl} \varphi\colon \mathbb{R} & \to & M \\ t & \mapsto & \Phi^v(P, t). \end{array}$$

It follows from Lemma 35.9 together with the Flow-Diffeomorphism Lemma 35.6 that $\varphi^{-1}(W)$ is an open subset of $\mathbb{R}$. Since W is a closed subset of M we know that $\varphi^{-1}(W)$ is a closed subset of $\mathbb{R}$. Since $\varphi(0) = P$ we see that $\varphi(W) \neq \varnothing$. By the Path-Connected Implies Connected Corollary 2.23 we know that $\mathbb{R}$ is connected. Thus we see that $\varphi^{-1}(W) = \mathbb{R}$. But this implies that $\Phi^v(W \times \mathbb{R}) \subset W$. Finally it follows from the uniqueness statement of the Flow Theorem 35.1 that $\Phi^v|_{W \times \mathbb{R}}$ is indeed the complete $v|_W$-flow. ■

35.3. **Proof of the Flow Fixed Point Theorem 35.4.** For the reader's convenience we recall the Flow Fixed Point Theorem 35.4.

Theorem 35.4. (Flow Fixed Point Theorem) Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel. Let $\Phi^v\colon M\times\mathbb{R}\to M$ be the unique complete v-flow $\Phi^v\colon M\times\mathbb{R}\to M$ from the Flow Theorem 35.1. If v has no zeros, then there exists an $\epsilon>0$ such that for each $t\in(0,\epsilon]$ the time t-map $\Phi^v_t\colon M\to M$ is fixed-point free. In other words, given any $t\in(0,\epsilon]$ and given any $P\in M$ we have $\Phi^v_t(P)\neq P$.

Remark. We will give a bare hands proof of Flow Fixed Point Theorem 35.4. A more elegant proof can also be given using Proposition 35.11.

Our proof rests on the following auxiliary lemma.

Auxiliary Lemma 35.10. Let I be an interval and let $\varphi\colon I\to U$ be a smooth map. If there exists a linear map $\pi\colon\mathbb{R}^n\to\mathbb{R}$ such that for every $t\in I$ we have $\pi(\varphi'(t))>0$, then φ is injective.

Proof of Lemma 35.10. We consider the map $\pi\circ\varphi\colon I\to\mathbb{R}$. Note that for every $t\in I$ we have

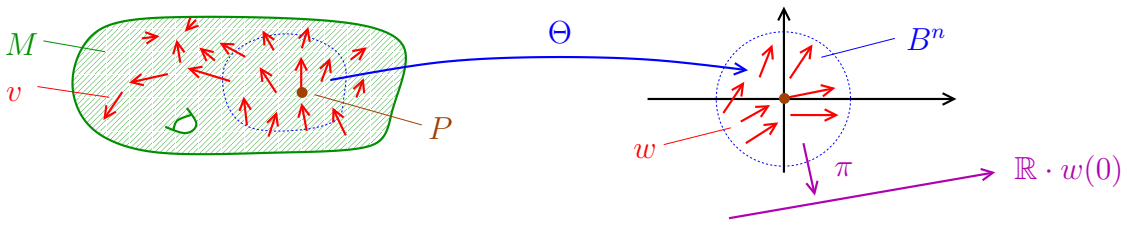
$$\begin{array}{ccccc}(\pi\circ\varphi)'(t) & = & \mathrm{D}\pi_{\varphi(t)}(\varphi'(t)) & = & \pi(\varphi'(t)) \\ & \uparrow & & \uparrow & \uparrow \\ & \text{by the Chain Rule 19.10} & & \text{see page 536} & \text{by hypothesis}\end{array} \quad > \quad 0.$$

It follows from elementary real analysis that $\pi\circ\varphi$ is injective. But this implies of course that $\varphi\colon I\to U$ is injective. ■

Proof of the Flow Fixed Point Theorem 35.4. Let M be a compact smooth manifold and let v be a smooth vector field on M that is boundary parallel and which has no zeros. We denote by $\Phi^v\colon M\times\mathbb{R}\to M$ the corresponding unique complete v-flow.

Claim. For each $P\in M$ there exists an open neighborhood U_P of P and an $\epsilon_P>0$ such that for every $x\in U_P$ the map $(-\epsilon_P,\epsilon_P)\to M$ given by $t\mapsto\Phi^v(x,t)$ is injective.

Proof. Let $P\in M$. In the following we deal with the case that $P\in M\setminus\partial M$. The case $P\in\partial M$ is deal with in a very similar fashion.



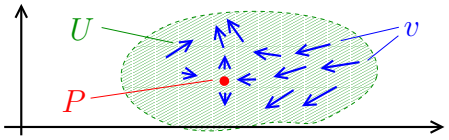
It follows easily from the hypothesis that $v(P)\neq 0$ that there exists a chart $\Theta\colon U\to B^n$ around P such that $\Phi(P)=0$ and such that $w:=(\Theta^{-1})^*v$ has the property that for each $x\in B^n$ we have $\|w(x)-w(0)\|<\frac{1}{2}\cdot\|w(0)\|$.

Since U is an open subset of M we obtain from the continuity of Φ^v that $\Phi^v(U)\subset M\times\mathbb{R}$ is an open neighborhood of $(P,0)$. Thus there exists an open neighborhood U_P of P and an $\epsilon_P>0$ such that $\Phi^v(U_P\times(-\epsilon_P,\epsilon_P))\subset U$.

Recall that $w(0)\neq 0$. Let $\pi\colon\mathbb{R}^n\to\mathbb{R}$ be the linear map that corresponds to the orthogonal projection onto $\mathbb{R}\cdot w(0)$. Since $\|w(x)-w(0)\|<\frac{1}{2}\cdot\|w(0)\|$ for all $x\in B^n$ we obtain from an elementary calculation that $\pi(w(x))>0$ for all $x\in B^n$. It follows from Lemma 35.10 that for each $x\in\Theta(U_P)$ the map

$$\begin{array}{ccc}(-\epsilon_P,\epsilon_P) & \to & B^n \\ x & \mapsto & \Theta(\Phi^v(\Theta^{-1}(x),t))\end{array}$$

is injective. This shows that ϵ_P together with the open neighborhood U_P of P has the desired properties. ⊞



Since M is compact there exist $P_1, \dots, P_k \in M$ with $U_{P_1} \cup \dots \cup U_{P_k} = M$. It is clear that $\epsilon := \min\{\epsilon_{P_1}, \dots, \epsilon_{P_k}\}$ has the desired properties. ■

35.4. **Appendix I: Zeros of vector fields.** In this first appendix to this chapter we state a proposition which gives us information about the flow of a vector field near a zero of the vector field. We will not make use of it. But perhaps readers, who want to extend some of the earlier results, will find it useful.

Proposition 35.11. Let $U \subset \mathbb{R}^n$ be an open subset, let $v\colon U \to \mathbb{R}^n$ be a smooth vector field on U and let P be a zero of v. Furthermore let W be an open neighborhood of P and let $F\colon W \times (-\epsilon, \epsilon) \to U$ be a v-flow based at 0. Then for every $t \in (-\epsilon, \epsilon)$ we have[356]

$$\mathrm{D}(F_t)_P \;=\; \exp(t \cdot \mathrm{D}v_P).$$

Here, for a matrix $A \in \mathrm{M}(n \times n, \mathbb{R})$ we write $\exp(A) := \sum_{k=0}^{\infty} \frac{A^k}{k}$.

$$\mathrm{D}v_P = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$$

Proof. The fact that P is a zero of v implies by Lemma 35.3 that $F(P,t) = P$ for all $t \in (-\epsilon, \epsilon)$. Therefore it follows from [**PW2019**, Satz 4.3.1], after some slight unraveling of the definitions, that the map

$$\begin{array}{rcl} (-\epsilon, \epsilon) & \to & \mathrm{M}(n \times n, \mathbb{R}) \\ t & \mapsto & \mathrm{D}(F_t)_P \end{array}$$

satisfies the ODE

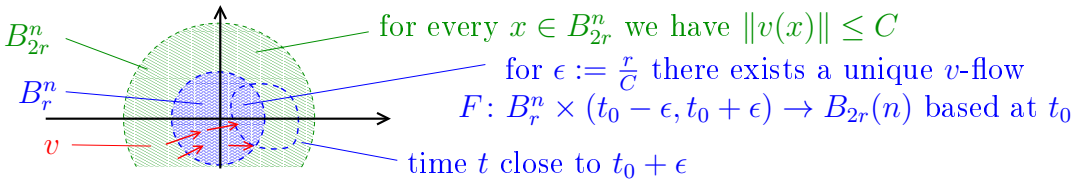
$$y' \;=\; \mathrm{D}v_P \cdot y.$$

But by [**PW2019**, p. 58] this means that $\mathrm{D}(F_t)_P = \exp(t \cdot \mathrm{D}v_P)$ for every $t \in (-\epsilon, \epsilon)$. ■

35.5. **Appendix II: Dealing with non-compact smooth manifolds.** Let M be a smooth manifold and let v be a smooth vector field on M that is boundary parallel. As we saw on page 844, if M is non-compact, then there does not necessarily exist a complete v-flow $\Phi^v\colon M \times \mathbb{R} \to M$. If one wants to show that such a complete v-flow exists after all one needs some restrictions on the vector fields under consideration. In this appendix we will sketch one approach. We will not make use of the results of this appendix.

The proof of the Flow Theorem 35.1 was based on Statement (1) of the Fundamental Theorem 35.7 for Autonomous ODEs which says that if $W \subset \mathbb{R}^n$ be an open subset and if $v\colon W \to \mathbb{R}^n$ is a smooth map, then given any $P \in W$ and any $t_0 \in \mathbb{R}$ there exists an open

[356] Since $v(P) = 0$ we see in Lemma 35.3 that P is a fixed point of every F_t. Hence $\mathrm{D}(F_t)_P$ is an automorphism of $\mathrm{T}_P U = \widetilde{\mathrm{T}}_P U = \mathbb{R}^n$. In other words, it is given by a matrix in $\mathrm{M}(n \times n, \mathbb{R})$.



neighborhood U of P in W and an open neighborhood I of t_0 such that for every $x \in U$ there exists a solution $\varphi\colon I \to W$ of the ODE $y' = v(y)$ with $\varphi(t_0) = x$.

To deal with non-compact smooth manifolds we will need the following quantitative version of Statement (1) of the Fundamental Theorem 35.7 for Autonomous ODEs.

Proposition 35.12. Let $r > 0$ and let $v\colon B^n_{2r} \to \mathbb{R}^n$ be a smooth vector field on the open n-ball $B^n_{2r} \subset \mathbb{R}^n$ of radius $2r$. Suppose that we have a $C > 0$ such that for every $x \in B^n_{2r}$ we have $\|v(x)\| \leq C$. We set $\epsilon := \frac{r}{C}$.

(1) For every $x_0 \in B^n_r$ and every $t_0 \in \mathbb{R}$ there exists a solution $\varphi\colon (t_0 - \epsilon, t_0 + \epsilon) \to B^n_{2r}$ of the ODE $y' = v(y)$ with $\varphi(t_0) = x_0$.

(2) For every $t_0 \in \mathbb{R}$ there exists a unique v-flow $F\colon B^n_r \times (t_0 - \epsilon, t_0 + \epsilon) \to B^n_{2r}$ based at t_0.

Proof. Note that Statement (2) is an immediate consequence of Statement (1) together with Statements (3) and (4) of the Fundamental Theorem 35.7 for Autonomous ODEs. Thus it suffices to prove Statement (1).

We set $\epsilon := \frac{r}{C}$. Let $x_0 \in B^n_r$ and $t_0 \in \mathbb{R}$. In the following we will show that there exists a solution to the ODE $y' = v(y)$ with initial condition $\varphi(t_0) = y_0$ that is defined on $[t_0, t_0 + \epsilon)$. Basically the same argument can then be used to get the extension "to the left", i.e. to the interval $(t_0 - \epsilon, t_0]$. We consider

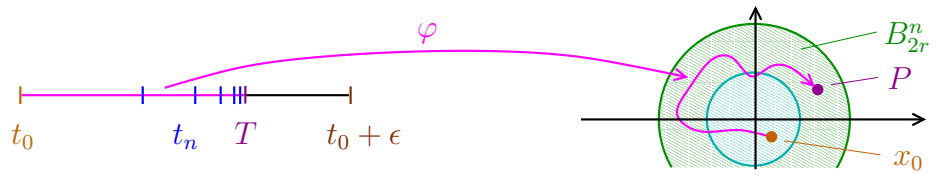
$$T := \sup\left\{ t \in (t_0, \infty) \;\middle|\; \begin{array}{c} \text{there exists a solution } \varphi\colon [t_0, t) \to B^n_{2r} \text{ of} \\ \text{the ODE } y' = v(y) \text{ with } \varphi(t_0) = x_0 \end{array} \right\}.$$

If $T > t_0 + \epsilon$ then we are evidently done. If $T = t_0 + \epsilon$, then for every $a \in (t_0, T)$ there exists a solution φ_a. But by Statement (2) of the Fundamental Theorem 35.7 for Autonomous ODEs we know that for any $b > a$ we have $\varphi_b|_{[t_0,a)} = \varphi_a$. This shows that these maps φ_a combine to define a solution φ on all of $[t_0, T) = [t_0, t_0 + \epsilon)$.

Finally suppose that $T < t_0 + \epsilon$. As in the previous paragraph we see that there exists a solution $\varphi\colon [t_0, T) \to B^n_{2r}$. Note that by Statement (2) of the Fundamental Theorem 35.7 for Autonomous ODEs we know at least that $T > t_0$.

Claim. The limit $P := \lim_{t \to T} \varphi(t)$ exists and it lies in B^n_{2r}.

Proof. We start with a little inequality, namely given $x, y \in [t_0, T)$ we have



$$\|\varphi(y) - \varphi(x)\| \underset{\text{Fundamental Theorem of Calculus}}{=} \left\| \int_x^y \varphi'(s)\, ds \right\| \overset{\text{Integral Inequality Lemma 0.16}}{\leq} \int_x^y \|\varphi'(s)\|\, ds \underset{\text{since } \varphi \text{ is a solution of the ODE } y' = v(y)}{=} \int_x^y \|v(\varphi(s))\|\, ds \underset{\text{since } \varphi \text{ takes values in } B^n_{2r} \text{ we have } \|v(\varphi(s))\| \leq C}{\leq} |y - x| \cdot C.$$

We pick a monotonously increasing sequence $(t_n)_{n\in\mathbb{N}}$ in $[t_0, T)$ with $\lim_{n\to\infty} t_n = T$. It follows from the above inequality that $(\varphi(t_n))_{n\in\mathbb{N}}$ is a Cauchy sequence in B^n_{2r}. We denote by $P \in \mathbb{R}^n$ its limit. It follows easily from the above inequality that in fact $\lim_{t\to T} \varphi(t) = P$. It remains to show that P actually lies in B^n_{2r}. This follows from the following (in-) equalities:

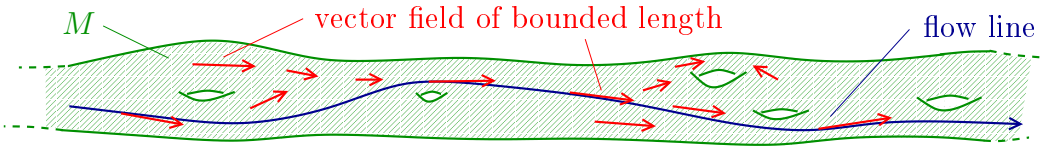
$$\|P\| \leq \|x_0\| + \|P - x_0\| = r + \left\| \lim_{t\to T} (\varphi(t) - \varphi(t_0)) \right\| \underset{\uparrow}{\leq} r + (T - t_0)\cdot C \underset{\uparrow}{<} r + \epsilon \cdot \frac{r}{\epsilon} = 2r.$$

by the above inequality we have $\|\varphi(t) - \varphi(t_0)\| \leq (t - t_0)\cdot C$

since $T < t_0 + \epsilon$ and since $\epsilon = \frac{r}{C}$ ⊞

Since P is contained in the open set B^n_{2r} it follows from Statement (1) of the Fundamental Theorem 35.7 for Autonomous ODEs that there exists an open neighborhood A of $P \in B^n_{2r}$, an open interval $(-\mu, \mu)$ and a v-flow

$$F\colon A \times (-\mu, \mu) \;\to\; B^n_{2r}$$



that is based at 0. Since $P = \lim_{t\to T} \varphi(t)$ and since A is an open neighborhood of U there exists a $t' \in (t_0, T)$ with $t' > T - \frac{\mu}{2}$ and with $\varphi(t') \in A$. We consider the map

$$\begin{array}{rcl} \psi\colon [t_0, t' + \mu) & \to & B^n_{2r} \\ s & \mapsto & \begin{cases} \varphi(s), & \text{if } s \in (t_0, T) \\ F(\varphi(t'), s - t'), & \text{if } s \in (t' - \mu, t' + \mu) \end{cases} \end{array}$$

Note that $s \mapsto \varphi(s)$ and $s \mapsto F(\varphi(t'), s - t')$ are both solutions to the ODE $y' = v(y)$ with $t' \mapsto \varphi(t')$. Thus it follows from Statement (2) of the Fundamental Theorem 35.7 for Autonomous ODEs that these two maps agree on the common domain, in other words, the above map ψ is in fact unambiguously defined. By construction it is a solution to the ODE $y' = v(y)$ with $\psi(t_0) = x_0$. Since $t + \mu > T - \frac{\mu}{2} + \mu > T$ we have obtained a contradiction to the assumption that $T < t_0 + \epsilon$. ■

Using Proposition 35.12 one can prove the following variation on the Flow Theorem 35.1.

Theorem 35.13. (Flow Theorem for Non-Compact Smooth Manifolds) Let M be a proper n-dimensional smooth submanifold of $\mathbb{R}^m$ and let v be a smooth vector field on M. If there exists a $C \in \mathbb{R}$, such that for each $x \in M$ we have $\|v(x)\| \leq C$, then there exists a unique complete v-flow $\Phi^v\colon M \times \mathbb{R} \to M$.

Proof. We leave the proof of the theorem as Project 35.2 to the reader. ■

35.6. **Moving points on smooth manifolds.** As a treat to the reader who made it that far we conclude this chapter with a neat application of the Flow Theorem 35.1, namely we can now give a new proof of Proposition 33.12 (2).

Proposition 35.14. Given any two points $P, Q \in \overline{B}^n \setminus \partial\overline{B}^n$ we can move P to Q in the sense of the definition on page 822.

Proof. Let $P, Q \in \overline{B}^n \setminus \partial\overline{B}^n$.

Claim. There exists a smooth vector field v on $\overline{B}^n$ which has the following two properties:
(1) The vector field vanishes on an open neighborhood of $\partial\overline{B}^n$.
(2) For every $t \in [0,1]$ we have $v(P \cdot (1-t) + t \cdot Q) = Q - P$.

Proof. We use Condition (2) as a definition of the vector field v on the line segment $\{P \cdot (1-t) + t \cdot Q \,|\, t \in [0,1]\}$. Since $P, Q \in \overline{B}^n \setminus \partial\overline{B}^n$ there exists an $\epsilon > 0$ such that this line segment is contained in $\overline{B}^n_{1-\epsilon}$. On $\overline{B}^n \setminus B^n_{1-\frac{\epsilon}{2}}$ we define v to be the zero vector field. We have thus defined v on a closed subset of $\overline{B}^n$. It is straightforward to show that v is smooth in the sense of the definition on page 532. Thus it follows from the Smooth Extension Proposition 21.9 that we can extend v to a smooth map $\overline{B}^n \to \mathbb{R}^n$. ⊞

Note that the vector field is in particular parallel to the boundary. Thus it follows from the Flow Theorem 35.1 that there exists a complete v-flow $\Phi^v \colon \overline{B}^n \times \mathbb{R} \to \overline{B}^n$. It follows easily from the uniqueness statement of the Fundamental Theorem 35.7 for Autonomous ODEs that $\Phi_1(P) = Q$ and that restriction of each Φ^v_t to $\overline{B}^n \setminus B^n_{1-\frac{\epsilon}{2}}$ is the identity.

As in the proof of the Flow-Diffeotopy Proposition 35.2 we see that it follows from Lemma 35.8 that the map

$$\begin{array}{rcl} H \colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,s) & \mapsto & \Phi^v(x,s) \end{array}$$

is a diffeotopy. From the above discussion it is clear that it has all the desired properties. ■

Exercises for Chapter 35.

Exercise 35.1. Let M be a smooth submanifold of $\mathbb{R}^n$ and let v be a "time dependent smooth vector field", i.e. let $v \colon M \times \mathbb{R} \to \mathbb{R}^n$ be a smooth map such that each $v_t \colon M \to \mathbb{R}^n$ is a smooth vector field on M.

- Let I be an interval with non-empty interior. We say a smooth map $\varphi \colon I \to M$ is a *solution of the ODE* $y' = v(y,t)$ if for every $t \in I$ we have the following equality:
$$\varphi'(t) \;=\; v(\varphi(t), t) \;\in\; \mathrm{T}_{\varphi(t)}M.$$
- A *complete v-flow* is a smooth map $F \colon M \times \mathbb{R} \to M$ that satisfies the following properties:
(a) For each $P \in M$ we have $F(P,0) = P$.

(b) For each $P \in M$ the map $\mathbb{R} \to M$ given by $t \mapsto F(P,t)$ is a solution of the ODE $y' = v(y,t)$.

Now suppose that M, viewed as a smooth manifold, is closed. Show that there exists a complete v-flow?

Exercise 35.2. Give an example of a vector field v on a closed smooth manifold that has only finitely man zeros and such there exists no $t > 0$ such that the map

$$\begin{array}{ccc} M & \to & M \\ P & \mapsto & \Phi^v(P,t) \end{array}$$

has infinitely many fixed-points.

Exercise 35.3. Let M be a compact smooth manifold.

(a) Let v be a smooth vector field on M that is boundary parallel. As usual we denote by $\Phi^v \colon M \times \mathbb{R} \to M$ the corresponding complete v-flow that exists by the Flow Theorem 35.1. Show that for every $s,t \in \mathbb{R}$ we have

$$\Phi^v_s \circ \Phi^v_t \;=\; \Phi^v_{s+t} \colon M \;\to\; M.$$

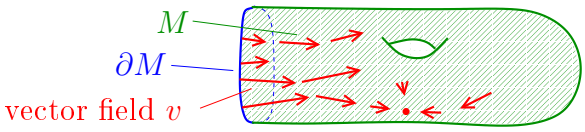
(b) We suppose that M is non-empty and that $\dim(M) > 0$. As on page 830 we denote by $\mathrm{Diff}(M)$ the group of self-diffeomorphism of M. Show that there exists a monomorphism $\mathbb{R} \to \mathrm{Diff}(M)$.

Exercise 35.4. We consider the smooth manifold $M = \mathbb{R}$. Does every smooth vector field v on M admit a complete v-flow?

Exercise 35.5. Use the Flow Theorem 35.13 to give a new proof of the Diffeotopies-of-S^1-Classification Proposition 34.5. More precisely, let $f \colon S^1 \to S^1$ be a diffeomorphism, show that the following two statements hold:

(1) If f is orientation-preserving, then f is diffeotopic to the identity.
(2) If f is orientation-reversing, then f is diffeotopic to the reflection $\rho \colon S^1 \to S^1$ that is given by $(x,y) \mapsto (x,-y)$.

Project 35.1. Let M be a compact smooth manifold.



(a) Show that there exists a smooth vector field v on M such that for every $x \in \partial M$ the vector $v(x) \in \mathrm{T}_x M$ points inward in the sense of the definition on page 620.
Hint. Use partitions of unity.

(b) Show that there exists an $\epsilon > 0$ and a smooth map $F \colon \partial M \times [0,1] \to M$ such that for every $x \in M$ the following two statements hold:
(a) $F(x,0) = x$,
(b) for every $t_0 \in [0,1]$ we have $\frac{d}{dt}(t \mapsto F(x,t))|_{t=t_0} = v(F(x,t_0))$.

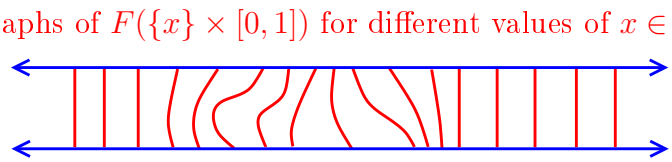
(c) Show that there exists a $\mu \in (0,\epsilon)$ such that $F \colon \partial M \times [0,\mu] \to M$ is a smooth embedding.
Hint. Use the Neighborhood Smooth Embedding Theorem 21.13.
Remark. This gives a new proof of the Smooth Collar Neighborhood Theorem 28.3 for smooth manifolds with compact boundary.

For readers with an insatiable appetite we have an extra exercise:

(d) Reprove the Smooth Collar Neighborhood Theorem 28.3 also for smooth manifolds with non-compact boundary.

Project 35.2. Prove the Flow Theorem 35.13 for Non-Compact Smooth Manifolds.

36. The Isotopy Extension Theorem



36.1. **The statement of the Isotopy Extension Theorem.** First let us recall the following definition from pages 419 and 822.

Definition. Let X and Y be topological spaces and let $F\colon X \times [0,1] \to Y$ be a homotopy.

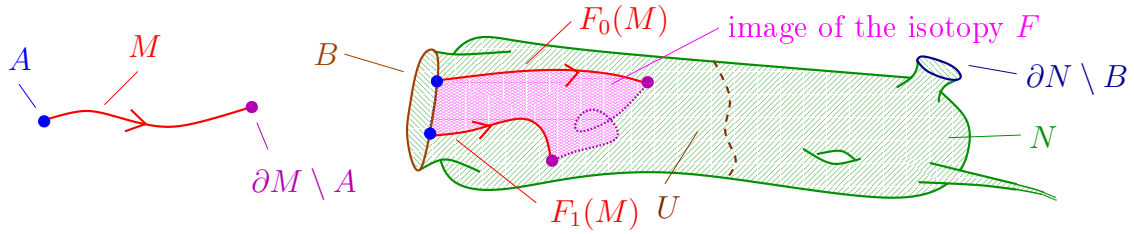
(1) Let $A \subset X$ be a subset. We say F is a homotopy rel A if for all $x \in A$ and $s, t \in [0,1]$ we have $F(x,s) = F(x,t)$.
(2) If $X = Y$, then we say F has compact support if there exists a compact subset $K \subset X$ such that $F(x,t) = x$ for all $x \notin K$ and all $t \in [0,1]$.

Examples.

(1) Evidently every diffeotopy of a compact smooth manifold has compact support.
(2) The diffeotopy $F\colon \mathbb{R} \times [0,1] \to \mathbb{R}$ given by $F(x,t) = x + t$ does *not* have compact support.
(3) In the figure below we sketch a non-trivial diffeotopy of $\mathbb{R}$ with compact support.

The following theorem is one of the key technical tools for dealing with smooth manifolds and their submanifolds.

Theorem 36.1. (Isotopy Extension Theorem) Let M be a compact smooth manifold and let N be a smooth manifold. Let A be a union of components of ∂M and let B be a union of components of ∂N. Let $F\colon M \times [0,1] \to N$ be a smooth isotopy that is trivial near the ends[357] and with the following property:



($*$) For each $t \in [0,1]$ we have $F_t(A) \subset B$ and we have $F_t(\partial M \setminus A) \subset N \setminus \partial N$.

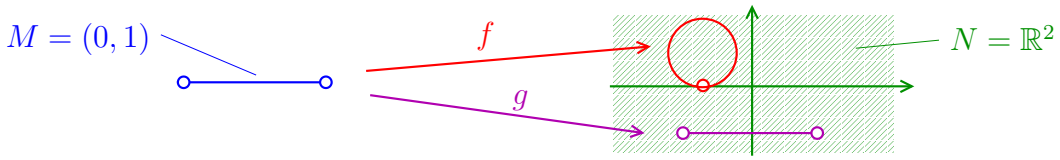
Furthermore suppose that we are given an open subset U of N with $F(M \times [0,1]) \subset U$. Then there exists a diffeotopy $G\colon N \times [0,1] \to N$ with the following properties:

(1) $G_0 = \mathrm{id}$.
(2) We have $G \circ (F_0 \times \mathrm{id}) = F\colon M \times [0,1] \to N$, in other words, we have
$$G(F_0(x), t) \;=\; F(x,t) \quad \text{for all } x \in M \text{ and } t \in [0,1].$$
(3) (a) G is a diffeotopy rel $N \setminus U$.
(b) G is a diffeotopy rel some neighborhood of $\partial N \setminus B$.
(c) G has compact support.
(d) G is trivial near the ends.

Proof. We procrastinate a bit and provide the proof in later sections. More precisely, in Sections 36.3 and 36.4 we will prove the Isotopy Extension Theorem 36.1 in the special case that M and N are closed smooth manifolds. The general case is dealt with in Section 36.5. ∎

[357] By the Trivial-Near-The-Ends-Lemma 33.4 we know that any smooth isotopy $F\colon M \times [0,1] \to N$ can be modified easily to obtain a smooth isotopy $\widetilde{F}\colon M \times [0,1] \to N$ that is trivial near the ends.

Remark.



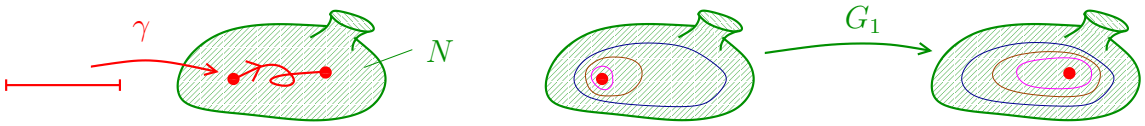
(1) Our proof of the Isotopy Extension Theorem 36.1 is modelled on the proofs of Theorem 2.4.2 and Theorem 2.4.6 of [**Wall2016**]. Our statement is somewhat more general though than the corresponding statements in [**Wall2016**] since we allow maps that take values in ∂N. We also refer to [**Kos1993**, Theorem II.5.2], [**Hirs1961**, Theorem 8.1.3] and [**Pal1960b**, Chapter 6] for related results.

(2) Note that there is a version of the Isotopy Extension Theorem 36.1 for topological manifolds and for "PL manifolds". We refer to [**EKi1971**, Corollary 1.4] and [**FNOP2019**, Theorem 2.10] respectively to [**RS1972**, Theorem 4.24] for details. In both cases one should carefully read the statements before applying them. We have no intention of making use of these results.

Example.

(1) Let N be a smooth manifold. The Isotopy Extension Theorem 36.1 often gets applied as follows: M is a (proper) submanifold in N and we start out with the inclusion map $i\colon M \to N$. Thus in this setting loosely speaking the Isotopy Extension Theorem 36.1 says, that if we deform M in N via (proper) submanifolds, then we can do so by "dragging N" along.

(2) In the statement of the Isotopy Extension Theorem 36.1 it is essential that M is compact. For example, let us consider the two smooth embeddings $f, g\colon (0,1) \to \mathbb{R}^2$ that are shown in the figure below. In Exercise 36.5 we will see that f and g are smoothly isotopic but we will also see that there is no diffeotopy $G\colon \mathbb{R}^2 \times [0,1] \to \mathbb{R}^2$ with $G_0 = \mathrm{id}$ and $G_1 \circ f = g$. Another, even more subtle example, will be studied in Exercise 36.9.



To formulate our last example of this section we need to introduce the following definition.

Definition. Let N be a smooth manifold and let $\gamma\colon [0,1] \to N$ be a smooth path. We say γ is trivial near the ends if there exists an $\epsilon > 0$ such that for each $t \in [0, \epsilon]$ we have $\gamma(t) = \gamma(0)$ and if for each $t \in [1-\epsilon, t]$ we have $\gamma(t) = \gamma(1)$.[358]

[358] As so often it follows from the Trivial-Near-The-Ends-Lemma 33.4 that we can turn any smooth path into a smooth path that is trivial near the ends.

Lemma 36.2. Let N be a smooth manifold and let $\gamma\colon [0,1] \to N \setminus \partial N$ be a smooth path that is trivial near the ends. There exists a diffeotopy $G\colon N \times [0,1] \to N$ with compact support, rel a neighborhood of ∂N, with $G_0 = \mathrm{id}$ and with $G(P,t) = \gamma(t)$ for all $t \in [0,1]$.

Proof. Let $\gamma\colon [0,1] \to N \setminus \partial N$ be a smooth path that is trivial near the ends. Note that the map $\{0\} \times [0,1] \to N \setminus \partial N$ that is given by $(0,t) \mapsto \gamma(t)$ is a smooth isotopy that is trivial near the ends. It follows from the Isotopy Extension Theorem 36.1 that there exists a diffeotopy $G\colon N \times [0,1] \to N$ with $G_0 = \mathrm{id}$ such that for each $t \in [0,1]$ we have $G(\gamma(0),t) = \gamma(t)$. ■

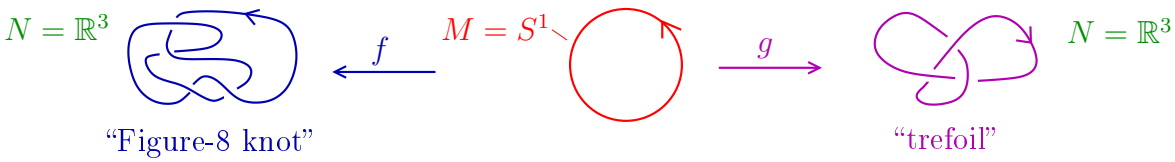
36.2. **Consequences of the Isotopy Extension Theorem 36.1.** The following corollary to the Isotopy Extension Theorem 36.1 is quite useful.

Proposition 36.3. (Smooth Isotopies-Complements Proposition) Let M be a compact smooth manifold and let N be a smooth manifold. Let $f\colon M \to N$ and $g\colon M \to N$ be two proper smooth embeddings. We suppose that there exists a proper smooth isotopy $F\colon M \times [0,1] \to N$ from f to g. Then the following two statements hold:

(1) There exists a diffeomorphism $\Phi\colon N \to N$ with $\Phi(f(M)) = g(M)$.

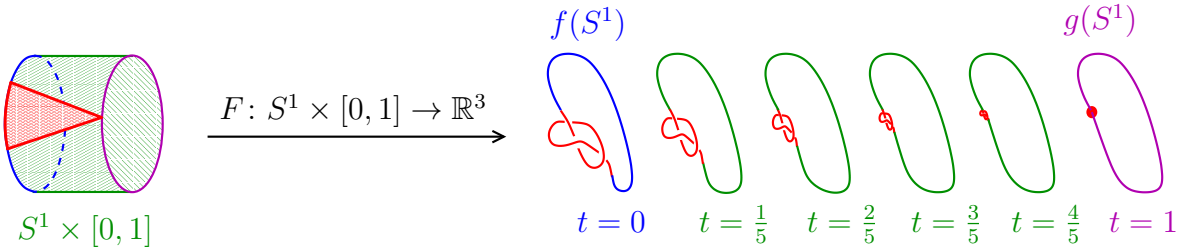
(2) There exists a diffeomorphism[359] from $N \setminus f(M)$ to $N \setminus g(M)$.

If N is oriented, then we can arrange the diffeomorphisms in (1) and (2) to be orientation-preserving.



Proof. Let M be a compact smooth manifold and let N be a smooth manifold. Let $f\colon M \to N$ and $g\colon M \to N$ be two proper smooth embeddings. Note that here proper means that $f^{-1}(\partial N) = \partial M$ and $g^{-1}(\partial N) = \partial M$. We suppose that there exists a proper smooth isotopy $F\colon M \times [0,1] \to N$ from f to g. It follows from the Trivial-Near-The-Ends-Lemma 33.4 that we can assume that F is in fact trivial near the ends.

By the Isotopy Extension Theorem 36.1, applied with $A = \partial M$ and $B = \partial N$, we know that there exists a diffeotopy $G\colon N \times [0,1] \to N$ with $G_0 = \mathrm{id}$ such that $G_1(f(M)) = g(M)$. But this implies that $G_1\colon N \to N$ is a diffeomorphism with $G_1(f(M)) = g(M)$. Evidently G_1 restricts to a diffeomorphism $N \setminus f(M) \to N \setminus g(M)$. Finally note that if N is oriented, then it follows from $G_0 = \mathrm{id}$ and the Smooth Isotopy-Orientation Proposition 34.2 that G_1 is also orientation-preserving. ■

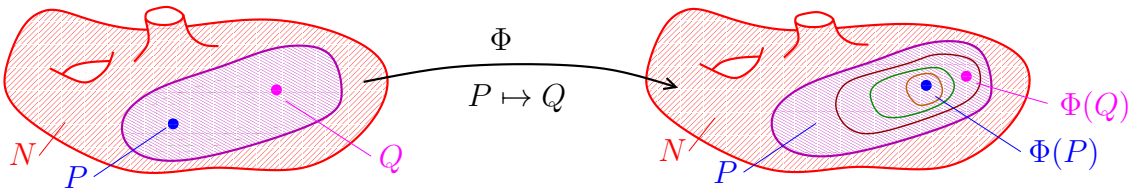


Example. A typical application of the Smooth Isotopies-Complements Proposition 36.3 is to consider smooth embeddings of S^1 into $\mathbb{R}^3$. In the figure below we see two such smooth embeddings $f, g\colon S^1 \to \mathbb{R}^3$. The question arises, whether they are smoothly isotopic or not. In Chapter 47.1 we will introduce the "fundamental group $\pi_1(X)$ of a path-connected topological X" whose isomorphism type is a homeomorphism invariant of X. In Chapter 59 we will see that the fundamental groups of the complements of $f(S^1)$ and $g(S^1)$ are not

[359] Since M is compact we know by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 that $N \setminus f(M)$ and $N \setminus g(M)$ are open subsets of N, in particular they are smooth manifolds in their own right.

isomorphic. By the Smooth Isotopies-Complements Proposition 36.3 this implies that f and g are not smoothly isotopic.

Example. The statement of the Smooth Isotopies-Complements Proposition 36.3 and the statement of the Isotopy Extension Theorem 36.1 are quite subtle. In the figure below, which is basically identical to the figure on page 813, we illustrate two smooth embeddings $f, g\colon S^1 \to \mathbb{R}^3$ and we illustrate a map $F\colon S^1 \times [0,1] \to \mathbb{R}^3$ with $F_0 = f$, $F_1 = g$ and with the property that given any $t \in [0,1]$ the corresponding map $F_t\colon S^1 \to \mathbb{R}^3$ is a smooth embedding. But similar to the previous example, we will see in Section 59.2 that the complements $\mathbb{R}^3 \setminus f(S^1)$ and $\mathbb{R}^3 \setminus g(S^1)$ are *not* diffeomorphic. This shows that in the formulations of the Smooth Isotopies-Complements Proposition 36.3 and the Isotopy Extension Theorem 36.1 it is essential that the map F is smooth on all of $M \times [0,1]$.



We conclude this section with the following refinement of the Homogeneous-via-Diffeotopies Proposition 33.14 for smooth manifolds.

Proposition 36.4. (Homogeneous-via-Diffeotopies Proposition) Let N be a connected n-dimensional smooth manifold.

(1) Given any two points P and Q in $N \setminus \partial N$ there exists a diffeotopy rel a neighborhood of ∂N from the identity to a diffeomorphism $\Phi\colon N \to N$ with $\Phi(P) = Q$.

(2) If $n \geq 2$, then given distinct points $P_1, \dots, P_m$ and distinct points $Q_1, \dots, Q_m$ in $N \setminus \partial N$ there exists a diffeotopy rel a neighborhood of ∂N from the identity to a diffeomorphism $\Phi\colon N \to N$ with $\Phi(P_i) = Q_i$ for $i = 1, \dots, m$.

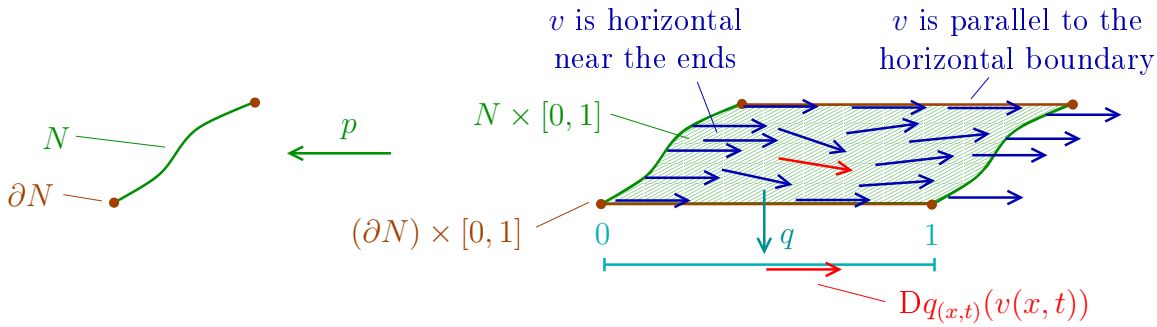
Furthermore, in both cases we can furthermore arrange that the diffeotopy has compact support.[360]

[360]Note that if N is oriented, then it follows from the Smooth Isotopy-Orientation Proposition 34.2 that in both cases Φ is in fact orientation-preserving.

Remark.

(1) In Exercise 33.8 we gave a down-to-earth proof of Proposition 36.4. In fact the down-to-earth proof also works for topological manifolds.
(2) For *non-orientable* smooth manifolds we will prove in the Orientation-Flipping Proposition 37.4 a useful addendum to Proposition 36.4.

Proof. Let N be a connected n-dimensional smooth manifold.



(1) Let P, Q be two points in $N \setminus \partial N$. By the Push Away From Boundary Lemma 18.13 we know that $N \setminus \partial N$ is also path-connected. It follows from the Smooth Path-Connectivity Proposition 19.29 that there exists a smooth path $F\colon [0,1] \to N \setminus \partial N$ from P to Q. As we saw in the proof of Lemma 36.2, a smooth path is basically the same as a smooth isotopy of a 0-dimensional manifold. By the Trivial-Near-The-Ends-Lemma 33.4 we can arrange that this smooth isotopy is trivial near the ends. The desired statement now follows from the Isotopy Extension Theorem 36.1.
(2) We prove this statement by induction on m. We dealt with the case $m = 1$ in (1). Now suppose that we know the statement for some $m \in \mathbb{N}_{\geq 2}$. Thus let $P_1, \dots, P_{m+1}$ and $Q_1, \dots, Q_{m+1}$ be two sets of distinct points in $N \setminus \partial N$. By induction we can without loss of generality already assume that $P_i = Q_i$ for $i = 1, \dots, m$.[361] Now pick disjoint closed n-balls around $P_1, \dots, P_k$ that are disjoint from $P := P_{m+1}$ and $Q := Q_{m+1}$. We denote by W the result of removing the corresponding open balls from M. By the Codimension-Zero Submanifold Proposition 19.38 we know, using the fact that $n \geq 2$, that W is a submanifold which is still connected. Thus we can apply (1) to P and Q in W to obtain a diffeotopy of W with all the desired properties. Since the diffeotopy is the identity near the boundary of W we can extend it via the identity to a diffeotopy of all of N. ∎

36.3. **Proof of the Isotopy Extension Theorem 36.1 I: Preparations.** In the following three subsection we will provide a proof of the Isotopy Extension Theorem 36.1. First we introduce some notation.

Definition. Let N be a smooth manifold. We consider the smooth manifold $N \times [0,1]$ with corner. We denote by $p\colon N \times [0,1] \to N$ and $q\colon N \times [0,1] \to [0,1]$ the two obvious projections. Let v be a vector field on[362] $N \times [0,1]$.

(1) We say v is horizontal near the ends if there exists an $\epsilon > 0$ such that for all $x \in N$ and all $t \in [0, \epsilon] \cup [1-\epsilon, 1]$ we have $v(x,t) \in \ker(\mathrm{D}p_{(x,t)}\colon \mathrm{T}_{(x,t)}(\partial N \times [0,1]) \to \mathrm{T}_x N)$.
(2) We say v is horizontally normal if for each $(x,t) \in N \times [0,1]$ we have
$$\mathrm{D}q_{(x,t)}(v(x,t)) \;=\; 1 \;\in\; \mathrm{T}_t\mathbb{R} = \widetilde{\mathrm{T}}_t\mathbb{R} = \mathbb{R}.$$
(3) We say v is parallel to the horizontal boundary if for each $(x,t) \in \partial N \times [0,1]$ we have $v(x,t) \in \mathrm{T}_{(x,t)}(\partial N \times [0,1])$.
(4) (a) Given $(x,t) \in N \times [0,1]$ we denote by $\overline{h}$ the unique vector in $\mathrm{T}_{(x,t)}(N \times [0,1])$ with $\mathrm{D}q_{(x,t)}(h) = 1$ and $\mathrm{D}p_{(x,t)}(h) = 0$.
(b) We say that v is $\overline{h}$-trivial on a set $U \subset N \times [0,1]$ if $v(x,t) = \overline{h}$ for all $(x,t) \in U$.

[361] The super vigilant reader will have noticed that implicitly we are using the Smooth Isotopy Transitivity Proposition 33.3.

The key to proving the Isotopy Extension Theorem 36.1 is the following consequence of the Flow Theorem 35.1.

Theorem 36.5. (Vector Fields-Diffeotopies Theorem) Let N be a smooth manifold. We denote by $p\colon N \times [0,1] \to N$ the projection. Suppose we are given a smooth vector field v on $N \times [0,1]$ with the following properties:

(1) The vector field is horizontal near the ends.
(2) The vector field is horizontally normal.
(3) The vector field is parallel to the horizontal boundary.
(4) The vector field is $\overline{h}$-trivial outside of a subset of the form $K \times [0,1]$ where K is a compact subset of N.

Then there exists a[363] diffeotopy $G\colon N \times [0,1] \to N$ of N with $G_0 = \mathrm{id}_N$ and with the property, that for each $(Q, t_0) \in N \times [0,1]$ we have

$$\frac{d}{dt}(t \mapsto G(Q,t))|_{t=t_0} = \quad \mathrm{D}p_{(G(Q,t_0),t_0)}(v(\underbrace{G(Q,t_0),t_0}_{\in N\times[0,1]})) \quad \in \ \mathrm{T}_{G(Q,t_0)}N.$$

Furthermore this diffeotopy is trivial near the ends and it is a diffeotopy rel $N \setminus K$.

Example. Suppose we are already given a diffeotopy $H\colon W \times [0,1] \to W$ on some compact smooth manifold W that has the properties (1)–(4) stated in the Vector Fields-Diffeotopies Theorem 36.5. We consider the vector field w on $W \times [0,1]$ that is given by

$$w(P,t_0) \ = \ \frac{d}{dt}(t \mapsto H(P,t))|_{t=t_0} \ \in \ \mathrm{T}_{(P,t_0)}(W \times [0,1]).$$

One can verify easily that this vector field satisfies the hypotheses of the Vector Fields-Diffeotopies Theorem 36.5 and that the original diffeotopy H has the properties that are promised in the Vector Fields-Diffeotopies Theorem 36.5.

The remainder of this section is dedicated to the proof of the Vector Fields-Diffeotopies Theorem 36.5. The proof consists mostly of massaging the setting till eventually one can apply the Flow Theorem 35.1. The proof does not contain any particularly interesting idea.

[362] Strictly speaking we never introduced the tangent space of a smooth manifold with corner. But literally the same definition as on page 628 also works for smooth manifolds with corner and all the obvious statements hold again. As always we strive for brevity and we will thus not develop the concept of tangent spaces of smooth manifolds with corner in detail.

[363] One can easily show, using the uniqueness statement of the Fundamental Theorem 35.7 for Autonomous ODEs, that the diffeotopy is uniquely determined by the stated properties. But we will not make use of the uniqueness statement and thus we do not claim it.

Proof. Let N be a smooth manifold. As before we denote by $p\colon N \times [0,1] \to N$ and $q\colon N \times [0,1] \to [0,1]$ the two projection s. Suppose we are given a smooth vector field v on $N \times [0,1]$ with the following properties:

(1) The vector field is horizontal near the ends.
(2) The vector field is horizontally normal.
(3) The vector field is parallel to the horizontal boundary.
(4) The vector field is $\overline{h}$-trivial outside of a subset of the form $K \times [0,1]$ where K is a compact subset of N.

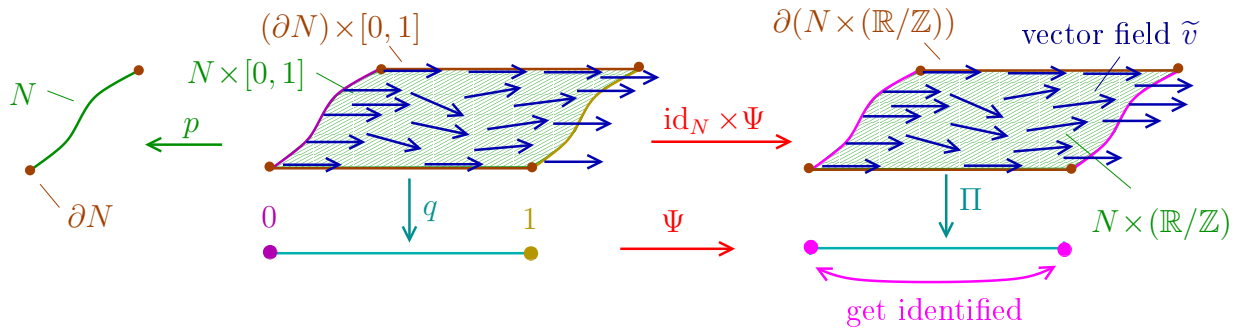
We can view v as a "time dependent" vector field on N. The Flow Theorem 35.1 does not apply to time dependent vector fields. We will get around this issue by applying the Flow Theorem 35.1 instead to the compact smooth manifold $N \times (\mathbb{R}/\mathbb{Z})$ for an appropriate vector field $\widetilde{v}$. We get a diffeotopy $\widetilde{G}\colon N \times (\mathbb{R}/\mathbb{Z}) \times [0,1] \to N \times (\mathbb{R}/\mathbb{Z})$ on $N \times (\mathbb{R}/\mathbb{Z})$ such that each corresponding time-t map is just given by addition of t in the second factor. The desired diffeotopy is then given by the map

$$G\colon N \times [0,1] \xrightarrow{(Q,s)\mapsto \widetilde{G}(Q,[0],s)} N \times (\mathbb{R}/\mathbb{Z}) \xrightarrow{\text{projection}} N.$$

We consider the compact smooth manifold $N \times (\mathbb{R}/\mathbb{Z})$ and we consider the following two smooth maps

$$\begin{array}{rcl} \Psi\colon [0,1] & \to & \mathbb{R}/\mathbb{Z} \\ t & \mapsto & [t] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \mathrm{id}_N \times \Psi\colon N \times [0,1] & \to & N \times (\mathbb{R}/\mathbb{Z}) \\ (x,t) & \mapsto & (x,[t]). \end{array}$$

Claim 1.



(1) There exists a unique smooth vector field $\widetilde{v}$ on $N \times (\mathbb{R}/\mathbb{Z})$ such that
$$\mathrm{D}(\mathrm{id}_N \times \Psi)_{(x,t)}(v(x,t)) = \widetilde{v}(x,[t]) \qquad \text{for each } (x,t) \in N \times [0,1].$$
(2) The vector field $\widetilde{v}$ on $N \times (\mathbb{R}/\mathbb{Z})$ is parallel to the boundary.

Proof.

(1) Note that it follows from our hypothesis that v is horizontal near the ends and that v is horizontally normal that there exists an $\epsilon > 0$ such that for all $x \in N$ and $t \in [0,\epsilon] \cup [1-\epsilon, 1]$ we have $v(x,t) = \overline{h}$. The promised statement follows easily from this observation. We leave it to the reader to fill in the few remaining details.
(2) It follows easily from the hypothesis that the vector field v on $N \times [0,1]$ is parallel to the horizontal boundary that the vector field $\widetilde{v}$ on $N \times (\mathbb{R}/\mathbb{Z})$ is parallel to the boundary.[364] ⊞

Claim 2. There exists a unique complete $\widetilde{v}$-flow
$$\widetilde{G}\colon N \times (\mathbb{R}/\mathbb{Z}) \times \mathbb{R} \to N \times (\mathbb{R}/\mathbb{Z}).$$

[364]Initially it might appear strange to work with $N \times (\mathbb{R}/\mathbb{Z})$. This smooth manifold has several nice properties though. It has "less boundary" than $N \times [0,1]$, so the vector field $\widetilde{v}$ is now horizontal to the boundary. We could have achieved the same result by working with $N \times \mathbb{R}$. But in our setting we will make use of the fact that $K \times (\mathbb{R}/\mathbb{Z})$ is compact, whereas $K \times \mathbb{R}$ is not compact.

Proof. As we saw in Claim 1, the vector field $\widetilde{v}$ on $N \times (\mathbb{R}/\mathbb{Z})$ is parallel to the boundary. Thus, if N is in fact compact, then the claim follows immediately from the above observation and the Flow Theorem 35.1 applied to the vector field $\widetilde{v}$ on the *compact* smooth manifold $N \times (\mathbb{R}/\mathbb{Z})$.

On the other hand, if N is non-compact, then unfortunately we cannot apply the Flow Theorem 35.1 as it is formulated, so we have to get our hands dirty a little bit. Recall that we assume that the vector field v is $\overline{h}$-trivial outside of a subset of the form $K \times [0,1]$ where K is a compact subset of N. This means that $v(x,t) = \overline{h}$ for all $(x,t) \in (N \times [0,1]) \setminus K$.

It follows from the Product Topology Properties Proposition 5.6 that $K \times (\mathbb{R}/\mathbb{Z})$ is also compact. One can easily verify that the following map defines a $\widetilde{v}$-flow:

$$\begin{array}{rcl} \widetilde{G}\colon (N \setminus K) \times (\mathbb{R}/\mathbb{Z}) \times \mathbb{R} & \to & N \times (\mathbb{R}/\mathbb{Z}) \\ ((x,[t]),s) & \mapsto & (x,[t+s]). \end{array}$$

Furthermore note that we can cover the compact set $K \times (\mathbb{R}/\mathbb{Z})$ by *finitely* many charts. It is now fairly straightforward to adapt the proof of the Flow Theorem 35.1 to give us the desired result.[365] We leave it to the reader, who is eager to show their technical prowess, to fill in the details. ⊞

Now we know that there exists a unique complete $\widetilde{v}$-flow $\widetilde{G}$. By definition of a complete $\widetilde{v}$-flow this means in particular that the following two statements hold:

(a) For each $(Q,[s]) \in N \times (\mathbb{R}/\mathbb{Z})$ we have $\widetilde{G}(Q,[s],0) = (Q,[s])$.

(b) For each $(Q,[s]) \in N \times (\mathbb{R}/\mathbb{Z})$ the map $\mathbb{R} \to N \times (\mathbb{R}/\mathbb{Z})$ given by $t \mapsto \widetilde{G}(Q,[s],t)$ is a solution of the ODE $y' = \widetilde{v}(y)$, in other words, for every $t_0 \in \mathbb{R}$ we have $\frac{d}{dt}(t \mapsto \widetilde{G}(Q,[s],t))|_{t=t_0} = \widetilde{v}(\widetilde{G}(Q,[s],t_0))$.

In the following we denote by $\Pi\colon N \times (\mathbb{R}/\mathbb{Z}) \to \mathbb{R}/\mathbb{Z}$ the obvious projection.

Claim 3. For every $(Q,[s],t) \in N \times (\mathbb{R}/\mathbb{Z}) \times \mathbb{R}$ we have $\Pi(\widetilde{G}(Q,[s],t)) = [s+t]$.

Proof. First note that we have the following commutative diagram

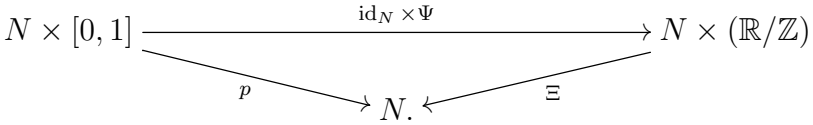
$$\begin{array}{ccc} N \times [0,1] & \xrightarrow{\mathrm{id}_N \times \Psi} & N \times (\mathbb{R}/\mathbb{Z}) \\ \downarrow{\scriptstyle q} & & \downarrow{\scriptstyle \Pi} \\ [0,1] & \xrightarrow{\Psi} & \mathbb{R}/\mathbb{Z}. \end{array}$$

[365] If $\partial N = \varnothing$, then we could apply the Compact Submanifold Exhaustion Proposition 31.2 to arrange that K is actually a compact smooth manifold.

Now let $(Q,[s],t_0) \in N \times (\mathbb{R}/\mathbb{Z}) \in \mathbb{R}$. We pick $(x,\tau) \in N \times [0,1]$ with $(x,[\tau]) = \widetilde{G}(Q,[s],t_0)$. We calculate

$$\begin{array}{lll}
\frac{d}{dt}\big(t \mapsto \Pi(\widetilde{G}(Q,[s],t))\big)\big|_{t=t_0} & \overset{\text{Chain Rule 23.10}}{=} & \mathrm{D}\Pi_{\widetilde{G}(Q,[s],t)}\big(\frac{d}{dt}(t \mapsto \widetilde{G}(Q,[s],t))\big|_{t=t_0}\big) \\
& = & (\mathrm{D}\Pi_{(x,[\tau])} \circ \mathrm{D}(\mathrm{id}_N \times \Psi)_{(x,\tau)})(v(x,\tau)) \\
& \overset{\text{by the definition of } \widetilde{v} \text{ and the choice of } (x,\tau)}{=} & \text{the image of } 1 \in \mathrm{T}_\tau\mathbb{R} \text{ in } \mathrm{T}_{[\tau]}(\mathbb{R}/\mathbb{Z}). \\
& \overset{\text{since } v \text{ is horizontally normal}}{=} &
\end{array}$$

$$\begin{array}{lll}
\overset{\text{by the above Statement (b) and the definition of } \tau}{=} & \mathrm{D}\Pi_{(x,[\tau])}(\widetilde{v}(\widetilde{G}(Q,[s],t_0))) \\
= & (\mathrm{D}\Psi_\tau \circ \mathrm{D}q_{(x,\tau)})(v(x,\tau)) \\
\overset{\text{by the above commutative diagram together with the Chain Rule 23.10}}{=} &
\end{array}$$



The claim follows almost immediately from this calculation and some elementary arguments from real analysis. ⊞

Finally we denote by $\Xi\colon N \times (\mathbb{R}/\mathbb{Z}) \to N$ the natural projection and we consider the map

$$G\colon N \times [0,1] \xrightarrow{(Q,s)\mapsto \widetilde{G}(Q,[0],s)} N \times (\mathbb{R}/\mathbb{Z}) \xrightarrow{\Xi} N.$$

Claim 4. The map $G\colon N \times [0,1] \to N$ has the desired properties.

Proof. First note that it follows from (a) that $G_0 = \mathrm{id}_N$. Next note that it follows easily from Claim 3 together with the Submanifold Smooth Structure Lemma 19.24 (3) that G is a diffeotopy. Next we want to show that the derivatives of $t \mapsto G(Q,t)$ are of the promised form. Note that we have the following simple minded commutative diagram:

Now let $(Q,t_0) \in N \times [0,1]$. By Claim 3 we know that $\widetilde{G}(Q,[0],t_0)$ is of the form $\widetilde{G}(Q,[0],t_0) = (x,[t_0])$ for some $x \in N$. We calculate

$$\begin{array}{lll}
\frac{d}{dt}(t \mapsto G(Q,t))|_{t=t_0} & \overset{\text{definition of } G}{=} & \frac{d}{dt}(t \mapsto \Xi(\widetilde{G}(Q,[0],t)))|_{t=t_0} \\
& = & \mathrm{D}\Xi_{(x,[t_0])}(\widetilde{v}(x,[t_0])) \\
& \overset{\text{by (b)}}{=} & \mathrm{D}p_{(x,t_0)}(v(x,t_0)) \\
& \overset{\text{by the above commutative diagram}}{=} &
\end{array}$$

$$\begin{array}{lll}
\overset{\text{Chain Rule 23.10}}{=} & \mathrm{D}\Xi_{(x,[t_0])}\big(\frac{d}{dt}(t \mapsto \widetilde{G}(Q,[0],t))\big|_{t=t_0}\big) \\
= & (\mathrm{D}\Xi_{(x,[t_0])} \circ \mathrm{D}(\mathrm{id}_N \times \Psi))(v(x,t_0)) \\
\overset{\text{by definition of } \widetilde{v}}{=} & \mathrm{D}p_{(G(x,t_0),t_0)}(v(G(x,t_0),t_0)). \\
\overset{\text{by the definition of } G \text{ and } x}{=} &
\end{array}$$

We conclude the proof of the claim with two observations:

(1) It follows from this calculation, the uniqueness statement of the Fundamental Theorem 35.7 for Autonomous ODEs and the fact that the vector field v is horizontal near the ends, that the diffeotopy $G\colon N \times [0,1] \to N$ is trivial near the ends.
(2) Recall that we assume that there exists a compact subset $K \subset N$ such that the vector field v is $\overline{h}$-trivial outside of $K \times [0,1]$. It follows from the above calculation and the uniqueness statement of the Fundamental Theorem 35.7 for Autonomous ODEs that the diffeotopy $G\colon N \times [0,1] \to N$ is a diffeotopy rel $N \setminus K$. ■

36.4. Proof of the Isotopy Extension Theorem 36.1 II: Closed smooth manifolds.

We now turn to the actual proof of the Isotopy Extension Theorem 36.1. In this section we will prove the theorem if M and N are closed. This setting makes the discussion much easier and the key idea of the proof becomes clearer. The general case will be proved in the subsequent section.

Evidently, in the setting of the Isotopy Extension Theorem 36.1, we want to use the Vector Fields-Diffeotopies Theorem 36.5 to construct the desired diffeotopy. Thus we need to construct suitable vector fields. We will do so locally and patch them together. This leads us to the following variation on the above definitions from page 865.

Definition. Let N be a smooth manifold. Let $U \subset N \times [0,1]$ be a subset and let v be a vector field on U. We denote by $p\colon N \times [0,1] \to N$ and $q\colon N \times [0,1] \to [0,1]$ the two obvious projections.

(1) We say v is horizontal near the ends if there exists an $\epsilon > 0$ such that for all $(x,t) \in U$ with $t \in [0,\epsilon] \cup [1-\epsilon, 1]$ we have $v(x,t) \in \ker(\mathrm{D}p_{(x,t)}\colon \mathrm{T}_{(x,t)}(\partial N \times [0,1]) \to \mathrm{T}_x N)$.

(2) We say v is horizontally normal if for each $(x,t) \in U$ we have

$$\mathrm{D}q_{(x,t)}(v(x,t)) \;=\; 1 \;\in\; \mathrm{T}_t\mathbb{R} \;=\; \widetilde{\mathrm{T}}_t\mathbb{R} \;=\; \mathbb{R}.$$

The following lemma is the key to patching together promising vector fields.

Lemma 36.6. Let N be a smooth manifold, let $U \subset N \times [0,1]$ be an open subset, let v_1, v_2 be two vector fields on U and let $f_1, f_2\colon U \to \mathbb{R}$ be two smooth maps.

(1) If v_1 and v_2 are horizontal near the ends, then so is $f_1 \cdot v_2 + f_2 \cdot v_2$.

(2) If $f_1 + f_2 \equiv 1$ and if v_1 and v_2 are horizontally normal, then so is $f_1 \cdot v_2 + f_2 \cdot v_2$.

Proof. We start out with the proof of Statement (1). We assume that the vector fields v_1 and v_2 are horizontal near the ends. With the hopefully obvious notation we pick suitable $\epsilon_1 > 0$ and $\epsilon_2 > 0$ and we set $\epsilon := \min\{\epsilon_1, \epsilon_2\}$. Now let $(x,t) \in U$ with $t \in [0,\epsilon] \cup [1-\epsilon, 1]$. We see that

$$\mathrm{D}p_{(x,t)}(f_1(x,t)\cdot v_2(x,t) + f_2(x,t)\cdot v_2(x,t)) \overset{\text{since differentials are linear}}{\downarrow} = f_1(x,t)\cdot\underbrace{\mathrm{D}p_{(x,t)}(v_1(x,t))}_{=0} + f_2(x,t)\cdot\underbrace{\mathrm{D}p_{(x,t)}(v_2(x,t))}_{=0}.$$

Next we turn to the proof of Statement (2). Now we assume that $f_1 + f_2 \equiv 1$. We see that

$$\begin{aligned}\mathrm{D}q_{(x,t)}(f_1(x,t)\cdot v_2(x,t) + f_2(x,t)\cdot v_2(x,t)) &= f_1(x,t)\cdot\underbrace{\mathrm{D}q_{(x,t)}(v_1(x,t))}_{=1} + f_2(x,t)\cdot\underbrace{\mathrm{D}q_{(x,t)}(v_2(x,t))}_{=1} \\ &= f_1(x,t) + f_2(x,t) \;=\; 1.\end{aligned}$$

■

Now we turn to the proof of the Isotopy Extension Theorem 36.1 in the special case that M and N are both closed smooth manifolds.

Proof of the Isotopy Extension Theorem 36.1 if M and N are closed smooth manifolds. Let M be a closed m-dimensional smooth manifold and let N be a closed n-dimensional smooth manifold. Let $F\colon M \times [0,1] \to N$ be a smooth isotopy which is trivial near the ends. We need to show that there exists a diffeotopy $G\colon N \times [0,1] \to N$ with the following properties:

(1) $G_0 = \mathrm{id}$.

(2) We have $G \circ (F_0 \times \mathrm{id}) = F\colon M \times [0,1] \to N$, in other words, we have

$$G(F_0(x),t) \;=\; F(x,t) \qquad \text{for all } x \in M \text{ and } t \in [0,1].$$

(3) G is trivial near the ends.

The idea is to construct the diffeotopy using the Vector Fields-Diffeotopies Theorem 36.5. We introduce the following notation:

(1) Since $F\colon M \times [0,1] \to N$ is a smooth isotopy it follows as in the fairly straightforward Exercise 33.10 that

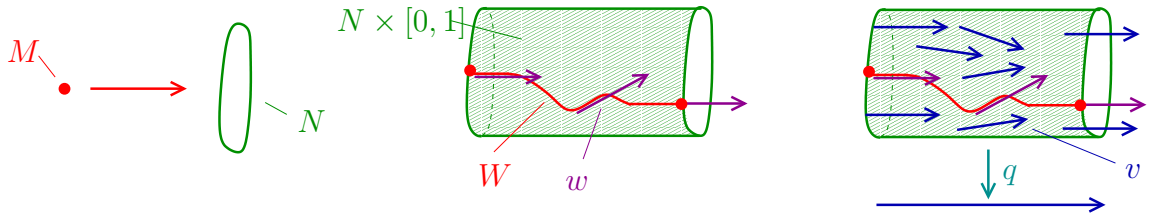
$$\begin{array}{rcl} \widetilde{F}\colon M \times [0,1] & \to & N \times [0,1] \\ (P,t) & \mapsto & (F(P,t),t) \end{array}$$

is a proper smooth embedding. In particular we obtain from the Smooth Embedding Theorem 24.10 that $W := \widetilde{F}(M \times [0,1])$ is a proper submanifold of $N \times [0,1]$ such that for any $(P,t) \in M \times (0,1)$ the point $Q = \widetilde{F}(P,t)$ admits a submanifold chart of type (α).

(2) We denote by $p\colon N \times [0,1] \to N$ and $q\colon N \times [0,1] \to [0,1]$ the two projection s.

(3) Basically as on page 866 we consider the vector field w on W that for $(F(P,t),t) \in W \subset N \times [0,1]$ is uniquely determined by

$$\begin{array}{rcl} \mathrm{D}p_{(F(P,t),t)}(w(F(P,t),t)) & = & \frac{d}{ds}\big(s \mapsto F(P,s)\big)|_{s=t} \;\in\; \mathrm{T}_{F(P,t)}N \\ \mathrm{D}q_{(F(P,t),t)}(w(F(P,t),t)) & = & 1 \;\in\; \mathrm{T}_t\mathbb{R} = \mathbb{R}. \end{array}$$



One can easily verify that w is horizontal near the ends and horizontally normal.

Claim 1. There exists a smooth vector field v on $N \times [0,1]$ with the following properties:

(1) The vector field v is horizontal near the ends.

(2) The vector field v is horizontally normal.

(3) On $W \cap (N \times [0,1])$ the vector field v agrees with w.

Proof.

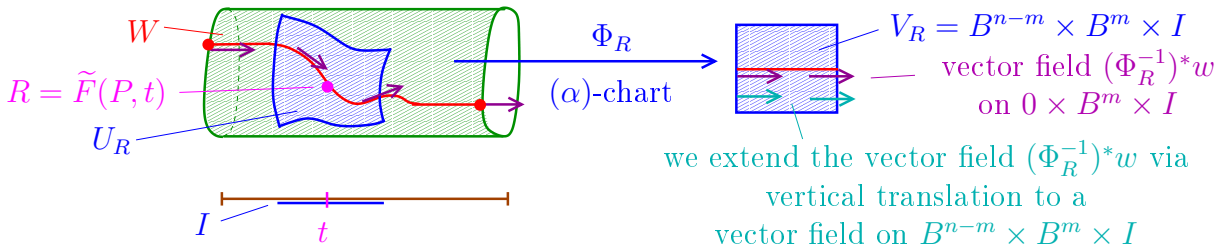
The idea is to construct such a vector field v by constructing suitable vector fields on open subsets of $N \times [0,1]$ which form an open cover of $N \times [0,1]$. We paste these vector fields together using a partition of unity and using Lemma 36.6.

Since the smooth isotopy $F\colon M \times [0,1] \to N$ is by hypothesis trivial near the ends there exists an $\epsilon > 0$ such that $F(P,t) = F(P,0)$ for all $t \in [0,\epsilon]$ all $P \in N$ and such that $F(P,t) = F(P,1)$ for all $t \in [1-\epsilon,1]$ and all $P \in N$. On the open subset $U_0 := N \times [0,1] \setminus \widetilde{F}(M \times [\epsilon,1-\epsilon])$ we define the vector field v_0 to be given by the vector $\overline{h}$ at each point.

Now let $R = \widetilde{F}(P,t)$ with $P \in M$ and $t \in (\epsilon,1-\epsilon)$. As we mentioned above, the point $R = \widetilde{F}(P,t) \in W \subset N \times [0,1]$ admits a submanifold chart of type (α). In fact, similar to the Smooth Embedding Theorem 24.10 one can show that there exists even an

open neighborhood I of $t \in (0,1)$, an open neighborhood U_R of $R \in N \times [0,1]$ and a chart $\Phi_R \colon U_R \to V_R = B^{n-m} \times B^m \times I$ with the following properties:

- $\Phi_R(U_R \cap W) = \{0\} \times B^m \times I$,
- the map $U_R \xrightarrow{\Phi_R} B^{n-m} \times B^m \times I \xrightarrow{(x,y,t) \mapsto t} I$ equals q.



We now use Φ_R to extend w on $U_R \cap W$ to a vector field v_R on U_R as follows:

(x) We consider the vector field $(\Phi_R^{-1})^* w$ on $\Phi_R(U_R \cap W) = \{0\} \times B^m \times I$.
(y) We extend the vector field from (x) to a vector field on $B^{n-m} \times B^m \times I$ by "vertical translation".
(z) We use Φ_R to transport the vector field from (y) back to U_R.

One can can easily verify that the vector field u_0 and that the vector fields u_R are horizontal near the ends, that they are horizontally normal and that they agree with w on W.

Next note that by the Manifold-Partitions of Unity Existence Theorem 21.1 we can find a smooth partition of unity $f_0 \colon N \times [0,1] \to \mathbb{R}$ and $\{f_R \colon N \times [0,1] \to \mathbb{R}\}_{R \in \widetilde{F}(M \times (\epsilon, 1-\epsilon))}$ such that $\operatorname{supp}(f_0) \subset U_0$ and such that we always have $\operatorname{supp}(f_R) \subset U_R$. We denote by $\widetilde{f_0 \cdot v_0}$ the extension of the vector field $f_0 \cdot v_0$ on U_0 to all of $N \times [0,1]$ by setting it zero outside of U_0. The same way we define $\widetilde{f_R \cdot v_R}$. The vector field v is now given by the sum of $\widetilde{f_0 \cdot v_0}$ and of all the vector fields $\widetilde{f_R \cdot v_R}$.

It now follows from a very mild generalization of Lemma 36.6 that v does indeed have all the desired properties. ⊞

We now take the smooth vector field v on $N \times [0,1]$ from Claim 1 and we plug it into the Vector Fields-Diffeotopies Theorem 36.5. We obtain a diffeotopy $G \colon N \times [0,1] \to N$ with $G_0 = \mathrm{id}$ and such that for each $(Q,t) \in N \times [0,1]$ we have

$$\frac{d}{ds}(s \mapsto G(P,s))|_{s=t} \;=\; \mathrm{D}p_{(G(P,t),t)}(v(\underbrace{G(P,t),t}_{\in N \times [0,1]})) \;\in\; \mathrm{T}_{G(Q,t)}N.$$

Furthermore we saw in the Vector Fields-Diffeotopies Theorem 36.5 that G is trivial near the ends. Thus it remains to prove the following claim.

Claim 2. For each $x \in M$ and $t \in [0,1]$ we have $G(F_0(x),t) = F(x,t)$.

Proof. Let $x \in M$. We have $G(F_0(x),0) = F_0(x) = F(x,0)$. Furthermore, as we had just seen, for each $t \in [0,1]$ we have

$$\frac{d}{ds}\big(s \mapsto G(F_0(x),s)\big)\big|_{s=t} \;\underset{\text{see above}}{=}\; \mathrm{D}p_{(G(F_0(x),s),s)}(v(G(F_0(x),t),t).$$

Next note that we have

$$\frac{d}{ds}(s \mapsto F(x,s))|_{s=t} \underset{\substack{\uparrow \\ \text{definition of } w, \text{ see page 871}}}{=} \mathrm{D}p_{(F(x,t),t)}(w(F(x,t),t)) \underset{\substack{\uparrow \\ \text{since } w = v \text{ on } W}}{=} \mathrm{D}p_{(F(x,t),t)}(v(F(x,t),t)).$$

It follows from these observations that the maps

$$\begin{array}{rcl} [0,1] & \to & M \times [0,1] \\ t & \mapsto & (G(F_0(x),t),t) \end{array} \quad \text{and} \quad \begin{array}{rcl} [0,1] & \to & M \times [0,1] \\ t & \mapsto & (F(x,t),t) \end{array}$$

are both solutions of the ODE $(y,t)' = (\mathrm{D}p_{(y,t)}(v(y,t)),1)$ on $N \times [0,1]$ and both satisfy the same starting condition. Using charts one can apply the uniqueness statement of the Fundamental Theorem 35.7 for Autonomous ODEs and we see that for all $t \in [0,1]$ we have $G(F_0(x),t) = F(x,t)$. ■

36.5. **Proof of the Isotopy Extension Theorem 36.1 III: The general case.** In this section we finally provide the proof of the Isotopy Extension Theorem 36.1 in its fullest generality. The basic idea is identical to the idea of the proof in the special case considered in the previous section. But the presence of boundary and the fact that we allow N to be non-compact makes everything technically much more demanding and, let's face it, much less readable.

Definition. Let N be a smooth manifold. Let $U \subset N \times [0,1]$ be a subset and let v be a vector field on U.

(3) We say v is parallel to the horizontal boundary if for each $(x,t) \in (\partial N \times [0,1]) \cap U$ we have $v(x,t) \in \mathrm{T}_{(x,t)}(\partial N \times [0,1])$.

We will need the following addendum to Lemma 36.6.

Lemma 36.6. Let N be a smooth manifold, let $U \subset N \times [0,1]$ be an open subset, let v_1, v_2 be two vector fields on U and let $f_1, f_2 \colon U \to \mathbb{R}$ be two smooth maps.

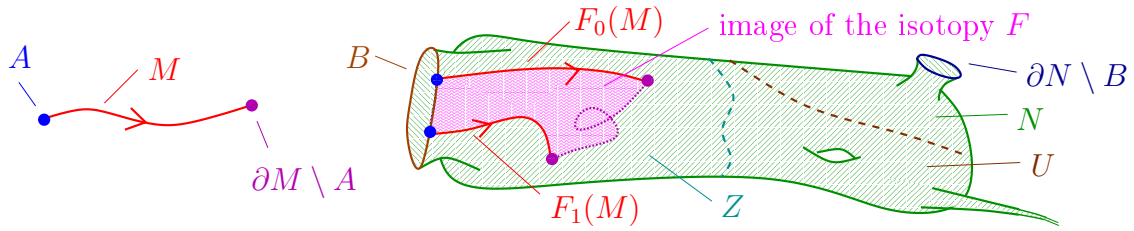
(3) If v_1 and v_2 are parallel to the horizontal boundary, then so is $f_1 \cdot v_2 + f_2 \cdot v_2$.

Proof. If v_1 and v_2 are two vector fields that are parallel to the horizontal boundary, then for any $(x,t) \in (\partial N \times [0,1]) \cap U$ we have

$$\mathrm{D}p_{(x,t)}(f_1(x,t)\cdot v_2(x,t) + f_2(x,t)\cdot v_2(x,t)) = f_1(x,t)\cdot \underbrace{\mathrm{D}p_{(x,t)}(v_1(x,t))}_{\in \mathrm{T}_{(x,t)}(\partial N \times [0,1])} + f_2(x,t)\cdot \underbrace{\mathrm{D}p_{(x,t)}(v_2(x,t))}_{\in \mathrm{T}_{(x,t)}(\partial N \times [0,1])}.$$

Now we are done, since $\mathrm{T}_{(x,t)}(\partial N \times [0,1])$ is a vector subspace. ■

Proof of the Isotopy Extension Theorem 36.1. Let M be a compact n-dimensional smooth manifold and let N be an m-dimensional smooth manifold. Furthermore let A be a union of components of ∂M and let B be a union of components of ∂N. Finally let $F \colon M \times [0,1] \to N$ be a smooth isotopy which is trivial near the ends and which has the following property:



$(*)$ For each $t \in [0,1]$ we have $F_t(A) \subset B$ and we have $F_t(\partial M \setminus A) \subset N \setminus \partial N$.

Finally suppose that we are given an open subset U of N with $F(M \times [0,1]) \subset U$.

Claim 0. There exists an open subset Z of N with the following three properties:

(1) $F(M \times [0,1]) \subset Z \subset U$,

(2) $N \setminus Z$ is a neighborhood of $\partial N \setminus B$,
(3) the closure $\overline{Z}$ is compact.

Proof. By the Smooth Manifold Boundary Proposition 19.26 we know that $\partial N \setminus B$ is a closed subset of N. Furthermore since M is compact we obtain from the Compact-Closed Lemma 1.21, the Product Topology Properties Proposition 5.6 and the Compact Image Lemma 2.13 that $F(M \times [0,1])$ is a closed subset of N. Note that by hypothesis $F(M \times [0,1])$ and $\partial N \setminus B$ are disjoint. By the Manifold Paracompact-Normal Proposition 18.9 (2) we know that N is normal in the sense of the definition on page 123. Thus there exist open disjoint subsets S and T of N with $F(M \times [0,1]) \subset S$ and $\partial N \setminus B \subset T$.

The subset $U \cap S$ satisfies (1) and (2), but not necessarily (3). Thus we apply the Compact Exhaustion Lemma 9.3 (1) (2) to the topological space $U \cap S$, which is second-countable, Hausdorff and regionally compact, and the compact subspace $F(M \times [0,1])$, and we obtain a subset $Z \subset U \cap S$ with all the desired properties. ⊞

It remains to show that there exists a diffeotopy $G\colon N \times [0,1] \to N$ with the following properties:

(1) $G_0 = \mathrm{id}$.
(2) We have $G \circ (F_0 \times \mathrm{id}) = F\colon M \times [0,1] \to N$, in other words, we have

$$G(F_0(x), t) \;=\; F(x,t) \quad \text{for all } x \in M \text{ and } t \in [0,1].$$

(3) G is trivial near the ends.
(4) G is a diffeotopy rel $N \setminus Z$.[366]

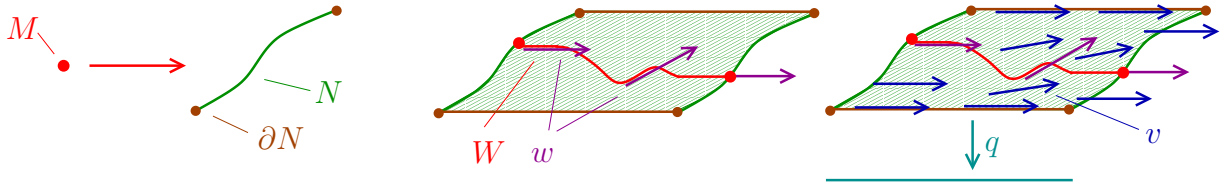
Again the idea is to construct the diffeotopy using the Vector Fields-Diffeotopies Theorem 36.5. We introduce the following notation:[367]

(1) We extend the smooth isotopy $F\colon M \times [0,1] \to N \times [0,1]$ to a map $F\colon M \times \mathbb{R} \to N \times \mathbb{R}$ by setting $F(P,t) = F(P,0)$ for $t \le 0$ and $F(P,t) = F(P,1)$ for $t \ge 1$. Since F is a smooth isotopy that is trivial near the ends we obtain from the Smooth Pasting Proposition 19.23 that F is again smooth.
(2) Since F is a smooth isotopy it follows, as in the fairly elementary Exercise 33.10, that

$$\begin{array}{rcl} \widetilde{F}\colon M \times \mathbb{R} & \to & N \times \mathbb{R} \\ (P,t) & \mapsto & (F(P,t),t) \end{array}$$

[366] Since $G_0 = \mathrm{id}$, since G is a diffeotopy rel $N \setminus Z$ and since $\overline{Z}$ is compact we see that G is a diffeotopy with compact support.
[367] In the following we partially work with $N \times \mathbb{R}$ which has the big advantage that this is a smooth manifold with boundary $\partial N \times \mathbb{R}$, whereas $N \times [0,1]$ is a smooth manifold with corner $\partial N \times \{0,1\}$, for which we have fewer ready-made results. For example we never developed the concept of a submanifold of a smooth manifold with corner.

is a smooth embedding such that $\widetilde{F}(M\times\mathbb{R})$ is a closed subset of $N\times\mathbb{R}$. In particular we obtain from the Smooth Embedding Theorem 24.10 and the proof thereof that $W := \widetilde{F}(M\times\mathbb{R})$ is a proper submanifold of $N\times\mathbb{R}$ such that for any $(P,t)\in M\times\mathbb{R}$ the following three statements hold:
(a) If $P\in M\setminus\partial M$, then $Q=\widetilde{F}(P,t)$ admits a submanifold chart of type (α).
(b) If $P\in A$, then $Q=\widetilde{F}(P,t)$ admits a submanifold chart of type (β).
(c) If $P\in\partial M\setminus A$, then $Q=\widetilde{F}(P,t)$ admits a submanifold chart of type (γ).



(3) We denote by $p\colon N\times[0,1]\to N$ and $q\colon N\times[0,1]\to[0,1]$ the two projection s.

(4) Basically as on page 866 we consider the vector field w on $W\cap(N\times[0,1])$ that for $(F(P,t),t)\in W\subset N\times[0,1]$ is uniquely determined by

$$\begin{aligned}\mathrm{D}p_{(F(P,t),t)}(w(F(P,t),t)) &= \tfrac{d}{ds}\big(s\mapsto F(P,s)\big)|_{s=t} \in \mathrm{T}_{F(P,t)}N\\ \mathrm{D}q_{(F(P,t),t)}(w(F(P,t),t)) &= 1 \in \mathrm{T}_t\mathbb{R}=\mathbb{R}.\end{aligned}$$

One can easily verify that w is horizontal near the ends, parallel to the horizontal boundary and horizontally normal.

Claim 1. There exists a smooth vector field v on $N\times[0,1]$ with the following properties:
(1) The vector field v is horizontal near the ends.
(2) The vector field v is horizontally normal.
(3) The vector field v is parallel to the horizontal boundary.
(4) The vector field v is $\overline{h}$-trivial outside of the compact set $\overline{Z}$.
(5) On $W\cap(N\times[0,1])$ the vector field v agrees with w.

Proof.

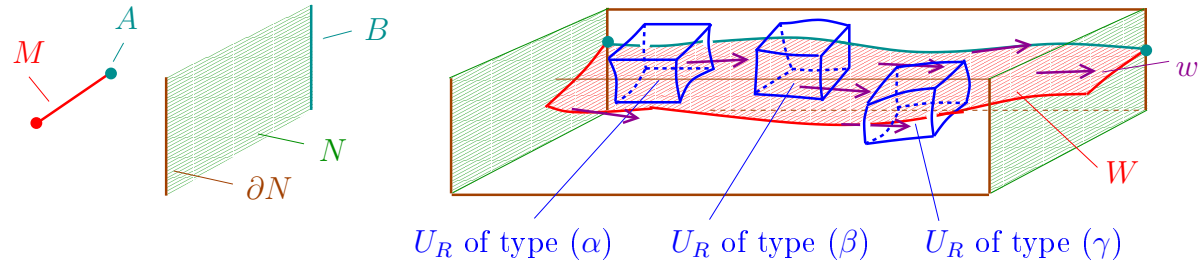
The idea is again to construct such a vector field v by constructing suitable vector fields around each point in $N\times[0,1]$ and by pasting them together using a partition of unity and using Lemma 36.6.

Thus let $R\in N\times[0,1]$.

(α) Suppose that $R=\widetilde{F}(P,t)$ with $P\in M\setminus\partial M$ and $t\in[0,1]$. As we mentioned above, the point $R=\widetilde{F}(P,t)\subset W\subset N\times\mathbb{R}$ admits a submanifold chart of type (α). In fact, similar to the Smooth Embedding Theorem 24.10 one can show that there exists even an open neighborhood I of $t\in\mathbb{R}$, an open neighborhood U_R of $R\in N\times[0,1]$, with $U_R\subset(N\setminus\partial N)\times[0,1]$ and with $U_R\subset Z\times[0,1]$, and a chart $\Phi_R\colon U_R\to V_R=B^{n-m}\times B^m\times I$ with the following properties:
- $\Phi_R(U_R\cap W)=\{0\}\times B^m\times I$,
- the map $U_R\xrightarrow{\Phi_R}B^{n-m}\times B^m\times I\xrightarrow{(x,y,t)\mapsto t}I$ equals q,
- $U_R\cap U=\varnothing$.

We now use Φ_R to extend w on $U_R \cap W$ to a vector field v_R on U_R as follows:
(x) The combination of Φ_R and w defines a vector field on $\Phi_R(U_R \cap W) = \{0\} \times B^m \times I$.
(y) We extend the vector field from (x) to a vector field on $B^{n-m} \times B^m \times I$ by "vertical translation".
(z) We use Φ_R to transport the vector field from (y) back to U_R.

(β) Suppose that $R = \widetilde{F}(P,t)$ with $P \in A$ and $t \in [0,1]$. We pick a submanifold chart $\Phi_R \colon U_R \to V_R = B^{n-m} \times B^m \times I$ of type (β) around R with $U_R \subset Z \times [0,1]$ and we define a vector field v_R on U_R in a similar fashion to (α).



(γ) Suppose that $R = \widetilde{F}(P,t)$ with $P \in \partial M \setminus A$ and $t \in [0,1]$. We pick a submanifold chart $\Phi_R \colon U_R \to V_R = B^{n-m} \times B^m \times I$ of type (γ) around R with $U_R \subset Z \times [0,1]$. We need to modify the battle plan from (α).
(x) Since in our current setting we have a submanifold chart of type (γ) we have $\Phi_R(U_R \cap W) = \{0\} \times B^m_{\geq 0} \times I$. Therefore the combination of Φ_R and w now defines a smooth vector field on $\Phi_R(U_R \cap W) = \{0\} \times B^m_{\geq 0} \times I$.
(x̂) Using the Whitney Extension Theorem 19.6 we can extend the smooth vector field on $\{0\} \times B^m_{\geq 0}$ to a smooth vector field on $\{0\} \times B^m \times I$.
Now we perform (y) and (z) as above.

(δ) If $R \notin W = \widetilde{F}(M \times [0,1])$, then we set $U_R = (N \times [0,1]) \setminus W$ and we denote by v_R the unique $\overline{h}$-trivial vector field on U_R.

Note that one can easily verify that each of these four types of vector fields is horizontal near the ends, parallel to the horizontal boundary and horizontally normal on its domain.

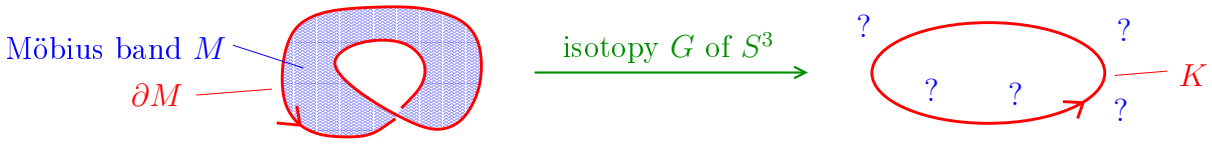
By the Manifold-Partitions of Unity Existence Theorem 21.1 we can find a partition of unity $\{f_R \colon N \times [0,1] \to \mathbb{R}\}_{R \in N \times [0,1]}$ such that for each $R \in N \times [0,1]$ we have $\operatorname{supp}(f_R) \subset U_R$. For each $R \in N \times [0,1]$ we denote by $\widetilde{f_R \cdot v_R}$ the extension of the vector field $f_R \cdot v_R$ on $U_R \cap (N \times [0,1])$ to all of $N \times [0,1]$ by setting it zero outside of U_R. The vector field v is now given by the sum over all the vector fields $\widetilde{f_R \cdot v_R}$.

It follows from a very mild generalization of Lemma 36.6 that v does indeed have all the desired properties. ⊞

We now take the smooth vector field v on $N \times [0,1]$ from Claim 1 and we plug it into the Vector Fields-Diffeotopies Theorem 36.5. We obtain a diffeotopy $G \colon N \times [0,1] \to N$ with $G_0 = \mathrm{id}$ and such that for each $(Q,t) \in N \times [0,1]$ we have

$$\frac{d}{ds}(s \mapsto G(P,s))|_{s=t} \;=\; \mathrm{D}p_{(G(P,t),t)}(v(\underbrace{G(P,t),t}_{\in N \times [0,1]})) \;\in\; \mathrm{T}_{G(Q,t)}N.$$

Furthermore we saw in the Vector Fields-Diffeotopies Theorem 36.5 that G is trivial near the ends and that it is a diffeotopy rel $N \setminus Z$. In particular it is a diffeotopy rel $N \setminus U$, rel some neighborhood of $\partial N \setminus B$ and it has compact support.



It remains to prove the following claim.

Claim 2. For each $x \in M$ and $t \in [0,1]$ we have $G(F_0(x), t) = F(x,t)$.

Proof. Fortunately we had proved this claim on page 872. ∎

Exercises for Chapter 36.

Exercise 36.1. We consider the Möbius band M in $\mathbb{R}^3$ as shown in the figure below. It should be pretty clear that there exists an isotopy F which turns ∂M into the unknot K. By the Isotopy Extension Theorem 36.1 this isotopy F can be extended to a diffeotopy G of $\mathbb{R}^3$. In particular we obtain a map $G_1 \colon \mathbb{R}^3 \to \mathbb{R}^3$ with $G_1(\partial M) = K$. What does $G_1(M)$ look like? Put differently, we just saw that there exists an embedded Möbius band in $\mathbb{R}^3$ with boundary given by K. What does it look like?

Exercise 36.2.

(a) Give an example of a connected smooth manifold M with empty boundary such that for every $P \in M$ the two smooth manifolds $M \setminus \{P\}$ and M are diffeomorphic.
(b) Give an example of a connected smooth manifold M with non-empty boundary such that for every $P \in M$ the two smooth manifolds $M \setminus \{P\}$ and M are diffeomorphic.

Exercise 36.3. Let $n \in \mathbb{N}_{\geq 2}$.

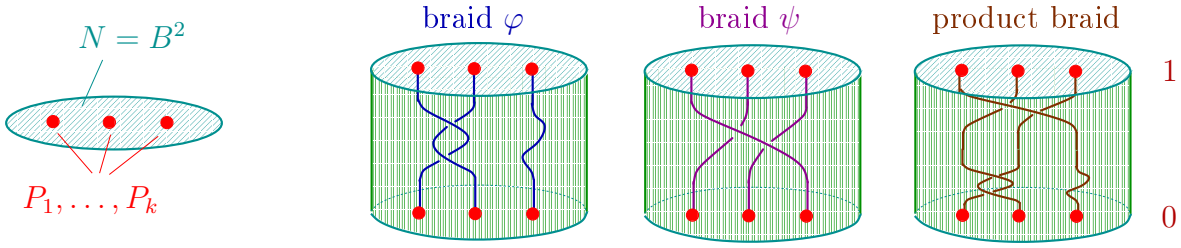
(a) Let $P \subset \mathbb{R}^n$ be a finite set. Show that there exists a smooth embedding $f \colon S^{n-1} \to \mathbb{R}^n$ with $P \subset f(S^{n-1})$.
(b) Show that the conclusion of (a) in general does not hold if P is a countable bounded subset of $\mathbb{R}^n$.

Exercise 36.4. Let M be a connected 2-dimensional smooth manifold without boundary. Furthermore let $P_1, \dots, P_k \in M$ be disjoint points. We denote by $\pi \colon M \times [0,1] \to [0,1]$ the natural projection. A *braid in* M is a smooth embedding $\varphi \colon \bigsqcup_{i=1}^{k} \{i\} \times [0,1] \to M \times [0,1]$ such that the following four conditions are satisfied:

(1) We have $\varphi(\{1,\dots,k\} \times \{0\}) = \{P_1, \dots, P_k\}$ and $\varphi(\{1,\dots,k\} \times \{1\}) = \{P_1, \dots, P_k\}$.
(2) There exists an $\epsilon > 0$ such that $\varphi(i,t) = \varphi(i,0)$ for $i = 1, \dots, k$ and every $t \in [0, \epsilon]$.
(3) There exists an $\epsilon > 0$ such that $\varphi(i,t) = \varphi(i,1)$ for $i = 1, \dots, k$ and every $t \in [1-\epsilon, 1]$.
(4) For each $i \in \{1, \dots, k\}$ and $t \in [0,1]$ we have $\pi(\varphi(i,t)) = t$.

We say that two braids φ_0, φ_1 as above are *equivalent* if there exists a smooth map $\Phi\colon \bigsqcup_{i=1}^{k} \{i\} \times [0,1] \times [0,1] \to M \times [0,1]$ such that $\Phi_0 = \varphi_0$, $\Phi_1 = \varphi_1$ and such that each Φ_t is a braid. We denote by $B_k(M) := B_k^{P_1,\dots,P_k}(M)$ the set of equivalence classes of braids.

(1) Show that the map

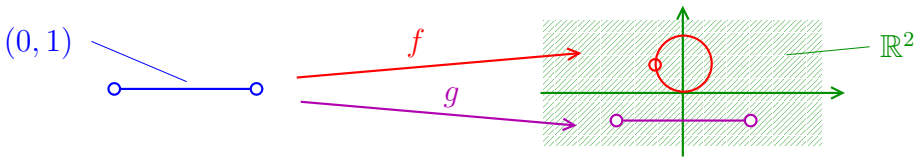


$$\begin{array}{rcl} B_k(M) \times B_k(M) & \to & B_k(M) \\ ([\varphi],[\psi]) & \mapsto & \left[\begin{array}{rcl} \{1,\dots,k\} \times [0,1] & \to & M \\ (i,t) & \mapsto & \begin{cases} \varphi(i,2t), & \text{if } t \in [0,\frac{1}{2}], \\ \psi(i,2t-1), & \text{if } t \in [\frac{1}{2},1] \end{cases} \end{array} \right] \end{array}$$

defines a group structure on $B_k(M)$.

(2) Show that the isomorphism type of $B_k(M)$ does not depend on the choice of the distinct points $P_1, \dots, P_k$.

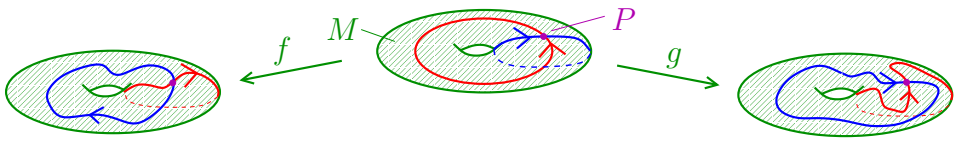
(3) Why do we only consider 2-dimensional smooth manifolds?



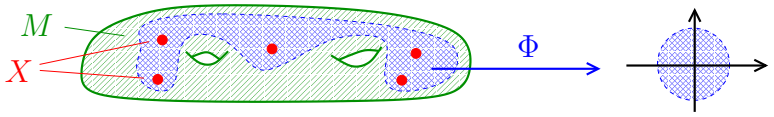
Remark. The group $B_k(M)$ is called the *k-braid group of M*. The group $B_k := B_k(B^2)$ is commonly called *the k-braid group*.

Exercise 36.5. We consider the two smooth embeddings

$$f\colon \begin{array}{rcl} (-1,1) & \to & \mathbb{R}^2 = \mathbb{C} \\ t & \mapsto & \exp(\pi i t) + \mathrm{i} \end{array} \qquad \text{and} \qquad g\colon \begin{array}{rcl} (-1,1) & \to & \mathbb{R}^2 \\ t & \mapsto & (2t,-1) \end{array}$$



that are shown in the figure below. Show that f and g are smoothly isotopic and show that there is no diffeotopy $G\colon \mathbb{R}^2 \times [0,1] \to \mathbb{R}^2$ with $G_0 = \mathrm{id}$ and $G_1 \circ f = g$.



Exercise 36.6. Let $n \in \mathbb{N}$ and let $\varphi, \psi\colon \overline{B}^n \to S^n$ be smooth embeddings with disjoint images. Show that $S^n \setminus (\varphi(B^n) \cup \psi(B^n))$ is diffeomorphic to $S^{n-1} \times [0,1]$.

Exercise 36.7. Let M be a connected orientable smooth manifold and let $f\colon M \to M$ be an orientation-preserving diffeomorphism that fixes a point $P \in M \setminus \partial M$. Show that there exists a diffeotopy rel $\{P\}$ from f to a diffeomorphism $g\colon M \to M$ that is the identity on an open neighborhood of P.

Exercise 36.8. Let M be a connected smooth manifold.

(a) Let $X \subset M \setminus \partial M$ be a finite set. Show that there exists a chart $\Phi\colon U \to B^n$ of type (i) such that $X \subset U$.
(b) We now suppose that ∂M is non-empty and connected. Let $X \subset M \setminus \partial M$ be a finite set. Show that there exists a chart $\Phi\colon U \to B^n_{\geq 0}$ of type (ii) such that $X \subset U$.

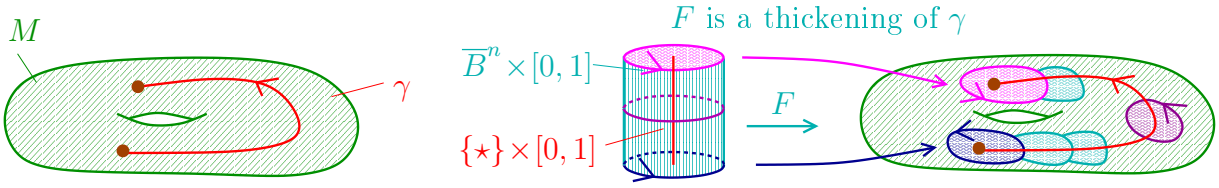
Exercise 36.9. We consider the proper smooth embedding $f\colon \mathbb{R} \to \mathbb{R}^3$ that is shown in the figure below and we consider the standard smooth embedding $g\colon \mathbb{R} \to \mathbb{R}^3$ that is given by $x \mapsto (x, 0, 0)$. Show that there exists a *proper* smooth isotopy $F\colon \mathbb{R} \times [0,1] \to \mathbb{R}^3$ with $F_0 = f$ and $F_1 = g$.
Remark. Recall that according to the definition on page 812 a map $F\colon \mathbb{R} \times [0,1] \to \mathbb{R}^3$ is a proper smooth isotopy if each F_t is a proper smooth embedding and if $F\colon \mathbb{R} \times [0,1] \to \mathbb{R}^3$ is proper, i.e. if the preimage of each compact subspace of $\mathbb{R}^3$ is a compact subspace of $\mathbb{R} \times [0,1]$. *Remark.* In Chapter 59 we will study the "fundamental groups" of the complements of $\mathbb{R}^3 \setminus f(\mathbb{R})$ and $\mathbb{R}^3 \setminus g(\mathbb{R})$ and we will see that they are not isomorphic. As in the Smooth Isotopies-Complements Proposition 36.3 this shows that there is no homeomorphism $\Phi\colon \mathbb{R}^3 \to \mathbb{R}^3$ with $\Phi \circ f = g$. In particular there is no diffeotopy $G\colon \mathbb{R}^3 \times [0,1] \to \mathbb{R}^3$ with $G(f(x), t) = F(x, t)$ for all $(x, t) \in \mathbb{R} \times [0,1]$. This shows again that in the formulation of the Isotopy Extension Theorem 36.1 it is difficult to replace the hypothesis that M is compact by a weaker condition.

37. Orientation-preserving and orientation-reversing loops

In this chapter we will apply the Isotopy Extension Theorem 36.1 to introduce and study the concept of orientation-preserving and orientation-reversing loops. We will use this concept and various results from earlier chapters to classify smooth embeddings of balls into smooth manifolds.

37.1. Orientation-preserving reversing and orientation-reversing loops.

Definition. Let X be a topological space and let $\gamma\colon [0,1] \to X$ be a path.



(1) We say γ is a loop if $\gamma(0) = \gamma(1)$.

(2) We say γ is trivial near the ends if there exists an $\epsilon > 0$ such that for each $t \in [0, \epsilon]$ we have $\gamma(t) = \gamma(0)$ and if for each $t \in [1-\epsilon, 1]$ we have $\gamma(t) = \gamma(1)$.[368]

Let M be an n-dimensional smooth manifold and let $\gamma\colon [0,1] \to M \setminus \partial M$ be a smooth path.

(3) Throughout this section we denote the origin of $\overline{B}^n$ by $\star$.

(4) A thickening of the smooth path γ is a smooth isotopy $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ such that for each $t \in [0,1]$ we have $F(\star, t) = \gamma(t)$.

Proposition 37.1. (Path-Thickening Proposition) Let M be a smooth manifold and let $\gamma\colon [0,1] \to M \setminus \partial M$ be a smooth path that is trivial near the ends.

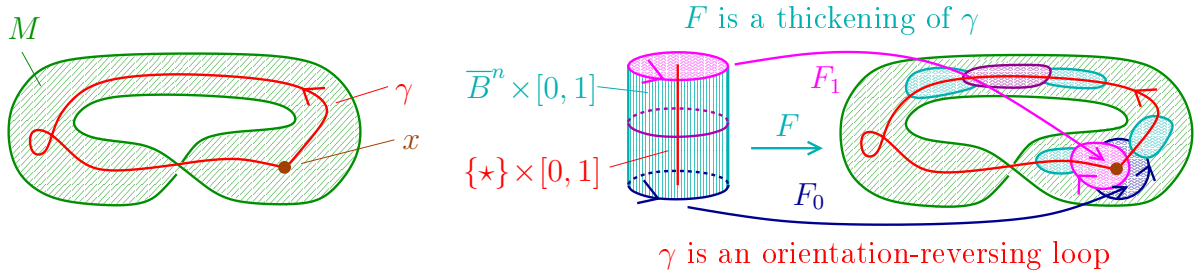
(1) Given any smooth embedding $\varphi\colon \overline{B}^n \to M \setminus \partial M$ with $\varphi(\star) = \gamma(0)$ there exists a thickening $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ that is trivial near the ends with $F_0 = \varphi$.

(2) Given any smooth embedding $\psi\colon \overline{B}^n \to M \setminus \partial M$ with $\psi(\star) = \gamma(1)$ there exists a thickening $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ that is trivial near the ends with $F_1 = \psi$.

Proof. Let M be an n-dimensional smooth manifold and let $\gamma\colon [0,1] \to M \setminus \partial M$ be a smooth path that is trivial near the ends. We provide the proof of Statement (1). The proof of Statement (2) is very similar.

As in the proof of Lemma 36.2 we point out that the map $\{\star\} \times [0,1] \to M \setminus \partial M$ that is given by $(\star, t) \mapsto \gamma(t)$ is a smooth isotopy that is trivial near the ends. It follows from the Isotopy Extension Theorem 36.1 that there exists a diffeotopy $F\colon M \times [0,1] \to M$ that is trivial near the ends with $F_0 = \mathrm{id}$ and such that for each $t \in [0,1]$ we have $F(\star, t) = \gamma(t)$. Let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ be a smooth embedding with $\varphi(\star) = \gamma(0)$. The map

$$\begin{array}{rcl} F \circ (\varphi \times \mathrm{id}_{[0,1]})\colon \overline{B}^n & \to & M \\ (x,t) & \mapsto & F(\varphi(x), t) \end{array}$$



is a thickening of γ that is trivial near the ends with $F_0 = \varphi$. ∎

[368] As so often it follows from the Trivial-Near-The-Ends-Lemma 33.4 that we can turn any smooth path into a smooth path that is trivial near the ends.

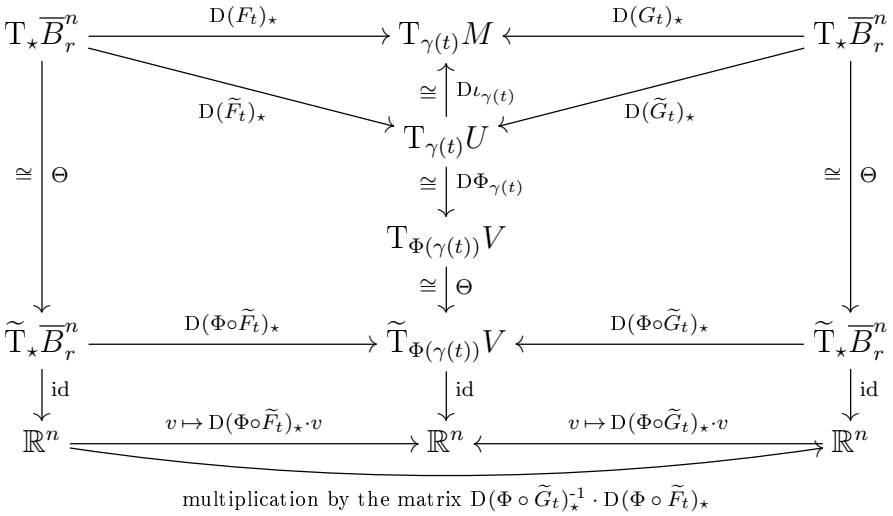
Definition. Let M be an n-dimensional smooth manifold and let $\gamma\colon [0,1] \to M \setminus \partial M$ be a loop that is trivial near the ends. By the Path-Thickening Proposition 37.1 we can pick a thickening $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ of γ. We say γ is orientation-preserving if the automorphism

$$\mathrm{T}_\star \overline{B}^n \xrightarrow[\cong]{\mathrm{D}(F_0)_\star} \mathrm{T}_{\gamma(0)} M \xleftarrow[\cong]{\mathrm{D}(F_1)_\star} \mathrm{T}_\star \overline{B}^n$$

of the vector space $\mathrm{T}_\star \overline{B}^n$ is orientation-preserving. Otherwise we say that γ is orientation-reversing.

Remark. On page 1114 we will give an alternative and slightly more general definition of orientation-preserving and orientation-reversing loops. In Proposition 49.10 we will see that the two definitions are equivalent for smooth paths that take values in $M \setminus \partial M$.

Proposition 37.2. Let M be a smooth manifold. The above definition of a loop being orientation-preserving does not depend on the choice of the thickening.



Proof. Let M be an n-dimensional smooth manifold and let $\gamma\colon [0,1] \to M \setminus \partial M$ be a loop that is trivial near the ends. Let $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ and $G\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ be two thickenings of γ.

Claim. The map
$$\begin{array}{rcl} [0,1] & \to & \mathbb{R} \setminus \{0\} \\ t & \mapsto & \det\left((\mathrm{D}(G_t)_\star)^{-1} \circ \mathrm{D}(F_t)_\star \colon \mathrm{T}_\star \overline{B}^n \to \mathrm{T}_{\gamma(t)} M \to \mathrm{T}_\star \overline{B}^n \right) \end{array}$$
is continuous. In particular, either all values are positive or all values are negative.

Proof. We need to show that the given map is continuous. By the Pasting Proposition 2.6 it suffices to show that the given map is locally continuous.

Let $t \in [0,1]$. We pick a chart $\Phi\colon U \to V$ around $\gamma(t)$. We denote by $\iota\colon U \to M$ the inclusion map. Since $F, G\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ are in particular continuous and since U is open there exists an open neighborhood I of $t \in [0,1]$ and an $r > 0$ such that $F(\overline{B}^n_r \times I) \subset U$ and such that $G(\overline{B}^n_r \times I) \subset U$. We denote by $\widetilde{F}_t\colon \overline{B}^n \to U$ and $\widetilde{G}_t\colon \overline{B}^n \to U$

the unique maps with $F_t = \iota \circ \widetilde{F}_t$ and with $G_t = \iota \circ \widetilde{G}_t$. We consider the following diagram

We make the following clarifications and observations:

(1) The maps Θ are the natural isomorphisms provided by the Tangent Space-Isomorphism Proposition 23.16.
(2) The pentagons commutes since the maps Θ are natural.
(3) The triangles commute by the functoriality of differentials.
(4) By the Differential-equals-Differential Lemma 23.4 the differential of a smooth map between the physical tangent spaces of open subsets of $\mathbb{R}^n$ is just given by multiplication by the $(n \times n)$-matrix that is given by the various partial derivatives. In other words, the two bottom squares commute.

It follows from the above discussion and the fact that F and G are "smooth in t", that the map of the claim is continuous on I. We have thus shown that the given map is locally continuous which, as we mentioned above, implies by the Pasting Proposition 2.6, that the given map is continuous. ⊞

Finally we consider the following little commutative diagram:

$$\begin{array}{ccc} \mathrm{T}_\star \overline{B}^n & \xrightarrow[\cong]{(\mathrm{D}(F_1)_\star)^{-1} \circ \mathrm{D}(F_0)_\star} & \mathrm{T}_\star \overline{B}^n \\ {\scriptstyle (\mathrm{D}(G_0)_\star)^{-1} \circ \mathrm{D}(F_0)_\star} \downarrow \cong & & \cong \downarrow {\scriptstyle (\mathrm{D}(G_1)_\star)^{-1} \circ \mathrm{D}(F_1)_\star} \\ \mathrm{T}_\star \overline{B}^n & \xrightarrow[\cong]{(\mathrm{D}(G_1)_\star)^{-1} \circ \mathrm{D}(G_0)_\star} & \mathrm{T}_\star \overline{B}^n \end{array}$$

It follows from the claim that the vertical isomorphism to the left is orientation-preserving if and only if the vertical isomorphic to the right is orientation-preserving. It follows from this observation and the Orientation-Composition Lemma 25.3 that the top horizontal map is orientation-preserving if and only if the bottom horizontal map is orientation-preserving. We have thus shown that it does not matter whether we work with the thickening F or the thickening G. ■

Proposition 37.3. (Orientability-via-Loops Proposition) Let M be a connected smooth manifold and let $P \in M \setminus \partial M$. The following four statements are equivalent:

(1) M is orientable,
(2) $M \setminus \partial M$ is orientable,
(3) every loop $\gamma\colon [0,1] \to M \setminus \partial M$ that is trivial near the ends is orientation-preserving,
(4) every loop $\gamma\colon [0,1] \to M \setminus \partial M$ with $\gamma(0) = \gamma(1) = P$ that is trivial near the ends is orientation-preserving.

Proof. Let M be a connected n-dimensional smooth manifold and let $P \in M \setminus \partial M$. The implication (1) $\Rightarrow$ (2) is basically obvious. The implication (2) $\Rightarrow$ (1) is the content of the Complement-of-Boundary Orientation Lemma 25.16.

We turn to the proof of the implication (2) $\Rightarrow$ (3). Thus we now assume that we can pick an orientation for $M \setminus \partial M$. Let $\gamma\colon [0,1] \to M \setminus \partial M$ be a loop that is trivial near the ends. We need to show that γ is orientation-preserving. We pick a thickening $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ of γ. By the Smooth Isotopy-Orientation Proposition 34.2 we know that each $\mathrm{D}F_t\colon \mathrm{T}_\star \overline{B}^n \to \mathrm{T}_{\gamma(t)} M$ is orientation-preserving or each such map is orientation-reversing. In particular the map is orientation-preserving for $t = 0$ if and only if it is for $t = 1$. It follows immediately that the loop γ is orientation-preserving.

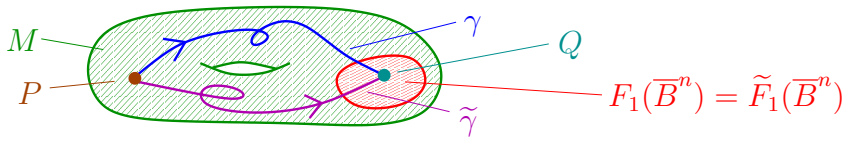
The implication (3) $\Rightarrow$ (4) is a tautology. Therefore at this stage it remains to prove the implication (4) $\Rightarrow$ (2). This proof will require the remainder of this proof.

Thus, in the following we assume that every smooth smooth path $\gamma\colon [0,1] \to M \setminus \partial M$ with $\gamma(0) = \gamma(1) = P$ that is trivial near the ends is orientation-preserving. We need to show that $M \setminus \partial M$ is orientable.

We pick an orientation $\mathcal{O}_P$ of $\mathrm{T}_P M$. Let $Q \in M \setminus \partial M$. By the Push Away From Boundary Lemma 18.13 we know that $M \setminus \partial M$ is also path-connected. It follows from the Smooth Path-Connectivity Proposition 19.29 together with the Trivial-Near-The-Ends-Lemma 33.4 that there exists a smooth path $\gamma\colon [0,1] \to M \setminus \partial M$ from P to Q that is trivial near the ends. By the Path-Thickening Proposition 37.1 there exists a thickening $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ of γ that is trivial near the ends. We equip $\mathrm{T}_Q M$ with the orientation $\mathcal{O}_Q$ that is given by the image of the orientation $\mathcal{O}_P$ of $\mathrm{T}_P M$ under the isomorphism

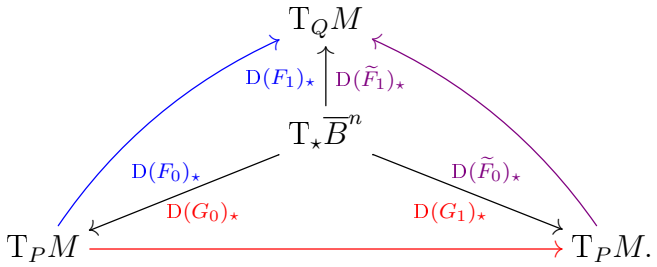
$$\mathrm{T}_P M \xrightarrow{(\mathrm{D}(F_0)_\star)^{-1}} \mathrm{T}_\star \overline{B}^n \xrightarrow{\mathrm{D}(F_1)_\star} \mathrm{T}_Q M.$$

Claim 1. This orientation of $\mathrm{T}_Q M$ does not depend on the choice of the smooth path γ.



Proof. Let $\widetilde{\gamma}\colon [0,1] \to M \setminus \partial M$ be another smooth path from P to Q that is trivial near the ends. Recall that by the Path-Thickening Proposition 37.1 (2) there exists a thickening $\widetilde{F}\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ of $\widetilde{\gamma}$ that is trivial near the ends *and* which has the property that $\widetilde{F}_1\colon \overline{B}^n \to M \setminus \partial M$ equals $F_1\colon \overline{B}^n \to M \setminus \partial M$. We consider the concatenations

$$\delta\colon [0,1] \to M \setminus \partial M, \quad t \mapsto \begin{cases} \gamma(2t), & \text{if } t \in [0, \frac{1}{2}], \\ \widetilde{\gamma}(2-2t), & \text{if } t \in [\frac{1}{2}, 1] \end{cases} \quad \text{and}$$



$$G\colon \overline{B}^n \times [0,1] \to M \setminus \partial M, \quad (x,t) \mapsto \begin{cases} F(x, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ \widetilde{F}(x, 2-2t), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}$$

It follows from the fact that $F_1 = \widetilde{F}_1$ that the maps are well-defined and it follows from the fact that γ, $\widetilde{\gamma}$, F and $\widetilde{F}$ are trivial near the ends, together with the Smooth Pasting

Proposition 19.23, that δ and G are actually smooth. Evidently δ is a loop and G is a thickening of δ.

Finally we consider the following diagram:

We make the following clarifications and observations:

(1) By construction we have $F_1 = \widetilde{F}_1$ and we have $G_0 = F_0$, $G_1 = \widetilde{F}_0$. Thus the two maps on the arrows are always the same map.
(2) The undecorated colored maps are defined to be the composition of the (inverse) of the two maps of the same color. In other words, the diagram commutes by definition.
(3) By hypothesis δ is orientation-preserving. This means that the horizontal red map at the bottom is orientation-preserving.
(4) It follows from the above that the blue map induces the same orientation on $\mathrm{T}_Q M$ as the violet map. ⊞

At this state it suffices to prove the following claim.

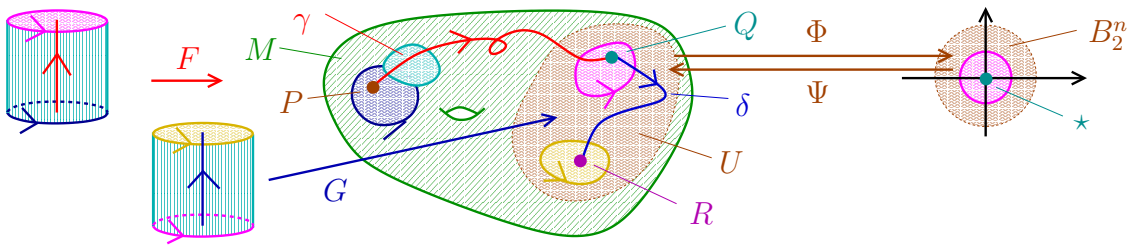
Claim 2. The orientations of the tangent spaces $\mathrm{T}_Q M$ define an orientation on $M \setminus \partial M$.

Proof. We will use the criterion from the Orientations-via-Atlas Lemma 25.8 to verify that these orientations define an orientation on $M \setminus \partial M$. Thus let $Q \in M \setminus \partial M$.

Before we do anything else we introduce the following little notation: for each $x \in B_2^n$ we denote by $\mathcal{S}_x \in \mathrm{T}_x \overline{B}^n$ the standard orientation.

Next we pick a chart $\Phi\colon U \to B_2^n$ around Q with $\Phi(Q) = \star$ and which has the property that the map $\mathrm{D}\Phi_Q\colon \mathrm{T}_Q U \to \mathrm{T}_\star \overline{B}_2^n$ sends the orientation $\mathcal{O}_Q$ to the standard orientation $\mathcal{S}_\star$ of $\mathrm{T}_\star \overline{B}_2^n$. As usual we denote the inverse of the chart Φ by $\Psi\colon B_2^n \to U$. By the Orientations-via-Atlas Lemma 25.8 it now suffices to show that Φ is orientation-preserving for every $R \in U$. Put differently, we need to show that for each $R \in U$ we have $\mathrm{D}\Phi_R(\mathcal{O}_R) = \mathcal{S}_{\Phi(R)}$.

We pick a smooth path $\gamma\colon [0,1] \to M \setminus \partial M$ from P to Q that is trivial near the ends. It follows from the Path-Thickening Proposition 37.1 (2) that we can pick a thickening $F\colon \overline{B}^n \times [0,1] \to M \setminus \partial M$ of γ that is trivial near the ends and which has the property that $F_1\colon \overline{B}^n \to M$ equals $\Psi\colon \overline{B}^n \to U \subset M$.



Given $R \in U$ we pick a path $\delta\colon [0,1] \to U$ from Q to R that is trivial near the ends. We use the Path-Thickening Proposition 37.1 (2) to find a thickening $G\colon \overline{B}^n \times [0,1] \to U$

of δ with $G_0 = F_1$. Note that

we use the path γ and the thickening F to define the orientation $\mathcal{O}_Q$, and
we use the path and the thickening that are given by concatenating γ and δ and F and G
to define the orientation $\mathcal{O}_R$,
equality then follows easily from the chain rule

$$\begin{array}{ccccc} \mathrm{D}\Phi_R(\mathcal{O}_R) & \overset{\downarrow}{=} & \mathrm{D}\Phi_R((\mathrm{D}(G_1)_\star \circ \mathrm{D}(G_0)_\star^{-1})(\mathcal{O}_Q)) & = & \mathrm{D}\Phi_R((\mathrm{D}(G_1)_\star \circ \mathrm{D}(G_0)_\star^{-1})((\mathrm{D}\Phi_\star^{-1})(\mathcal{S}_\star))) \\ & = & (\mathrm{D}(\Phi \circ G_1)_\star \circ (\mathrm{D}(\Phi \circ G_0)_\star)^{-1})(\mathcal{S}_\star) & = & \mathcal{S}_{\Phi(R)}. \\ & \overset{\uparrow}{} & & \overset{\uparrow}{} & \end{array}$$

chain rule — since $G_0 \circ \Phi$ and $G_1 \circ \Phi$ are smoothly isotopic maps from $\overline{B}^n \to B_2^n$ we obtain the equality from the Smooth Isotopy-Orientation Proposition 34.2 ■

Remark. In Section 49.4 we will give an alternative and slightly more general definition of orientation-preserving and orientation-reversing loops. In Proposition 49.10 we will see that the two definitions are equivalent for smooth paths that take values in $M \setminus \partial M$. In fact in Section 49.4 we will study orientation-preserving and reversing loops in greater detail. For example we will see that if two loops are homotopic, then one is orientation-preserving if and only if the other is. In principle one could try to prove this statement with the techniques of the current section, but that promises to be a technical mess.

37.2. Orientation flipping diffeotopies I.

Proposition 37.4. (Orientation-Flipping Proposition) Let M be a *non-orientable* connected smooth manifold and let $X, Y \subset M \setminus \partial M$ be two disjoint finite subsets. There exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:

(1) $F_0 = \mathrm{id}$.
(2) F has compact support.
(3) F is a diffeotopy rel $\partial M \cup Y$.
(4) $\Phi := F_1$ is the identity on $X \cup Y$.
(5) The map $\Phi := F_1$ has the following properties:
  (a) For each $x \in X$ the map $\mathrm{D}\Phi_x\colon \mathrm{T}_x M \to \mathrm{T}_x M$ is orientation-reversing.
  (b) For each $y \in Y$ the map $\mathrm{D}\Phi_y\colon \mathrm{T}_y M \to \mathrm{T}_y M$ is orientation-preserving.

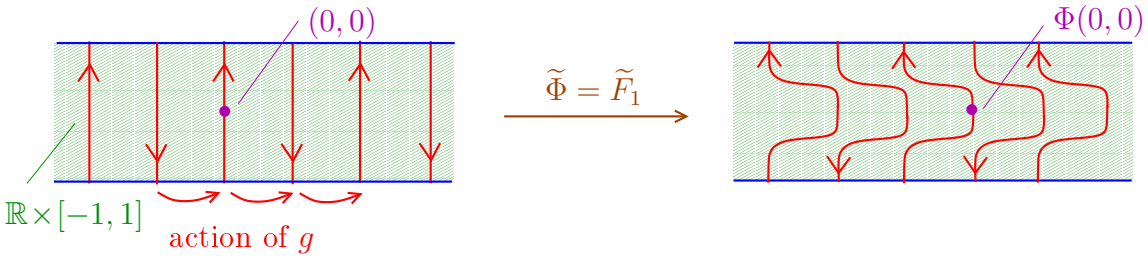
Remark.

(1) It follows from the Smooth Isotopy-Orientation Proposition 34.2 that the conclusion of this proposition does *not* hold for *orientable* smooth manifolds.
(2) In Section 49.5 we will give a somewhat different proof of the Orientation-Flipping Proposition 37.4.

Example. We consider $\widetilde{M} := \mathbb{R} \times [-1,1]$ and the orientation-reversing self-diffeomorphism

$$\begin{array}{rccc} g\colon \widetilde{M} = \mathbb{R} \times [-1,1] & \to & \widetilde{M} = \mathbb{R} \times [-1,1] \\ (r,s) & \mapsto & (r+1,-s). \end{array}$$

Recall that the Möbius band is defined as $M = \widetilde{M}/\sim$ where $P \sim g(P)$. We denote by $p\colon \mathbb{R} \times [-1,1] \to M$ the projection. Let $x = p(0,0)$. We want to find a diffeotopy $F\colon M \times [0,1] \to M$ as in the Orientation-Flipping Proposition 37.4, with $X = \{x\}$ and $Y = \varnothing$. Using the Smooth Transition Function Lemma 19.4 we can find a smooth map $\tau\colon [-1,1] \to [0,1]$ such that $\tau(0) = 1$, such that $\tau(t) = 0$ for $s \geq \frac{1}{2}$ and such that $\tau(-s) = \tau(s)$ for all $s \in [-1,1]$. We consider the map



$$\begin{array}{rcl} \widetilde{F}\colon \widetilde{M} \times [0,1] & \to & \widetilde{M} \\ ((r,s),t) & \mapsto & ((r + t \cdot \tau(s), s) \end{array}$$

that is sketched in the figure below. Note that $\widetilde{F}$ descends to a map $F\colon M \times [0,1] \to M$ which is a diffeotopy rel ∂M with $F_0 = \mathrm{id}$ and with $F_1(x) = x$. We set $\widetilde{\Phi} := \widetilde{F}_1$ and $\Phi := F_1$. We claim that $\mathrm{D}\Phi_x\colon \mathrm{T}_x M \to \mathrm{T}_x M$ is orientation-reversing. To show this statement let us consider the following diagram

$$\begin{array}{ccccc} \mathrm{T}_{(0,0)}(\mathbb{R}\times[-1,1]) & \xrightarrow{\mathrm{D}\widetilde{\Phi}_{(0,0)}} & \mathrm{T}_{(1,0)}(\mathbb{R}\times[-1,1]) & \xrightarrow{\mathrm{D}(g^{-1})_{(1,0)}} & \mathrm{T}_{(0,0)}(\mathbb{R}\times[-1,1]) \\ \downarrow{\scriptstyle \mathrm{D}p_{(0,0)}} & & & \searrow^{\mathrm{D}p_{(1,0)}} & \downarrow{\scriptstyle \mathrm{D}p_{(0,0)}} \\ \mathrm{T}_{p(0,0)}M & & \xrightarrow{\quad\mathrm{D}\Phi_{p(0,0)}\quad} & & \mathrm{T}_{p(0,0)}M. \end{array}$$

Note that $p \circ \widetilde{\Phi} = \Phi \circ p$ and $p \circ g = p$. Thus the diagram commutes by the functoriality of the differential.

Since $F_0 = \mathrm{id}$ we know by the Smooth Isotopy-Orientation Proposition 34.2 that $F_1 = \Phi$ is also orientation-preserving. In particular $\mathrm{D}\widetilde{\Phi}_{(0,0)}$ is orientation-preserving. On the other hand $\mathrm{D}(g^{-1})_{(1,0)} = (\mathrm{D}g_{(0,0)})^{-1}$ is orientation-reversing. In summary we see that the composition of the top horizontal maps is an orientation-reversing automorphism of $\mathrm{T}_{(0,0)}(\mathbb{R} \times [-1,1])$. The left and right vertical maps are honest-to-G*d the same isomorphism. Therefore it follows from the elementary Lemma 25.7 that the bottom horizontal map is also orientation-reversing.[369]

For the proof of the Orientation-Flipping Proposition 37.4 we will need the following two little lemmas.

Auxiliary Lemma 37.5. Let X be a topological manifold, let $A \subset X$ be a closed subset and let $F\colon X \times [0,1] \to X$ be a homotopy rel A. If F has compact support, then there exists an open neighborhood U of A such that F is a homotopy rel U.

Proof of Lemma 37.5. Let $K \subset X$ be a compact subset such that $F(x,t) = x$ for all $x \notin K$ and all $t \in [0,1]$. Since X is in particular Hausdorff we know by the Compact-Closed

[369] Note that this example gives a solution to Exercise 25.17.

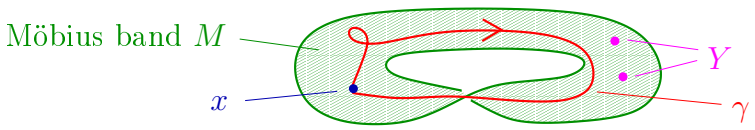
Lemma 1.21 (2) that K is a closed subset of X. Since X is a topological manifold we know by the Manifold Paracompact-Normal Proposition 18.9 (2) that X is normal. This implies in particular that there exists an open neighborhood U of A that is disjoint from K. But then F is evidently a homotopy rel U. ■

Auxiliary Lemma 37.6. Let M be a smooth manifold and let U be an open subset of M. Furthermore let $G\colon U \times [0,1] \to U$ be a diffeotopy with compact support K. Then

$$\begin{array}{rcl} \widetilde{G}\colon M \times [0,1] & \to & M \\ (x,t) & \mapsto & \begin{cases} G(x,t), & \text{if } x \in K, \\ x, & \text{if } x \notin K \end{cases} \end{array}$$

is a diffeotopy of M.

Proof. Since K is a compact subset of U we know by the Compact Image Lemma 2.13 and the Product Topology Properties Proposition 5.6 that $K \times [0,1]$ is a compact, and hence a closed subset of $M \times [0,1]$. Thus we see that $\widetilde{G}$ is smooth on the open subsets $U \times [0,1]$ and $M \times [0,1] \setminus K \times [0,1]$. Since these open subsets cover $M \times [0,1]$ it follows from the Smooth Pasting Proposition 19.23, or to be precise its extension to smooth manifolds with corner, that $\widetilde{G}$ is smooth. Basically the same argument shows that each $\widetilde{G}_t$ is a diffeomorphism. ■



All the work for the proof of the Orientation-Flipping Proposition 37.4 is now done in the proof of the following auxiliary lemma, which deals with the case that $\#X = 1$.

Auxiliary Lemma 37.7. Let M be a connected *non-orientable* smooth manifold. Furthermore let $Y \subset M$ be a finite set and let $x \in M \setminus \partial M$ be a point with $x \notin Y$. There exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:

(1) $F_0 = \mathrm{id}$.
(2) F has compact support.
(3) F is a diffeotopy rel $\partial M \cup Y$.
(4) $\Phi := F_1$ is the identity on $\{x\} \cup Y$.
(5) The map $\Phi := F_1$ has the following properties:
  (a) The map $\mathrm{D}\Phi_x\colon \mathrm{T}_x M \to \mathrm{T}_x M$ is orientation-reversing.
  (b) For each $y \in Y$ the map $\mathrm{D}\Phi_y\colon \mathrm{T}_y M \to \mathrm{T}_y M$ is orientation-preserving.

Proof of Lemma 37.7. Let M be a connected *non-orientable* smooth manifold. Note that by the Smooth 1-Dimensional Manifold Classification Theorem 22.7 we know that $\dim(M) \geq 2$. Let $Y \subset M$ be a finite set and let $x \in M \setminus \partial M$ with $x \notin Y$.

(a) We pick an orientation $\mathcal{O}_x$ for $\mathrm{T}_x M$.
(b) We set $W := M \setminus Y$. Since Y is finite we see that Y is a closed subset. It follows from Lemmas 19.19 and 19.20 that W is a smooth manifold with $\partial W = \partial M$. Furthermore it follows from the Complement-of-Boundary Orientation Lemma 25.16 (2) that W is still non-orientable.
(c) Since Y is a finite set and since $\dim(M) \geq 2$ we know by the elementary Exercise 18.16 that W is also path-connected.
(d) It follows from the above together with the Orientability-via-Loops Proposition 37.3 that there exists an orientation-reversing loop $\gamma\colon [0,1] \to W \setminus \partial W$ that is trivial near the ends with $\gamma(0) = \gamma(1) = x$.

By the Isotopy Extension Theorem 36.1 there exists a diffeotopy $F\colon W \times [0,1] \to W$ with the following properties:

(0) For each $t \in [0,1]$ we have $F_t(x) = \gamma(t)$.
(1) $F_0 = \mathrm{id}$.
(2) F has compact support.
(3) F is a diffeotopy rel ∂W.

Note that it follows from (2), together with Lemma 37.6, that we can extend F to a diffeotopy $F\colon M \times [0,1] \to M$ rel Y on all of M by setting $F(x,t) = x$ for $x \notin W$. Finally we set $\Phi := F_1\colon M \to M$.

By design F has properties (1), (2), (3) and (4). Furthermore it follows almost immediately from (0) and the fact that γ is orientation-reversing that (5a) is satisfied. Furthermore note that by Lemma 37.5 we know that F is actually a diffeotopy rel an open neighborhood of Y. This implies that for each $y \in Y$ we have $\mathrm{D}\Phi_y = \mathrm{id}_{\mathrm{T}_y M}$. Thus (5b) is also satisfied. ■

Proof of the Orientation-Flipping Proposition 37.4. Let $x_1, \dots, x_k$ be the elements of X. It follows from the ever useful Smooth Isotopy Transitivity Proposition 33.3 that it suffices to flip the signs of the points $x_1, \dots, x_k$ one-by-one. But this can be done by applying Lemma 37.7 altogether k times, namely to the points x_i and to the sets $Y_i := Y \cup \{x_1, \dots, \widehat{x_i}, \dots, x_k\}$. ■

37.3. **The Smooth Ball Embedding Theorem.** Our goal of this section is to prove the following theorem which was originally proved by Richard Palais [**Pal1960a**] in 1960.

Theorem 37.8. (Smooth Ball Embedding Theorem) Let M be an n-dimensional smooth manifold. (If M is orientable, then we pick an orientation for M.) In the following let $\varphi_1, \dots, \varphi_k\colon \overline{B}^n \to M \setminus \partial M$ and $\psi_1, \dots, \psi_k\colon \overline{B}^n \to M \setminus \partial M$ be two sets of k smooth embeddings of $\overline{B}^n$ with disjoint images. (If M is orientable, then we demand that all φ_i and ψ_i are orientation-preserving or that all are orientation-reversing.) If $n \geq 2$ or if $k = 1$, then there exists a diffeotopy[370]

$$G\colon M \times [0,1] \;\to\; M$$

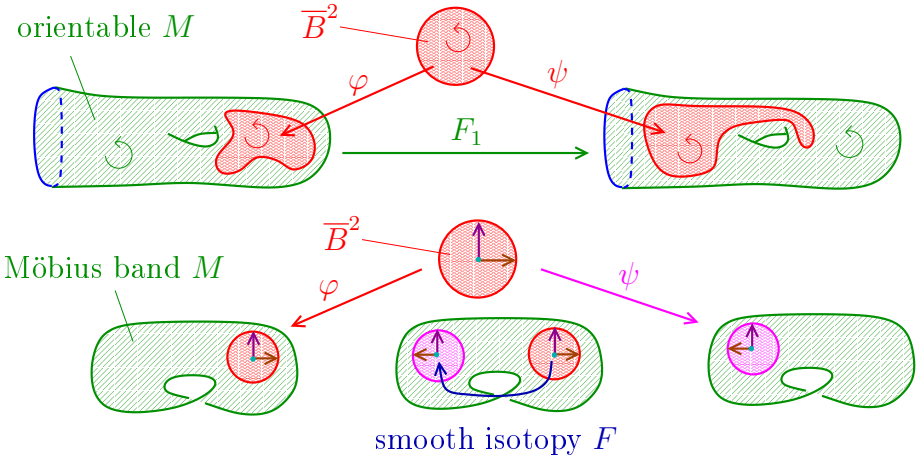
with compact support, rel some neighborhood of ∂M, from the identity $G_0 = \mathrm{id}_M$ to a diffeomorphism $G_1\colon M \to M$ such that for each $i \in \{1, \dots, k\}$ the following diagram commutes:

$$\begin{array}{ccccc} & & \overline{B}^n & & \\ & \overset{\varphi_i}{\swarrow} & & \overset{\psi_i}{\searrow} & \\ M & & \xrightarrow[\cong]{G_1} & & M. \end{array}$$

Finally, if $\varphi_i(0) = \psi_i(0)$, $i = 1, \dots, k$ and if M is orientable, then we can find a diffeotopy rel $\{\varphi_1(0), \dots, \varphi_k(0)\}$.

Remark.

(1) The Smooth Ball Embedding Theorem 37.8 has many applications, for example we will see in the Connected Sum-Proposition **??** that it can be used to show that the "connected sum" of connected orientable smooth manifolds is well-defined.
(2) On page **??** we will give a somewhat different proof of the Smooth Ball Embedding Theorem 37.8 using the Tubular Neighborhood Theorem **??**.
(3) In the Topological Ball Embedding Theorem 132.10 we will state an analogue of the Smooth Ball Embedding Theorem 37.8 in the setting of topological manifolds.



The key to proving the Smooth Ball Embedding Theorem 37.8 is the following proposition.

Proposition 37.9. Let M be a connected n-dimensional smooth manifold. (If M is orientable, then we pick an orientation for M.) In the following let $\varphi_1, \dots, \varphi_k \colon \overline{B}^n \to M \setminus \partial M$ and $\psi_1, \dots, \psi_k \colon \overline{B}^n \to M \setminus \partial M$ be two sets of k smooth embeddings of $\overline{B}^n$ with disjoint images. (If M is orientable, then we demand that all φ_i and all ψ_i are orientation-preserving or that all are orientation-reversing.) If $n \geq 2$ or if $k = 1$, then the smooth embeddings[371]

$$\bigsqcup_{i=1}^{k} \varphi_i \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \setminus \partial M \qquad \text{and} \qquad \bigsqcup_{i=1}^{k} \psi_i \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \setminus \partial M$$

are smoothly isotopic.

Remark. In the language of page 830 we can say that Proposition 37.9 calculates $\operatorname{Emb}(\overline{B}^n, M^n)$.

Proof of the Smooth Ball Embedding Theorem 37.8 assuming Proposition 37.9. By Proposition 37.9 there exists a smooth isotopy

$$F \colon \left(\bigsqcup_{i=1}^{k} \overline{B}_i^n \right) \times [0,1] \to M$$

with $F_0 = \varphi_1 \sqcup \dots \sqcup \varphi_k$ and $F_1 = \psi_1 \sqcup \dots \sqcup \psi_k$. Furthermore a quick look at the proof of Proposition 37.9 shows that if $\varphi_i(0) = \psi_i(0)$, $i = 1, \dots, k$ and if M is orientable, then

[370] Again note that if M is orientable, then the diffeomorphism G_1 is in fact orientation-preserving by the Smooth Isotopy-Orientation Proposition 34.2.
[371] Since the $\overline{B}^n$ is compact we obtain from Lemma 24.11 that k smooth embeddings of $\overline{B}^n$ with disjoint images give rise to a smooth embedding of the disjoint union of k closed balls.

we can find a smooth isotopy rel the origins of the k balls. Finally, using the Trivial-Near-The-Ends-Lemma 33.4 we can arrange that F is actually trivial near the ends.

We now apply the Isotopy Extension Theorem 36.1 to the smooth isotopy F and we obtain a diffeotopy $G\colon M \times [0,1] \to M$ with all the desired properties. ■

Proof of Proposition 37.9 if M is orientable. Note that after possibly precomposing all the smooth embeddings $\overline{B}^n \to M$ with the reflection in a hyperplane we only need to consider the case that all smooth embeddings are orientation-preserving.

We denote by $\iota\colon \overline{B}^n \to \overline{B}^n_2(0)$ the inclusion map. We pick orientation-preserving smooth embeddings $\{\Theta_i\colon \overline{B}^n_2(0) \to M \setminus \partial M\}_{i=1,\dots,k}$ with disjoint images. By the Smooth Isotopy Transitivity Proposition 33.3 it suffices to show that any orientation-preserving smooth embedding

$$\bigsqcup_{i=1}^k \alpha_i\colon \bigsqcup_{i=1}^k \overline{B}^n \to M \qquad \text{is smoothly isotopic to the smooth embedding} \qquad \bigsqcup_{i=1}^k \Theta_i \circ \iota\colon \bigsqcup_{i=1}^k \overline{B}^n \to M.$$

This statement follows from the subsequent three claims together with the Smooth Isotopy Transitivity Proposition 33.3.

Claim 1. The smooth embedding

$$\bigsqcup_{i=1}^k \alpha_i\colon \bigsqcup_{i=1}^k \overline{B}^n \to M \quad \text{is smoothly isotopic to a smooth embedding} \quad \bigsqcup_{i=1}^k \beta_i\colon \bigsqcup_{i=1}^k \overline{B}^n \to M$$

such that for each $i \in \{1,\dots,k\}$ we have $\beta_i(0) = \Theta_i(0)$.

Proof. Recall that we assume that $n \geq 2$ or that $k = 1$. Also recall that the α_i and Θ_i take values in $M \setminus \partial M$, which implies in particular that the points $\alpha_i(0)$ and $\Theta_i(0)$ lie in $M \setminus \partial M$. Since M is by hypothesis connected it follows from the Homogeneous-via-Diffeotopies Proposition 33.14 and Exercise 33.8[372] that there exists a diffeotopy $F\colon M \times [0,1] \to M$ with $F_0 = \mathrm{id}$ and such that $F_1(\alpha_i(0)) = \Theta_i(0)$ for $i = 1,\dots,k$. For $i = 1,\dots,k$ we set $\beta_i := F_1 \circ \alpha_i$ and we have found the desired smooth embeddings. ⊞

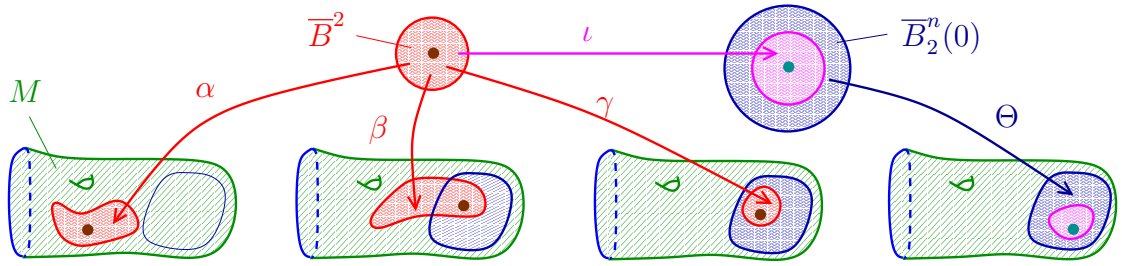
Claim 2. The smooth embedding

$$\bigsqcup_{i=1}^k \beta_i\colon \bigsqcup_{i=1}^k \overline{B}^n \to M \quad \text{is smoothly isotopic to a smooth embedding} \quad \bigsqcup_{i=1}^k \gamma_i\colon \bigsqcup_{i=1}^k \overline{B}^n \to M$$

such that for each $i \in \{1,\dots,k\}$ we have $\gamma_i(\overline{B}^n) \subset \Theta_i(B^n_2)$.

Proof. Let $i \in \{1,\dots,k\}$. Since Θ_i is a smooth embedding of an n-dimensional ball into an n-dimensional smooth manifold we obtain from the Codimension-Zero Smooth Embedding Proposition 24.16 that $\Theta_i(B^n_2(0))$ is an open subset of M. Since $\beta_i(0) = \Theta_i(0)$ we see that there exists an $\epsilon_i > 0$ such that $\beta_i(\overline{B}^n_{\epsilon_i}) \subset \Theta_i(B^n_2)$. We consider the smooth isotopy

$$\begin{array}{rcl} B_i\colon \overline{B}^n \times [0,1] & \to & M \\ (x,t) & \mapsto & \beta_i(x \cdot ((1-t) + t \cdot \epsilon_i)). \end{array}$$



This map is a smooth isotopy from β_i to a map $\gamma_i\colon \overline{B}^n \to M$ with $\gamma_i(\overline{B}^n) \subset \Theta_i(B^n_2(0))$. Since these smooth isotopies it follows from Lemma 24.11 that we have disjoint images we have found the desired smooth isotopy. ⊞

[372] Alternatively one could also use Proposition 36.4

Claim 3. The smooth embedding

$$\bigsqcup_{i=1}^{k} \gamma_i \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \quad \text{is smoothly isotopic to the smooth embedding} \quad \bigsqcup_{i=1}^{k} \Theta_i \circ \iota \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M.$$

Proof. Let $i \in \{1, \dots, k\}$. Note that by the Smooth Embedding Theorem 24.10 together with the Codimension-Zero Smooth Embedding Proposition 24.16 we know that $\Theta_i(B_2^n(0))$ is an open subset of M and we know that $\Theta_i \colon B_2^n(0) \to \Theta_i(B_2^n(0))$ is a diffeomorphism. Therefore we can consider the inverse $\Theta_i^{-1} \colon \Theta_i(B_2^n(0)) \to B_2^n(0)$. Since we arranged that $\gamma_i(\overline{B}^n) \subset \Theta_i(B_2^n(0))$ we can consider the corresponding orientation-preserving smooth embedding $\Theta_i^{-1} \circ \gamma_i \colon \overline{B}^n \to B_2^n(0)$. By the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2) we know that $\Theta_i^{-1} \circ \gamma_i \colon \overline{B}^n \to B_2^n(0)$ is smoothly isotopic in $B_2^n(0)$ to the orientation-preserving smooth embedding $\iota \colon \overline{B}^n \to B_2^n(0)$. Therefore γ_i is smoothly isotopic in $\Theta_i(B_2^n(0))$ to $\Theta_i \circ \iota$. Since the $\Theta_i(\overline{B}_2^n(0))$ are disjoint we are done. ∎

Proof of Proposition 37.9 if M is non-orientable. Suppose that M is non-orientable. As before we denote by $\iota \colon \overline{B}^n \to \overline{B}_2^n(0)$ the inclusion map. We pick smooth embeddings $\{\Theta_i \colon \overline{B}_2^n(0) \to M \setminus \partial M\}_{i=1,\dots,k}$ with disjoint images. By the Smooth Isotopy Transitivity Proposition 33.3 it suffices to show that any smooth embedding

$$\bigsqcup_{i=1}^{k} \alpha_i \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \qquad \text{is smoothly isotopic to the map} \qquad \bigsqcup_{i=1}^{k} \Theta \circ \iota \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M.$$

This statement follows again from three claims together with the Smooth Isotopy Transitivity Proposition 33.3.

Before we can state the first claim we need to introduce one new notion. We say that two smooth embeddings $\mu, \nu \colon \overline{B}^n \to M$ are *compatible* if $\mu(0) = \nu(0)$ and if the automorphism $(\mathrm{D}\nu_0)^{-1} \circ \mathrm{D}\mu_0$ of $\mathrm{T}_0\overline{B}^n$ is orientation-preserving.

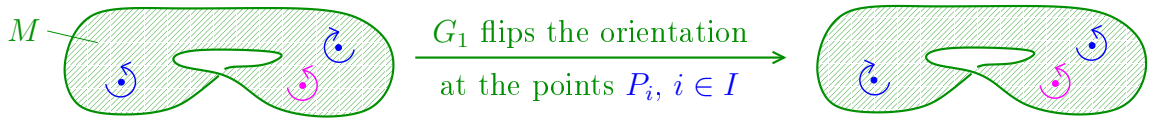
Now we can move to the modified three claims.

Claim 1. The smooth embedding

$$\bigsqcup_{i=1}^{k} \alpha_i \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \quad \text{is smoothly isotopic to a smooth embedding} \quad \bigsqcup_{i=1}^{k} \beta_i \colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M$$

such that for $i = 1, \dots, k$ the smooth embeddings β_i and $\Theta_i \circ \iota$ are compatible.

Proof. As in the oriented case we obtain from Proposition 36.4 that there exists a diffeotopy $F \colon M \times [0,1] \to M$ with $F_0 = \mathrm{id}$ and such that $(F_1 \circ \alpha_i)(0) = (\Theta_i \circ \iota)(0)$ for $i = 1, \dots, k$. For $i = 1, \dots, k$ we set $P_i := (\Theta_i \circ \iota)(0)$. Next we define



$$I := \{i \in \{1, \dots, k\} \mid \text{the smooth embeddings } F_1 \circ \alpha_i \text{ and } \Theta_i \circ \iota \text{ are not compatible}\}.$$

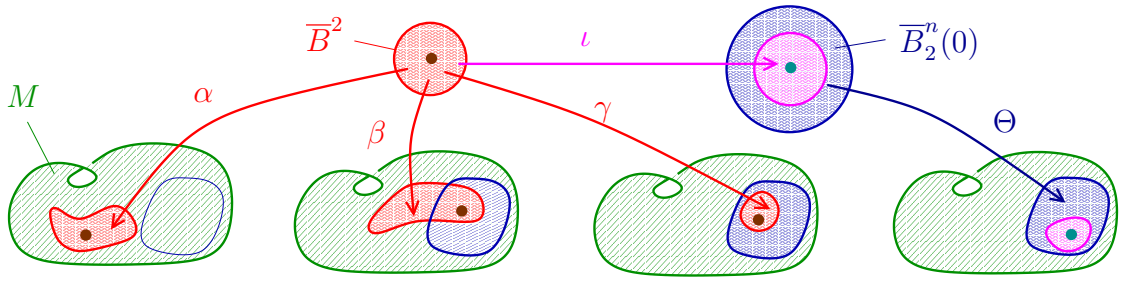
[372] On page 674 we defined what it means for an *automorphism* of a finite dimensional real vector space to be orientation-preserving.

From the Orientation-Flipping Proposition 37.4 we obtain a diffeotopy $G\colon M \times [0,1] \to M$ with $G_0 = \mathrm{id}$ with the following two properties:

(1) for all $i \in \{1,\dots,k\}$ we have $G_1(P_i) = P_i$,
(2) the map $\mathrm{D}(G_1)_{P_i}\colon \mathrm{T}_{P_i}M \to \mathrm{T}_{P_i}M$ is orientation-preserving if and only if $i \in I$.

For $i = 1,\dots,k$ we now set $\beta_i := G_1 \circ (F_1 \circ \alpha_i)$. It follows easily from (1) and (2), together with the ever-useful Smooth Isotopy Transitivity Proposition 33.3, that these smooth embeddings $\beta_1,\dots,\beta_k$ have the desired properties. ⊞

Claim 2. The smooth embedding



$$\bigsqcup_{i=1}^{k} \beta_i\colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \quad \text{is smoothly isotopic to a smooth embedding} \quad \bigsqcup_{i=1}^{k} \gamma_i\colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M$$

such that for each $i \in \{1,\dots,k\}$ we have $\gamma_i(\overline{B}^n) \subset \Theta_i(B_2^n)$ and such that for $i = 1,\dots,k$ the smooth embeddings γ_i and $\Theta_i \circ \iota$ are compatible.

Proof. The construction of the γ_i follows by the same recipe as in the oriented case. It is basically clear from the construction that for $i = 1,\dots,k$ the smooth embeddings γ_i and $\Theta_i \circ \iota$ are indeed compatible. ⊞

Claim 3. The map

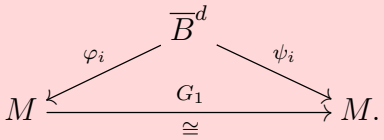
$$\bigsqcup_{i=1}^{k} \gamma_i\colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M \quad \text{is smoothly isotopic to the smooth embedding} \quad \bigsqcup_{i=1}^{k} \Theta_i \circ \iota\colon \bigsqcup_{i=1}^{k} \overline{B}^n \to M.$$

Proof. Let $i \in \{1,\dots,k\}$. Since $\gamma_i(\overline{B}^n) \subset \Theta_i(B_2^n(0))$ we can consider the corresponding smooth embedding $\iota \circ \Theta_i^{-1} \circ \gamma_i\colon \overline{B}^n \to B_2^n(0)$. We consider the following diagram:

$$\begin{array}{ccccc} & & \mathrm{T}_0 B_2^n(0) & & \\ & \overset{\mathrm{D}(\Theta^{-1}\circ\gamma_i)_0}{\nearrow} & \cong & \overset{\mathrm{D}\iota_0}{\nwarrow} & \\ \mathrm{T}_0\overline{B}^n & & \cong & & \mathrm{T}_0\overline{B}^n. \\ & \underset{(\mathrm{D}(\Theta_i\circ\iota)_0)^{-1}\circ\mathrm{D}(\gamma_i)_0}{\longrightarrow} & & & \end{array}$$

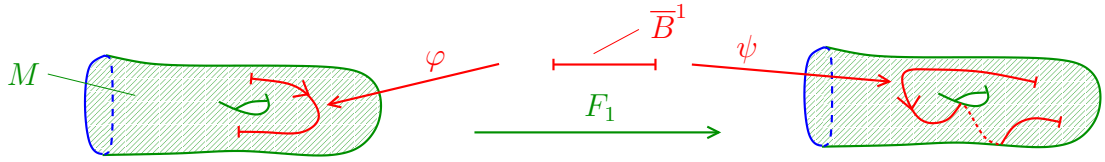
Note that the diagram commutes by default. Since γ_i and $\Theta_i \circ \iota$ are compatible the bottom map is orientation-preserving. By definition of the orientations on $\overline{B}^n$ and $B_2^n(0)$ the right diagonal map is orientation-preserving. It follows that the left diagonal map is orientation-preserving. By the Basics-of-Orientations Lemma 25.13 (3) this implies that the smooth

embedding $\Theta_i^{-1} \circ \gamma_i$ is orientation-preserving. At this point the argument proceeds as in the oriented case.



Indeed, by the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2) we now know that $\Theta_i^{-1} \circ \gamma_i \colon \overline{B}^n \to B_2^n(0)$ is smoothly isotopic in $B_2^n(0)$ to the orientation-preserving smooth embedding $\iota \colon \overline{B}^n \to B_2^n(0)$. Therefore γ_i is smoothly isotopic in $\Theta_i(B_2^n(0))$ to $\Theta_i \circ \iota$. Since the $\Theta_i(\overline{B}_2^n(0))$ are disjoint we are done. ■

37.4. **The Lower-Dimensional Smooth Ball Embedding Theorem.** We also have a uniqueness theorem for smooth embeddings of lower dimensional balls. In fact it is slightly easier to state than the Smooth Ball Embedding Theorem 37.8 since we will not care about orientations.



Theorem 37.10. (Lower-Dimensional Smooth Ball Embedding Theorem) Let M be an n-dimensional smooth manifold and let $d \in \{0, \dots, n-1\}$. In the following let $\varphi_1, \dots, \varphi_k \colon \overline{B}^d \to M \setminus \partial M$ and $\psi_1, \dots, \psi_k \colon \overline{B}^d \to M \setminus \partial M$ be two sets of k smooth embeddings of $\overline{B}^d$ with disjoint images. If $n \geq 2$ or if $k = 1$, then there exists a diffeotopy

$$G \colon M \times [0,1] \to M$$

with compact support, rel some neighborhood of ∂M, from the identity $G_0 = \mathrm{id}_M$ to a diffeomorphism $G_1 \colon M \to M$ such that for each $i \in \{1, \dots, k\}$ the following diagram commutes:

Finally, if $\varphi_i(0) = \psi_i(0)$, $i = 1, \dots, k$ and if M is orientable, then we can find a diffeotopy rel $\{\varphi_1(0), \dots, \varphi_k(0)\}$.

Remark.

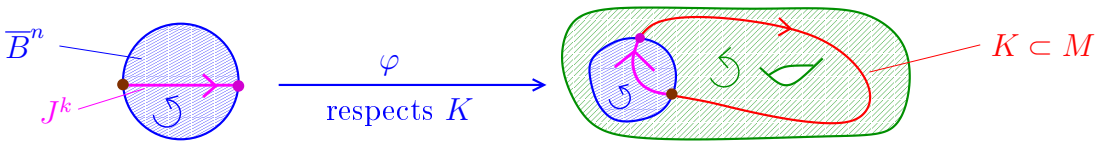
(1) In the language of page 830 we can say that the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 calculates $\mathrm{Emb}(\overline{B}^d, M^n)$ for $d < n$.
(2) The case $d = 0$ is precisely the content of the Homogeneous-via-Diffeotopies Proposition 36.4.

Proof. The same that we deduced the Smooth Ball Embedding Theorem 37.8 from Proposition 37.9 we can now deduce the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 from the following claim.

Claim. If $n \geq 2$ or if $k = 1$, then the smooth embeddings

$$\bigsqcup_{i=1}^k \varphi_i \colon \bigsqcup_{i=1}^k \overline{B}^d \to M \setminus \partial M \qquad \text{and} \qquad \bigsqcup_{i=1}^k \psi_i \colon \bigsqcup_{i=1}^k \overline{B}^d \to M \setminus \partial M$$

are smoothly isotopic.



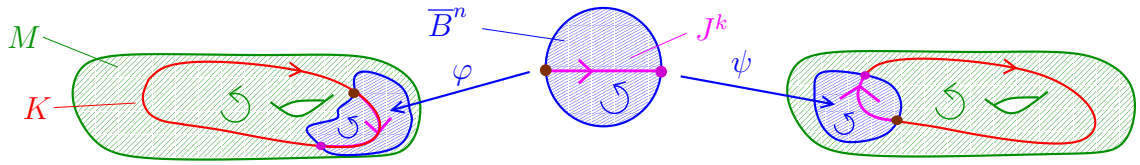
Proof. The proof of the claim is basically identical to the proof of Proposition 37.9 in the orientable case. All we have to do is to replace the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2) by the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (3). We leave it to the reader to fill in the details. ■

Finally we want to consider a variation on the Smooth Ball Embedding Theorem 37.8 and the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 where we look at smooth embeddings of balls that "respect" a submanifold. This discussion is perhaps a little peripheral, but it plays a role when later on we introduce the connected sum of submanifolds and knots.

Definition. Let $n \in \mathbb{N}$ and let $k \in \{0, \dots, n\}$.

(1) We set $J^k := \{(x,0) \in \overline{B}^n \mid x \in \overline{B}^k\} = \overline{B}^n \cap (\mathbb{R}^k \times \{0\})$ and we view equip J^k with the obvious orientation.

(2) Let M be an oriented n-dimensional smooth manifold and let $K \subset M$ be an oriented k-dimensional submanifold. Furthermore let $\varphi\colon \overline{B}^n \to M$ be a smooth embedding. We say φ respects K if $\varphi(\overline{B}^n) \subset M \setminus \partial M$, if $\varphi(J^k) = \varphi(\overline{B}^n) \cap K$, if $\varphi\colon \overline{B}^n \to M$ is orientation-preserving and if $\varphi|_{J^k}\colon J^k \to \varphi(\overline{B}^n) \cap K$ is orientation-preserving.



The following theorem gives a uniqueness statement for smooth embeddings of balls that respect a given submanifold.[373]

Theorem 37.11. Let M be an oriented n-dimensional smooth manifold. Furthermore let $K \subset M$ be a connected oriented k-dimensional submanifold. Finally let $\varphi\colon \overline{B}^n \to M$ and $\psi\colon \overline{B}^n \to M$ be two smooth embeddings that respect K. There exists a diffeotopy

$$G\colon M \times [0,1] \to M$$

with compact support, rel some neighborhood of ∂M, from the identity $G_0 = \mathrm{id}_M$ to a diffeomorphism $G_1\colon M \to M$ such that $G_1 \circ \varphi = \psi$ and such that each $G_t \circ \varphi\colon \overline{B}^n \to M$ respects K.

Sketch of proof. As in the proofs of the Smooth Ball Embedding Theorem 37.8 and of the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 it suffices to prove the following claim.

[373] The case $K = M$ is in fact the statement of Smooth Ball Embedding Theorem 37.8 in the orientation-preserving case.

Claim. For any two smooth embeddings $\varphi\colon \overline{B}^n \to M$ and $\psi\colon \overline{B}^n \to M$ that respect K there exists a smooth isotopy $F\colon \overline{B}^n \times [0,1] \to M$ such that $F_0 = \varphi$, such that $F_1 = \psi$ and such that each $F_t \circ \varphi$ respects K.

Proof. The proof of the theorem is a modification of the proof of Proposition 37.9. Evidently now one has to go through the proof of Proposition 37.9, and of all the sources it uses, to make the necessary changes. It seems to this author that most modifications are straightforward, except for possibly one step. Let us elaborate.

Let $f\colon \overline{B}^n \to \mathbb{R}^n$ be a map that respects $K := \mathbb{R}^k \times \{0\}$ and such $f(0) = 0$. We write $A := \mathrm{D}f_0$ and we denote by $\mu(A)\colon \overline{B}^n \to \mathbb{R}^n$ the map that is given by multiplication by A. The fact that f respects K implies that A is of the form $\begin{pmatrix} * & * \\ 0 & * \end{pmatrix}$, where the top left corner is a $(k \times k)$-matrix. It follows fairly easily that $\mu(A)$ also respects $K = \mathbb{R}^k \times \{0\}$. Similar to the discussion on page 834 we need to prove the following claim.

Claim. There exists a smooth isotopy $F\colon \overline{B}^n \to \mathbb{R}^n$ with $F_0 = f$, $F_1 = \mu(A)$ and such that each F_t respects $K = \mathbb{R}^k \times \{0\}$

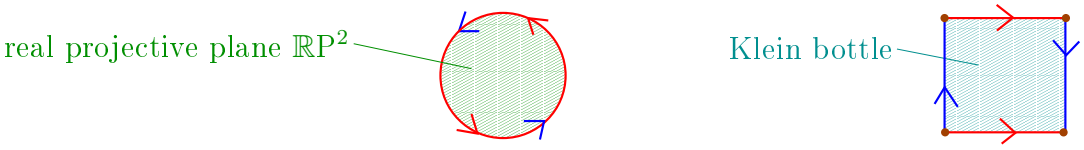
Proof. Since $\overline{B}^n$ is a convex subset of $\mathbb{R}^n$ that contains the origin, since $f(0) = 0$ and since f respects $K = \mathbb{R}^k \times \{0\}$ we know by the Map-as-Matrix Multiplication Proposition 19.14 (1) and (2) that there exists a smooth map $\Theta\colon \mathbb{R}^n \to \mathrm{M}(n \times n, \mathbb{R})$ with the following properties:

(1) we have $\Theta(0) = A = \mathrm{D}f_0$,
(2) for all $x \in \mathbb{R}^n$ we have $f(x) = \Theta(x) \cdot x$, and
(3) for all $x \in J^k$ we have $\Theta(x) = \begin{pmatrix} * & * \\ 0 & * \end{pmatrix}$, where the top left square is a $k \times k$-matrix.

As on page 834 we consider the map

$$\begin{array}{rcl} F\colon \overline{B}^n \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & \underbrace{\Theta(t \cdot x)}_{\in \mathrm{M}(n \times n, \mathbb{R})} \cdot x. \end{array}$$

As on page 834 we see that F is an isotopy with $F_0 = f$ and $F_1 = \mu(A)$. But now the above property (3) implies that each F_t respects $K = \mathbb{R}^k \times \{0\}$. ⊞



We leave all other details of the proof of Theorem 37.11 to the unquenchable thirst of the reader for technical details. ■

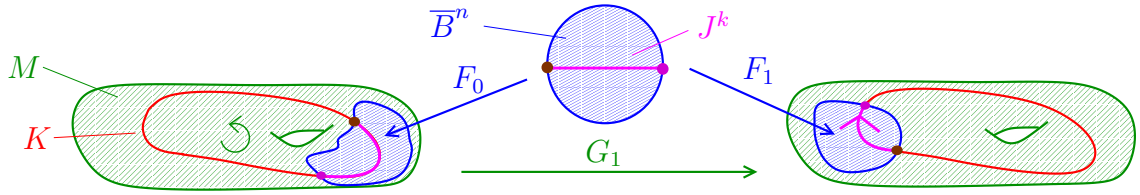
Exercises for Chapter 37.

Exercise 37.1. We consider the

$$\begin{array}{rcll} \text{real projective plane } \mathbb{R}\mathrm{P}^2 & = & \overline{B}^2/\sim & \text{where } x \sim -x \text{ for } x \in S^1 \\ \text{Klein bottle } K & = & ([0,1] \times [0,1])/\sim & \text{where } (x,0) \sim (x,1) \text{ and } (0,y) \sim (1,1-y). \end{array}$$

In both cases give examples of orientation-reversing loops.

Exercise 37.2. Let M be a smooth manifold and let $\gamma, \delta\colon [0,1] \to M \setminus \partial M$ be smooth loops that are trivial near the ends with $\gamma(0) = \gamma(1) = \delta(0) = \delta(1)$. We consider the concatenation

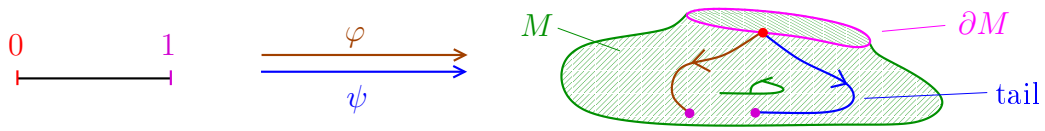


$$\begin{array}{rcl} \gamma * \delta\colon [0,1] & \to & M \\ t & \mapsto & \begin{cases} \gamma(2t), & \text{if } t \in [0, \frac{1}{2}], \\ \delta(2t-1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

Show that $\gamma * \delta$ is orientation-preserving if and only if either both γ and δ are orientation-preserving or both are orientation-reversing.

Exercise 37.3. Let $n \in \mathbb{N}$ and let $k \in \{0, \dots, n\}$. We set $J^k := \{(x,0) \in \overline{B}^n \mid x \in \overline{B}^k\}$. Let N be an n-dimensional smooth manifold and let $K \subset N$ be an k-dimensional submanifold. As on page 894 we say that a smooth embedding $\varphi\colon \overline{B}^n \to N$ *respects* K if $\varphi(\overline{B}^n) \subset N \setminus \partial N$ and if $\varphi(J^k) = \varphi(\overline{B}^n) \cap K$. Let $F\colon \overline{B}^n \times [0,1] \to N$ be a smooth isotopy such that each F_t respects K. Show that there exists a diffeotopy $G\colon N \times [0,1] \to N$ with the following properties:

(1) $G_0 = \mathrm{id}$.
(2) For all $x \in \overline{B}^n$ and all $t \in [0,1]$ we have $G(F_0(x), t) = F(x,t)$.
(3) For all $t \in [0,1]$ the map G_t restricts to a diffeomorphism of K.

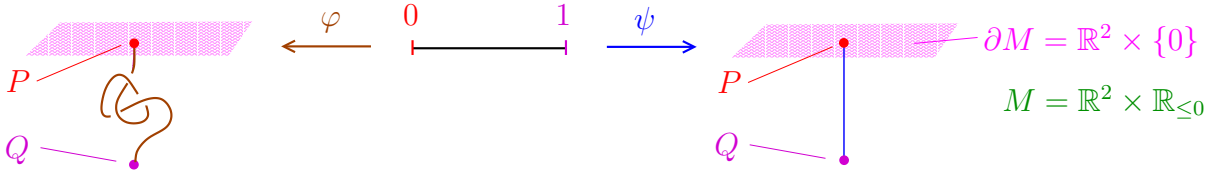


Remark. Evidently you are supposed to at least outline how to modify the proof of the Isotopy Extension Theorem 36.1 to obtain the desired diffeotopy.

Exercise 37.4. Let M be a smooth manifold and let $P \in \partial M$. A *tail at* P is a smooth embedding $\varphi\colon [0,1] \to M$ with the following properties:

(1) $\varphi(0) = P$ and $\varphi^{-1}(\partial M) = \{0\}$,
(2) $\varphi'(0) \notin \mathrm{T}_{\varphi(0)}(\partial M)$.

Show that if $\varphi, \psi\colon [0,1] \to M$ are two tails at P, then they are "smoothly isotopic as tails", i.e. show that there exists a smooth map $F\colon [0,1] \times [0,1] \to M$ with $F_0 = \varphi$, $F_1 = \psi$ and such that each F_t is a tail at P.



Exercise 37.5. Let M be a smooth manifold and let $P \in \partial M$. As in Exercise 37.4 we define a *tail at* P to be a smooth embedding $\varphi\colon [0,1] \to M$ with the following properties:

(1) $\varphi(0) = P$ and $\varphi^{-1}(\partial M) = \{0\}$,
(2) $\varphi'(0) \notin \mathrm{T}_{\varphi(0)}(\partial M)$.

Solve the following two problems:

(a) Show that if $\varphi, \psi\colon [0,1] \to M$ are two tails at P with the same endpoint, i.e. such that $\varphi(1) = \psi(1)$, then one tail can be turned into the other while keeping the endpoints fixed. More precisely, show that there exists a smooth homotopy $F\colon [0,1]\times[0,1] \to M$ rel $\{0,1\}$ with $F_0 = \varphi$, $F_1 = \psi$ and such that each F_t is a tail at P.

(b) As an explicit example consider the two tails shown in the figure below. We consider a "room" $M = \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ with "ceiling" $\partial M = \mathbb{R}^2 \times \{0\}$. Furthermore we consider two cables φ and ψ from P to Q. Show that you can turn the "twisted cable φ" into the "untwisted cable ψ" while keeping P and Q fixed.

38. The degree of a map between oriented smooth manifolds I

38.1. The definition of the degree of a map between closed smooth manifolds.

Definition. Let $f\colon M \to N$ be a smooth map between two oriented n-dimensional smooth manifolds and let $x \in M \setminus \partial M$. If f is a local diffeomorphism at x, then we define the local degree of f at the point x as[374]

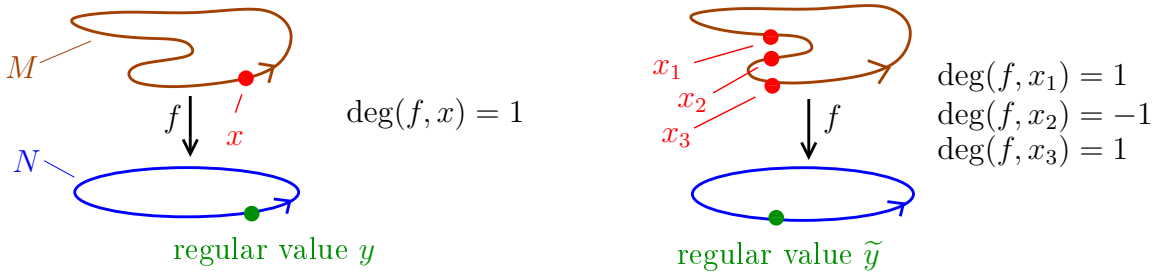
$$\deg(f,x) \;:=\; \begin{cases} +1, & \text{if } f \text{ is orientation-preserving at } x \\ -1, & \text{if } f \text{ is orientation-reversing at } x. \end{cases}$$

Remark. On page 1694 and page 2379 we will generalize the notion of local degree to maps that are not necessarily local diffeomorphisms and to suitable maps between topological manifolds.

We continue with the following simplified version of the Stack of Records Lemma 26.2.

Lemma 26.2. Let $f\colon M \to N$ be a smooth map between two closed smooth manifolds of the same dimension.

(1) For every regular value $y \in N$ the preimage $f^{-1}(y)$ is a finite subset of M.
(2) Given any regular point $x \in M$ the map $f\colon M \to N$ is a local diffeomorphism at x.



Proof.

(1) By the Regular Value Theorem 26.4 we know that $f^{-1}(y)$ is a proper 0-dimensional submanifold of the closed smooth manifold M. It follows from the discussion on page 514 that $f^{-1}(y)$ is a discrete subset of M. Since M is in particular compact it follows from the Compact-Discrete Lemma 1.22 that $f^{-1}(y)$ is actually a finite set.
(2) Let $x \in M$ be a regular point of f. This means that $\mathrm{D}f_x\colon \mathrm{T}_{f(x)}M \to \mathrm{T}_{f(x)}N$ is an epimorphism. Since M and N have the same dimension this implies that $\mathrm{D}f_x$ is an isomorphism. It follows from the Inverse Mapping Theorem 24.1 that f is a local diffeomorphism around x. ∎

Theorem 38.1. Let $f\colon M \to N$ be a smooth map between two closed oriented connected smooth manifolds of the same dimension. Let $y \in N$ be a regular value. The sum[375]

$$\sum_{x \in f^{-1}(y)} \deg(f,x) \;\in\; \mathbb{Z}$$

does not depend on the choice of y.

[374] Note that by the discussion on page 675 this definition also makes sense for 0-dimensional manifolds.
[375] We know by Lemma 26.2 that this is indeed a finite sum.

We postpone the proof of Theorem 38.1 to the next section. The theorem allows us to introduce the following definition.

Definition. Let $f\colon M \to N$ be a smooth map between two closed oriented connected non-empty smooth manifolds of the same dimension. By Sard's Theorem 31.1 there exists a regular value y. By Theorem 38.1 we can unambiguously define the degree of the smooth map f as

$$\deg(f) \;:=\; \sum_{x\in f^{-1}(y)} \deg(f,x) \;\in\; \mathbb{Z}.$$

Let $f\colon M \to N$ be a map (not necessarily smooth) between two closed oriented connected non-empty smooth manifolds of the same dimension. By the Whitney Approximation Theorem 29.1 we know that f is homotopic to a smooth map $g\colon M \to N$. The idea now is to define the degree of f as the degree of the smooth map g. For this approach to make sense we need the following proposition.

Proposition 38.2. Let $g\colon M \to N$ be a map between two closed oriented connected non-empty smooth manifolds of the same dimension. If $f_0, f_1\colon M \to N$ are smooth maps that are both homotopic to g, then $\deg(f_0) = \deg(f_1)$.

Proof. We postpone the proof of Proposition 38.2 to the next section. ■

Proposition 38.2 allows us to make the following definition.

Definition. Let $f\colon M \to N$ be a map between two closed oriented connected non-empty smooth manifolds of the same dimension. By the Whitney Approximation Theorem 29.1 we know that f is homotopic to a smooth map $g\colon M \to N$. By Proposition 38.2 it makes sense to define

$$\deg(f) \;:=\; \deg(g).$$

Remark.

(1) The notion of the degree was first introduced by Luitzen Brouwer [**Brou1912a**, p. 103], the degree is therefore sometimes also called the *Brouwer degree*.
(2) In Section 39.1 we will extend the definition of a degree to maps between smooth manifolds with non-empty boundary.
(3) On page 2222 we will use homology groups to give a different definition of the degree of a smooth map between closed oriented smooth manifolds. In the Local-Global Degree Proposition 101.6 we will see that the two definitions agree.
(4) On page 2379 we will again use homology groups to extend the notion of a degree from smooth manifolds to topological manifolds.

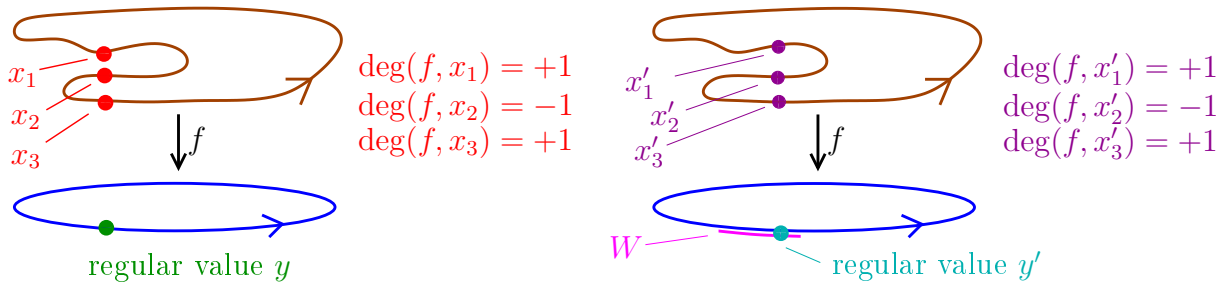
In the following two theorems we state two interesting properties of the degree.

Theorem 38.3. (Degree Homotopy Invariance Theorem) Let $f_0, f_1\colon M \to N$ be maps between two closed oriented connected non-empty smooth manifolds of the same dimension. If f_0 and f_1 are homotopic, then

$$\deg(f_0) \;=\; \deg(f_1).$$

Theorem 38.4. (Degree Multiplicativity Theorem) If $f\colon L \to M$ and $g\colon M \to N$ are maps between closed oriented connected non-empty smooth manifolds of the same

dimension, then $$\deg(g \circ f) \;=\; \deg(g) \cdot \deg(f).$$



We provide the proofs of these two theorems in the next section.

38.2. **Proof of Theorem 38.1, 38.3 and 38.4.** For the purpose of this section we introduce the following notation.

Notation. Let $f\colon M \to N$ be a smooth map between closed oriented connected non-empty smooth manifolds of the same dimension. Let $y \in N$ be a regular value. We define $$\deg^y(f) \;:=\; \sum_{x \in f^{-1}(y)} \deg(f, x) \;\in\; \mathbb{Z}.$$

The proofs of Theorem 38.1 and 38.3 rely on three lemmas which we will prove in this section. The first lemma is a slight refinement of the Stack of Records Lemma 26.2.

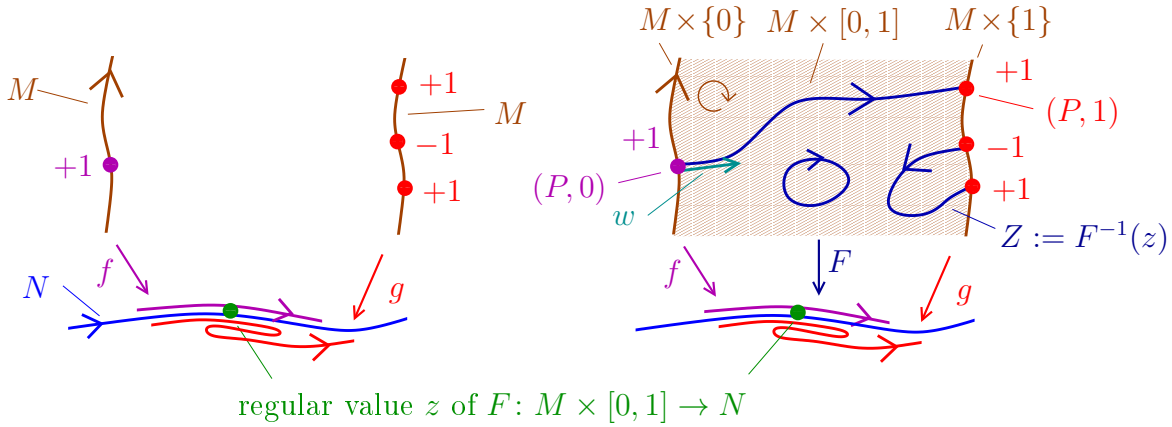
Lemma 38.5. Let $f\colon M \to N$ be a smooth map between two closed smooth manifolds of the same dimension. Every regular value $y \in N$ admits an open neighborhood W such that each $y' \in W$ is a regular value and such that for each $y' \in W$ we have $\deg^y(f) = \deg^{y'}(f)$.

Proof. Let $f\colon M \to N$ be a smooth map between two closed smooth manifolds of the same dimension and let $y \in N$ be a regular value. We denote the points in the preimage $f^{-1}(y)$ by $x_1, \ldots, x_k \in M$. Since $x_1, \ldots, x_k$ are regular points we obtain from the Inverse Mapping Theorem 24.1 connected open neighborhoods $U_1, \ldots, U_k$ of $x_1, \ldots, x_k$ such that each $f_k\colon U_k \to V_k := f(U_k)$ is a diffeomorphism. Since M is Hausdorff and since the $x_1, \ldots, x_k$ are distinct we can arrange, see the elementary Exercise 1.15, that the open neighborhood $U_1, \ldots, U_k$ are disjoint. We set

$$W \;:=\; \Big(\bigcap_{i=1}^{k} V_i\Big) \setminus \underbrace{f\Big(M \setminus \bigcup_{i=1}^{k} U_i\Big)}_{\substack{\text{closed subset of } N \\ \text{since } M \text{ is compact}}}.$$

Note that W is open and that it contains y. Now let $y' \in W$. Note that the preimage of $y' \in W$ consists of precisely k points, namely precisely one x'_i in each U_i.[376] Since the U_i are connected it follows immediately from the Basics-of-Orientations Lemma 25.13 that for each $i \in \{1, \ldots, k\}$ we have $\deg(f, x_i) = \deg(f, x'_i)$. This shows that $\deg^y(f) = \deg^{y'}(f)$. ∎

[376] This can be seen as follows. Let $y' \in W$. Let $i \in \{1, \ldots, k\}$. By definition $y' \in V_i$, thus there exists a unique preimage of y' in U_i. Since $U_1, \ldots, U_k$ are disjoint we see that y' has k preimages in $U_1 \cup \cdots \cup U_k$. By choice of W the point y' has no preimage outside of $U_1 \cup \cdots \cup U_k$.



Lemma 38.6. Let M and N be two closed oriented n-dimensional smooth manifolds. Furthermore let $f, g\colon M \to N$ be two smooth maps and let $y \in N$ be a regular value for f and for g. If f and g are smoothly homotopic, then $\deg^y(f) = \deg^y(g)$.

Proof. Let $y \in N$ be a regular value for f and for g. It follows immediately from applying Lemma 38.5 to f and g and taking the intersection of the resulting open neighborhoods of $y \in N$ that there exists an open neighborhood W of $y \in N$ such that for every $y' \in W$ we have $\deg^y(f) = \deg^{y'}(f)$ and $\deg^y(g) = \deg^{y'}(g)$.

Since W is open and non-empty we obtain from Sard's Theorem 31.1 that there exists a regular value $z \in W$ of $F\colon M \times [0,1] \to N$. Note that by the Regular Value Theorem 26.4 we know that $F^{-1}(z)$ is a compact proper 1-dimensional submanifold of $M \times [0,1]$. Furthermore we saw in the proof of the Regular Value Theorem 26.4 on page 707 that we can equip the 1-dimensional smooth manifold $Z := F^{-1}(z) \subset M \times [0,1]$ with an orientation as follows.

(1) We equip $M \times [0,1]$ with the product orientation that we introduced on page 695.
(2) We pick a positive basis $v_1, \dots, v_n$ for $\mathrm{T}_z N$.
(3) Given a point $Q \in Z = F^{-1}(z)$ we pick vectors[377] $\widetilde{v}_1, \dots, \widetilde{v}_n \in \mathrm{T}_Q(M \times [0,1])$ such that $\mathrm{D}F_Q(\widetilde{v}_i) = v_i$ for $i = i, \dots, n$. Now we say that a non-zero vector $w \in \mathrm{T}_Q Z$ is positive if $\widetilde{v}_1, \dots, \widetilde{v}_n, w$ is a positive basis for $\mathrm{T}_Q(M \times [0,1])$.

We equip ∂Z with the corresponding boundary orientation $\epsilon\colon \partial Z \to \{\pm 1\}$ given by the definition on page 688.

Claim. Let $P \in M$.[378]
(1) If $(P,0) \in \partial Z$, then $\epsilon((P,0)) = -\deg(f, P)$.
(2) If $(P,1) \in \partial Z$, then $\epsilon((P,1)) = \deg(g, P)$.

Proof. First let $(P,0) \in \partial Z$. We make the following preparations:

(i) We denote by $q\colon M \times [0,1] \to [0,1]$ the projection. Note that it follows from the fact that Z is a proper submanifold of $M \times [0,1]$ and the fact that $\mathrm{T}_{(P,0)}\partial M = \ker(\mathrm{D}q_{(P,0)})$ that the image of $\mathrm{D}q_{(P,0)}\colon \mathrm{T}_{(P,0)} Z \to \mathrm{T}_{f(P)}\mathbb{R} = \mathbb{R}$ is non-trivial.

[377] Since z is a regular value of F we know that $\mathrm{D}F_Q$ is an epimorphism.
[378] Recall that our definition of a regular value, see page 701, entails that z is also a regular value of the restriction of F to $\partial(M \times [0,1])$, in other words, it is a regular value of $F_0 = f\colon M \to N$ and $F_1 = g\colon M \to N$. In particular $\deg(f, P)$ and $\deg(g, P)$ are actually defined.

(ii) By (i) we can pick $w \in \mathrm{T}_{(P,0)}Z$ with $\mathrm{D}q_{(P,0)}(w) > 0$.
(iii) Recall that our definition of a regular value, see page 701, entails that the differential $\mathrm{D}F_{(P,0)}\colon \mathrm{T}_{(P,0)}(M \times \{0\}) \to \mathrm{T}_{F(P,0)}N$ is also an epimorphism. Therefore we can actually pick vectors $\widetilde{v}_1, \dots, \widetilde{v}_n \in \mathrm{T}_{(P,0)}(M \times \{0\})$ such that $\mathrm{D}F_{(P,0)}(\widetilde{v}_i) = v_i$ for $i = i, \dots, n$.
(iv) We denote by $\iota\colon M \to M \times [0,1]$ the inclusion given by $x \mapsto (x, 0)$.
(v) For $i = 1, \dots, n$ we pick $\widetilde{u}_i \in \mathrm{T}_P M$ such that $\mathrm{D}\iota_P(\widetilde{u}_i) = v_i$.

Now we see that the following statements are equivalent:

we apply the definition of the boundary orientation from page 688 to $\gamma := q\colon Z \to \mathbb{R}_{\geq 0}$
note that $\gamma((P,0)) = 0$ and $\mathrm{D}\gamma_{(P,0)}(w) = \mathrm{D}q_{(P,0)}(w) > 0$

$$\epsilon((P,0)) = -1 \overset{\downarrow}{\iff} w \in \mathrm{T}_{(P,0)}Z \text{ is a positive vector}$$
$$\iff \widetilde{v}_1, \dots, \widetilde{v}_n, w \text{ is a positive basis for } \mathrm{T}_{(P,0)}(M \times [0,1])$$
$$\overset{\uparrow}{\iff} \widetilde{u}_1, \dots, \widetilde{u}_n \text{ is a positive basis for } \mathrm{T}_P M \overset{\uparrow}{\iff} \mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N \text{ is orientation-preserving} \overset{\uparrow}{\iff} \deg(f,P) = +1.$$

follows from $\mathrm{D}q_{(P,0)}(w) > 0$ and the definition of the product orientation, see the Product Orientation Proposition 25.22

since $F_0 \circ \iota = f$ and since $v_1, \dots, v_n$ is a positive basis for $\mathrm{T}_{f(P)}N$

by definition of $\deg(f,P)$

Since ϵ and deg take values in $\{\pm 1\}$ we are actually done with the proof of (1).

Now suppose that we are given a point $(P,1) \in \partial Z$. The argument is very similar to the above. Again we can and will pick $w \in \mathrm{T}_{(P,1)}W$ with $\mathrm{D}q_{(P,1)}(w) > 0$. Now we see that the following statements are equivalent:

we apply the definition of the boundary orientation from page 688 to $\gamma(t) := q(1-t)\colon Z \to \mathbb{R}_{\geq 0}$
note that $\gamma((P,1)) = 0$ and $\mathrm{D}\gamma_{(P,1)}(w) = -\mathrm{D}q_{(P,0)}(w) < 0$

$$\epsilon((P,1)) = +1 \overset{\downarrow}{\iff} w \in \mathrm{T}_{(P,1)}W \text{ is a positive vector} \overset{\uparrow}{\iff} \dots \overset{\uparrow}{\iff} \deg(g,P) = +1.$$

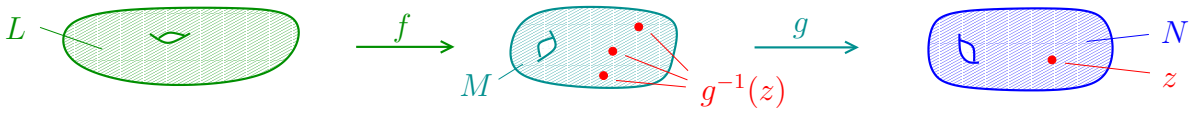
precisely as above

This concludes the proof of (2). ⊞

Now we can easily complete the argument, namely we perform the following calculation:

$$\deg^y(f) - \deg^y(g) \overset{\uparrow}{=} \deg^z(f) - \deg^z(g) \overset{\uparrow}{=} \sum_{P \in \partial Z \cap (M \times \{0\})} \epsilon(P) + \sum_{P \in \partial Z \cap (M \times \{1\})} \epsilon(P) \overset{\uparrow}{=} 0.$$

since $z \in W$



by the claim

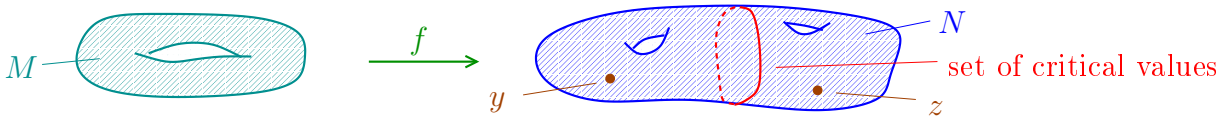
by the Boundary-of-Compact 1-Dimensional Smooth Manifold Proposition 25.18 we know that the sum over the orientations of ∂Z is zero, the equality thus follows from the fact that $\partial Z \subset M \times \{0,1\}$

We have thus shown that $\deg^y(f) = \deg^y(g)$. ■

Lemma 38.7. Let $f\colon L \to M$ and $g\colon M \to N$ be two smooth maps between closed oriented connected non-empty smooth manifolds of the same dimension. If $z \in N$ is a regular value of $g\colon M \to N$ such that each point in $g^{-1}(z) \subset M$ is a regular value of $f\colon L \to M$, then

$$\deg^z(g \circ f) = \sum_{y \in g^{-1}(z)} \deg(g,y) \cdot \deg^y(f).$$

Proof. We perform the following calculation:



$$\deg^z(g\circ f) = \sum_{x\in(g\circ f)^{-1}(z)} \deg(g\circ f,x) \overset{\text{by the Orientation-Composition Lemma 25.3 we have } \deg(g\circ f,x)=\deg(g,f(x))\cdot\deg(f,x)}{\downarrow =} \sum_{y\in g^{-1}(z)}\sum_{x\in f^{-1}(y)} \deg(g,y)\cdot\deg(f,x)$$
$$= \sum_{y\in g^{-1}(z)} \deg(g,y)\cdot \underbrace{\sum_{x\in f^{-1}(y)} \deg(f,x)}_{=\deg^y(f)}.$$

■

After these preparations we can finally provide the proofs of Theorem 38.1, 38.3 and 38.4.

Proof of Theorem 38.1. Let $f\colon M\to N$ be a smooth map between two closed oriented connected non-empty smooth manifolds of the same dimension. Let $y\in N$ and $z\in N$ be regular values of f. We need to show that $\deg^y(f)=\deg^z(f)$.

The first idea might be to try to connect y and z via a path and to use this path to show that the two degrees are the same. But this approach is doomed to fail since in general the set of regular values is *not* path-connected. Thus we need to use a different approach.

By the Homogeneous-via-Diffeotopies Proposition 33.14 we know that there exists a diffeotopy $F\colon N\times[0,1]\to N$ with $F_0=\mathrm{id}$ and such that $F_1(y)=z$. We now obtain the following equalities:

$$\deg^y(f) = \underbrace{\deg(F_1,y)}_{\substack{=1 \text{ since it follows from the Smooth Isotopy-Orientation Proposition 34.2 that } F_1 \text{ is an orientation-preserving diffeomorphism}}} \cdot \deg^y(f) \overset{\substack{\text{by Lemma 38.7, since } F_1 \text{ is a diffeomorphism and since } y \text{ is a regular value of } f}}{\downarrow =} \deg^{F_1(y)}(F_1\circ f) \overset{\text{since } F_1(y)=z}{\downarrow =} \deg^z(F_1\circ f) \underset{\substack{\uparrow \\ \text{follows from Lemma 38.6, since } F_1\circ f \text{ and } F_0\circ f=f \text{ are smoothly homotopic and since } z \text{ is a regular value of } F_1\circ f \text{ and of } f}}{=} \deg^z(f).$$

■

Proof of Proposition 38.2. Let $g\colon M\to N$ be a map between two closed oriented connected non-empty smooth manifolds of the same dimension and let $f_0,f_1\colon M\to N$ be smooth maps that are both homotopic to g. We need to show that $\deg(f_0)=\deg(f_1)$.

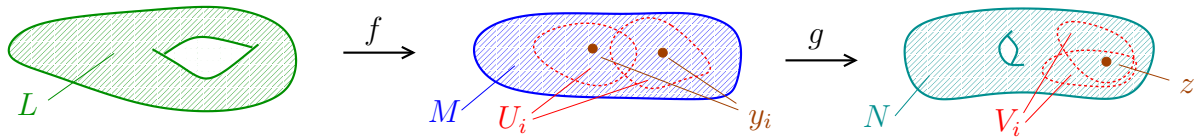
It follows from the transitivity of being homotopic, see the Homotopy-Equivalence Basics Lemma 15.1, that f_0 and f_1 are homotopic. Furthermore it follows from the Replace-by-Smooth Homotopy Proposition 29.5 that f_0 and f_1 are actually smoothly homotopic.

Next note that it follows from Sard's Theorem 31.1 together with the Full Measure-Density Proposition 30.3 that we can find a $z\in N$ which is a regular value for f_0 and also for f_1. Thus it follows from Lemma 38.6 that $\deg(f_0)=\deg(f_1)$. ■

Proof of the Degree Homotopy Invariance Theorem 38.3. Let $f_0, f_1 \colon M \to N$ be maps between two closed oriented connected non-empty smooth manifolds of the same dimension. We assume that f_0 and f_1 are homotopic. Recall that we need to show that $\deg(f_0) = \deg(f_1)$. By the Whitney Approximation Theorem 29.1 we know that for $i = 0, 1$ the map f_i is homotopic to a smooth map $\widetilde{f}_i \colon M \to N$. Now we see that

$$\deg(f_0) \underset{\substack{\uparrow \\ \text{by definition}}}{=} \deg(\widetilde{f}_0) \underset{\substack{\uparrow \\ \text{by Proposition 38.2} \\ \text{applied to } g = f_0}}{=} \deg(\widetilde{f}_1) \underset{\substack{\uparrow \\ \text{by definition}}}{=} \deg(f_1).$$

■



Proof of the Degree Multiplicativity Theorem 38.4 if f and g are smooth. Let $f \colon L \to M$ and $g \colon M \to N$ be smooth maps between closed oriented connected non-empty smooth manifolds of the same dimension. We need to show that $\deg(g \circ f) = \deg(g) \cdot \deg(f)$. Evidently the plan is to apply Lemma 38.7, but to carry out this idea we need the following claim.

Claim. There exists a regular value z of $g \colon M \to N$ such that each point in $g^{-1}(z) \subset M$ is a regular value of $f \colon L \to M$.

Proof. We start out with some regular value z of $g \colon M \to N$. We denote the points in $g^{-1}(z)$ by $y_1, \dots, y_k \in M$. As in the proof of Lemma 38.5 we obtain from the Inverse Mapping Theorem 24.1 open neighborhoods $U_1, \dots, U_k$ of $y_1, \dots, y_k \in M$ such that each $g \colon U_k \to V_k := g(U_k)$ is a diffeomorphism. We set

$$W \;:=\; \Big(\bigcap_{i=1}^{k} V_i\Big) \setminus g\Big(M \setminus \bigcup_{i=1}^{k} U_i\Big) \;\subset\; N.$$

As in the proof of Lemma 38.5 we see that W is an open subset of N and that W contains z. For $i = 1, \dots, k$ we set $\widetilde{U}_i = U_i \cap g^{-1}(W)$ and we denote by C_i the set of regular values of f in $\widetilde{U}_i$. By Sard's Theorem 31.1 we know that the set of critical values of f has measure zero in M. It follows almost immediately, that each C_i is a set of full measure in the open subset $\widetilde{U}_i$ of M.

Since $g \colon \widetilde{U}_i \to W$ is a diffeomorphism we see that each $g(C_i)$ is also a set of full measure in W. It follows from the Full Measure-Density Proposition 30.3 that the set

$$\{\text{set of regular values of } g\} \;\cap W \;\cap \bigcap_{i=1}^{k} g(C_i)$$

is non-empty. Any point in this set has the desired property. ⊞

Now let $z \in N$ be a regular value of g such that each point in $g^{-1}(z)$ is a regular value of f. Then

$$\deg^z(g \circ f) \underset{\substack{\uparrow \\ \text{by Lemma 38.7}}}{=} \sum_{y \in g^{-1}(z)} \deg(g, y) \cdot \underbrace{\deg^y(f)}_{=\deg(f)} = \deg(f) \cdot \underbrace{\sum_{y \in g^{-1}(z)} \deg(g, y)}_{=\deg(g)} = \deg(f) \cdot \deg(g).$$

■

Proof of the Degree Multiplicativity Theorem 38.4. Let $f\colon L \to M$ and $g\colon M \to N$ be maps between closed oriented connected non-empty smooth manifolds of the same dimension. By the Whitney Approximation Theorem 29.1 we know that there exists a homotopy $F\colon L \times [0,1] \to M$ with $F_0 = f$ and such that $\widetilde{f} := F_1$ is smooth. Furthermore we know that there exists a homotopy $G\colon M \times [0,1] \to N$ with $G_0 = g$ and such that $\widetilde{g} := G_1$ is smooth. Note that the map

$$\begin{array}{rccl} G \circ (F \times \mathrm{id}_{[0,1]})\colon L \times [0,1] & \to & N \\ (x,t) & \mapsto & G(F(x,t),t) \end{array}$$

is a homotopy from $g \circ f$ to the smooth map $\widetilde{g} \circ \widetilde{f}$. Thus we see that

$$\deg(g \circ f) \underset{\substack{\uparrow \\ \text{by the above and the definition} \\ \text{of the degree of } g \circ f}}{=} \deg(\widetilde{g} \circ \widetilde{f}) \underset{\substack{\uparrow \\ \text{by the previous discussion} \\ \text{of the smooth case}}}{=} \deg(\widetilde{g}) \cdot \deg(\widetilde{f}) \underset{\substack{\uparrow \\ \text{by definition of the} \\ \text{degrees of } g \text{ and } f}}{=} \deg(g) \cdot \deg(f).$$

■

38.3. **Calculations of the degree.** First we state a few basic properties of the degree.

Lemma 38.8. (Basics of Degree Lemma) Let $f\colon M \to N$ be a smooth map between two closed oriented connected non-empty smooth manifolds of the same dimension.

(1) If f is not surjective, then $\deg(f) = 0$.
(2) If f is an orientation-preserving diffeomorphism, then $\deg(f) = 1$.
(3) If f is an orientation-reversing diffeomorphism, then $\deg(f) = -1$.

Proof.

(1) If $f\colon M \to N$ is not surjective, then we pick $z \in N \setminus f(M)$. Note that z is a regular value, and if we use this regular value for the calculation of $\deg(f)$, then we obtain immediately that $\deg(f) = 0$.
(2),(3) If $f\colon M \to N$ is a diffeomorphism, then every point in N is a regular value. The desired statements now follow from the Basics-of-Orientations Lemma 25.13. ■

Example. Let $A \in \mathrm{O}(n+1)$. In Exercise 25.5 we showed that the map $S^n \to S^n$ given by $x \mapsto A \cdot x$ is orientation-preserving if and only if $\det(A) = 1$. Combining this piece of information with the Basics of Degree Lemma 38.8 we see that

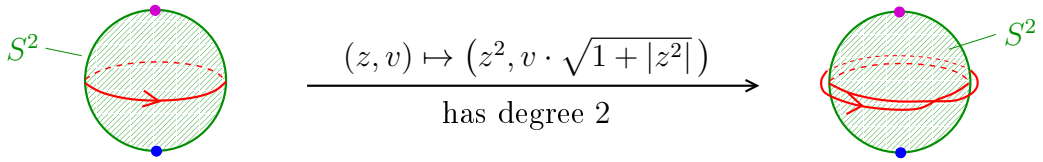
$$\deg\begin{pmatrix} S^n & \to & S^n \\ v & \mapsto & A \cdot v \end{pmatrix} = \det(A).$$

In particular, for $A = -\mathrm{id}_{n+1}$ we obtain that

$$\deg\left(\text{antipodal map } \begin{array}{ccc} S^n & \to & S^n \\ v & \mapsto & -v \end{array}\right) = \det(-\mathrm{id}_{n+1}) = (-1)^{n+1}.$$

The following lemma doubles as an interesting example of a calculation of the degree.

Lemma 38.9.



(1) Given any $d \in \mathbb{Z}$ we have

$$\deg\begin{pmatrix} S^1 & \to & S^1 \\ z & \mapsto & z^d \end{pmatrix} = d.$$

(2) Let $n \in \mathbb{N}$. We think of S^n as a subspace of $\mathbb{C} \times \mathbb{R}^{n-1}$. Given any $d \in \mathbb{N}$ we have[379]

$$\deg \begin{pmatrix} S^n & \to & S^n \\ (z,v) & \mapsto & \left(z^d, v \cdot \sqrt{1+|z^2|+\cdots+|z^2|^{d-1}}\right) \end{pmatrix} \;=\; d.$$

(3) Given any $n \in \mathbb{N}$ and given any $d \in \mathbb{Z}$ there exists a map $f\colon S^n \to S^n$ with degree $\deg(f) = d$.

Proof.

(1) The case $d = 0$ follows immediately from the Basics of Degree Lemma 38.8. Now assume that $d \neq 0$. In this case a straightforward calculation shows that each $x \in S^1$ is a regular point, thus every $y \in S^n$ is a regular value. We take $y = 1 \in S^1 \subset \mathbb{C}$ and we calculate

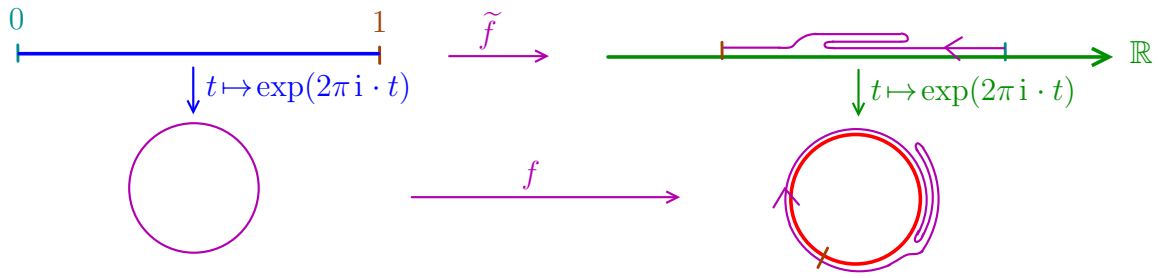
$$\deg(f) \;=\; \sum_{k=1}^{|d|} \deg(f, \exp(2\pi \mathrm{i} k/|d|)) \;=\; \sum_{k=1}^{|d|} \begin{cases} +1, & \text{if } d \geq 1, \\ -1, & \text{if } d < 1 \end{cases} \;=\; d.$$

using the Orientation Checking-via-Differentials Lemma 25.12 the orientation behavior can be deduced easily for the obvious extension of f to $\overline{B}^2$, the statement regarding S^1 then follows from the Boundary Orientation Lemma 25.17

(2) The proof of (2) is almost identical to the proof of (1). We leave it to the reader to fill in the details.

(3) Let $n \in \mathbb{N}$. The case $d > 0$ follows from (2). The case $d = -1$ follows from the example preceding the lemma which says in particular that any reflection in a hyperplane has degree -1. The case $d < 0$ follows from (2), the case $d = -1$ and the Degree Multiplicativity Theorem 38.4. Finally, by the Basics of Degree Lemma 38.8, the case $d = 0$ follows from taking a constant map $S^n \to S^n$. ∎

The following lemma often can be used to determine the degree of a self-map of S^1. The lemma will come in handy in the proof of the Whitney-Graustein Theorem 41.7.



Lemma 38.10. (Degree-via-Lifts Lemma) Let $f\colon S^1 \to S^1$ be a smooth map. If $\widetilde{f}\colon [0,1] \to \mathbb{R}$ is a continuous map such that for every $t \in [0,1]$ we have the equality[380] $f(\exp(2\pi \mathrm{i} \cdot t)) = \exp(2\pi \mathrm{i} \cdot \widetilde{f}(t))$, then

$$\deg(f\colon S^1 \to S^1) \;=\; \widetilde{f}(1) - \widetilde{f}(0).$$

[379] Let $d \in \mathbb{N}$ and let $(z,v) \in S^n$. Note that $\left(z^d, v \cdot \sqrt{1+|z^2|+\cdots+|z^2|^{d-1}}\right)$ does indeed lie in S^n. If $|z| = 1$, then $v = 0$, and in this case clearly $(z^d, 0) \in S^n$. Now assume that $|z| \neq 1$. From $(z,v) \in S^n$ it follows that $|z|^2 + \|v\|^2 = 1$, i.e. $1 - |z^2| = 1 - |z|^2 = \|v\|^2$. Thus we see that

$$|z^d|^2 + \left(\|v\| \cdot \sqrt{1+|z^2|+\cdots+|z^2|^{d-1}}\right)^2 \;=\; |z^2|^d + \|v\|^2 \cdot \frac{1-|z^2|^d}{1-|z^2|} \;=\; |z^2|^d + \|v\|^2 \cdot \frac{1-|z^2|^d}{\|v\|^2} \;=\; 1.$$

[380] In Lemma 34.8 we showed that such a map $\widetilde{f}$ always exists.

Example. Let $n \in \mathbb{Z}$. We consider the map $f\colon S^1 \to S^1$ that is given by $f(z) = z^n$. In this case $\widetilde{f}(t) = n \cdot t$ satisfies the conditions of the Degree-via-Lifts Lemma 38.10. Thus we see, once again, that $\deg(f) = \widetilde{f}(1) - \widetilde{f}(0) = n$.

Proof. We consider the maps

$$\begin{array}{rcl} \Phi\colon [0,1] & \to & S^1 \\ t & \mapsto & \exp(2\pi\mathrm{i}\cdot t) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Theta\colon \mathbb{R} & \to & S^1 \\ t & \mapsto & \exp(2\pi\mathrm{i}\cdot t). \end{array}$$

Let $f\colon S^1 \to S^1$ be a smooth map and let $\widetilde{f}\colon [0,1] \to \mathbb{R}$ be a map such that for any $t \in [0,1]$ we have $f(\exp(2\pi\mathrm{i}\cdot t)) = \exp(2\pi\mathrm{i}\cdot \widetilde{f}(t))$. In other words, we have $f \circ \Phi = \Theta \circ \widetilde{f}$, i.e. we have the following commutative diagram:

$$\begin{array}{ccc} [0,1] & \xrightarrow{\widetilde{f}} & \mathbb{R} \\ \downarrow{\scriptstyle \Phi} & & \downarrow{\scriptstyle \Theta} \\ S^1 & \xrightarrow{f} & S^1. \end{array}$$

Recall that by Lemma 34.7 we know that Θ is a local diffeomorphism. It follows, as in Lemma 34.8, that $\widetilde{f}$ is also smooth.

By Sard's Theorem 31.1 there exists a regular value $y \in S^1 \setminus \{(\Phi \circ f)(0)\}$ of $f\colon S^1 \to S^1$. We denote the preimages of y by $x_1, \dots, x_m \in S^1$. We denote by $t_1, \dots, t_m$ the unique real numbers in $(0,1)$ with $x_i = \Phi(t_i)$. After reordering them we can assume that $t_1 < \dots < t_m$. We pick $\widetilde{y} \in \mathbb{R}$ with $\Theta(\widetilde{y}) = y$.

We make the following observations:

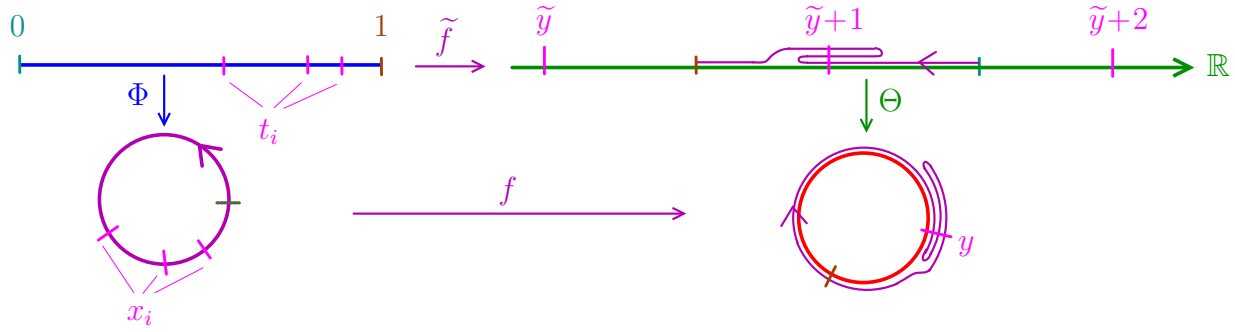
(1) We equip $[0,1]$, S^1 and $\mathbb{R}$ with the standard orientations. Let $i \in \{1, \dots, m\}$. Note that $\Phi\colon [0,1] \to S^1$ and $\Theta\colon \mathbb{R} \to S^1$ are orientation-preserving. It follows from $f \circ \Phi = \Theta \circ \widetilde{f}$ that $\widetilde{f}$ is orientation-preserving at t_i if and only if f is orientation-preserving at x_i. This implies that

$$\text{sign of } \underbrace{\widetilde{f}'(t_i)}_{\text{derivative of } \widetilde{f}} = \deg(f, x_i) \in \{-1, 1\}.$$

(2)
- As $\widetilde{f}([0,t_1)) \in S^1 \setminus \{y\}$ there is a unique $k_0 \in \mathbb{Z}$ with $\widetilde{f}([0,t_1)) \subset (\widetilde{y}+k_0, \widetilde{y}+k_0+1)$.
- Let $i \in \{1, \dots, m\}$. Since $\widetilde{f}((t_i, t_{i+1})) \in S^1 \setminus \{y\}$ there exists a unique $k_i \in \mathbb{Z}$ such that $\widetilde{f}((t_i, t_{i+1})) \subset (\widetilde{y}+k_i, \widetilde{y}+k_i+1)$.
- Finally, since $\widetilde{f}((t_{m-1}, 1]) \in S^1 \setminus \{y\}$ there exists a unique $k_m \in \mathbb{Z}$ such that $\widetilde{f}((t_m, 1]) \subset (\widetilde{y}+k_m, \widetilde{y}+k_m+1)$.

(3) It follows from (1) that for $i = 0, \dots, m-1$ we have $k_{i+1} = k_i + \deg(f, x_i)$.

Now we see that



$$\widetilde{f}(1) - \widetilde{f}(0) \underset{\uparrow}{=} k_m - k_0 = \sum_{i=0}^{m-1} (k_{i+1} - k_i) \underset{\uparrow}{=} \sum_{i=0}^{m-1} \deg(f, x_i) \underset{\uparrow}{=} \deg(f\colon S^1 \to S^1).$$

since $\widetilde{f}(1) \in (\widetilde{y} + k_m, \widetilde{y} + k_m + 1)$ and since $\widetilde{f}(0) \in (\widetilde{y} + k_0, \widetilde{y} + k_0 + 1)$ we see that $\widetilde{f}(1) - \widetilde{f}(0) \in (k_m - k_0 - 1, k_m - k_0 + 1)$, the equality then follows from the fact that $\widetilde{f}(1) - \widetilde{f}(0) \in \mathbb{Z}$

by (3)

by the definition of $\deg(f\colon S^1 \to S^1)$ on page 899

We heave thus proved the desired equality. ■

38.4. **Applications of the degree.**

Theorem 38.11. (Sphere-Degree Fixed Point Theorem) Let $n \in \mathbb{N}$. Every map $f\colon S^n \to S^n$ with $\deg(f) \neq (-1)^{n+1}$ has a fixed point.

Example. The Sphere-Degree Fixed Point Theorem Theorem 38.11 says in particular that every map $f\colon S^2 \to S^2$ of degree one has a fixed point. Together with the Degree Homotopy Invariance Theorem 38.3 this implies that every map $f\colon S^2 \to S^2$ that is homotopic to the identity has a fixed point. This means that we cannot "deform" the identity to a map that is fixed point free. This is in contrast to the case $n = 1$ where we can "deform" the identity into the map that is given by rotation by a small angle, which is of course a fixed point free map.

Proof. Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a map without fixed points. We need to show that $\deg(f) = (-1)^{n+1}$. The fact that f has no fixed points means by definition that for all $x \in S^n$ we have $f(x) \neq x$. It follows implies that for all $t \in [0,1]$ and all $x \in S^n$ we have[381] $(1-t) \cdot f(x) \neq t \cdot x$. Therefore we can consider the map

$$\begin{aligned} F\colon S^n \times [0,1] &\to S^n \\ (x,t) &\mapsto \frac{(1-t)\cdot f(x) - t \cdot x}{\|(1-t)\cdot f(x) - t \cdot x\|}. \end{aligned}$$

This map is a homotopy between the map $x \mapsto f(x)$ and the antipodal map $x \mapsto -x$. We obtain that

$$\deg(f) \underset{\uparrow}{=} \deg(\text{antipodal map } x \mapsto -x) \underset{\uparrow}{=} (-1)^{n+1}.$$

by the Degree Homotopy Invariance Theorem 38.3

see page 905

[381] we know that the degree is preserved under homotopies

This case be seen as follows: if $t \neq \frac{1}{2}$ we have $\|(1-t)\cdot f(x)\| = 1 - t \neq t = \|tx\|$. On the other hand, for $t = \frac{1}{2}$ we have $(1-t)\cdot f(x) = \frac{1}{2} f(x) \neq \frac{1}{2} x = tx$.

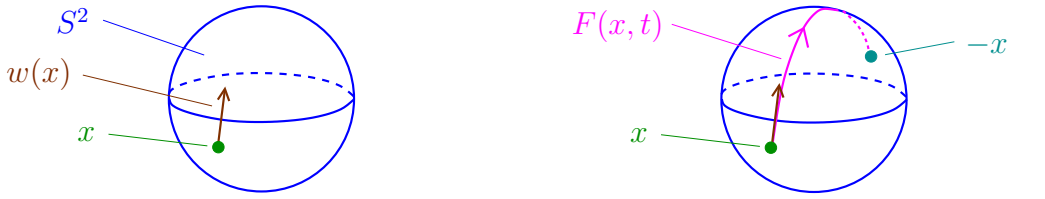
■

Next we turn to the study of vector fields on spheres. On page 638 we saw that every odd-dimensional sphere admits a nowhere-vanishing vector field. In Question 23.17 we asked whether it is possible to find a nowhere-vanishing vector field on even-dimensional spheres. The following proposition says that this is not possible.

Theorem 38.12. (Hairy Ball Theorem) Every vector field on an even-dimensional sphere S^{2k} vanishes on at least one point.[382]

Remark.

(1) We will discuss the Hairy Ball Theorem 38.12 again in somewhat greater detail on page 1690. At that point we will also give a different proof using homology groups.
(2) We will generalize the Hairy Ball Theorem 38.12 with the Smooth Poincaré–Hopf Theorem 45.17 and the Poincaré–Hopf Theorem 129.7.
(3) The literature contains many proofs of the Hairy Ball Theorem 38.12. Some, as our proofs, require some technology, some, see e.g. [**Miln1978**] get away with less technology. For the case of S^2 one can find especially short proofs, see e.g. [**EG1979, McG2016**].



Proof. Suppose S^n admits a nowhere-vanishing vector field v. We have to show that n is odd. We consider the vector field w on S^n that is given by rescaling v to length one, i.e. that is given by

$$\begin{array}{rcl} S^n & \to & \mathbb{R}^{n+1} \\ x & \mapsto & w(x) := \frac{1}{\|v(x)\|} \cdot v(x). \end{array}$$

Furthermore we consider the map

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \to & S^n \\ (x,t) & \mapsto & \cos(\pi t) \cdot x + \sin(\pi t) \cdot w(x). \end{array}$$

The map does indeed take values in S^n, since for any $x \in S^n$ and $t \in [0,1]$ we have

the vector field w gives rise to the homotopy F from id to $-$id

$$\begin{array}{rcl} \langle F(x,t), F(x,t)\rangle & = & \langle \cos(\pi t) \cdot x + \sin(\pi t) \cdot w(x), \cos(\pi t) \cdot x + \sin(\pi t) \cdot w(x)\rangle \\ & = & \cos(\pi t)^2 \cdot \|x\|^2 + \sin(\pi t)^2 \cdot \|w(x)\|^2 \;=\; 1. \\ & & \uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\ & & \text{since } \langle x, w(x)\rangle = 0 \qquad\qquad\qquad\qquad \text{since } \|x\| = \|w(x)\| = 1 \end{array}$$

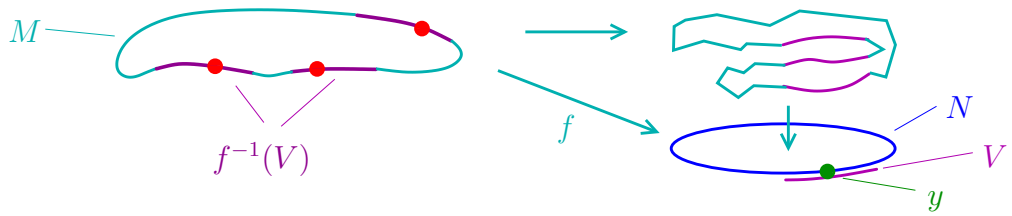
[382] On S^{2k} we had so far found vector fields which vanish at *two* points. Can we find a vector field on S^{2k} which vanishes on only *one* point? We will discuss this question in Exercise 76.6.

Note that the map F is a homotopy between the two maps $F_0 = \mathrm{id}$ and the antipodal map $F_1 = -\mathrm{id}$. It follows that

$$\begin{array}{ccccccc} 1 & \underset{\uparrow}{=} & \deg(\mathrm{id}_{S^n}) & \underset{\uparrow}{=} & \deg(-\mathrm{id}_{S^n}) & \underset{\uparrow}{=} & (-1)^{n+1}. \\ \text{Basics of Degree Lemma 38.8 (1)} & & & \text{by the Degree Homotopy Invariance Theorem 38.3 applied to the above homotopy} & & \text{see page 905} & \end{array}$$

But this means that n is odd. ■

38.5. **The Hopf Theorem.** Before we turn to the Hopf Theorem let us first show that given any closed oriented smooth manifold any integer can be realized as the degree of a map $M \to S^n$.



Proposition 38.13. (Degree Realization Proposition) Let $n \in \mathbb{N}$ and let M be a closed oriented connected non-empty n-dimensional smooth manifold. Given any $k \in \mathbb{Z}$ there exists a map $f\colon M \to S^n$ with $\deg(f) = k$.

Remark. We will reprove the Degree Realization Proposition 38.13 on page 2225.

The proof of the Degree Realization Proposition 38.13 rests on the following lemma which can be useful for calculating degrees of non-smooth maps.

Lemma 38.14. (Degree of Partially Smooth Map Lemma) Let $f\colon M \to N$ be a map between two closed oriented connected non-empty n-dimensional smooth manifolds. Let $y \in N$. Suppose that there exists an open neighborhood V of y such that f is smooth on $f^{-1}(V) \subset M$, such that $f^{-1}(y)$ consists of finitely many points and such that y is a regular value of the smooth map $f\colon f^{-1}(V) \to V$. Then

$$\deg(f) \;=\; \sum_{x \in f^{-1}(y)} \deg(f, x).$$

Proof of the Degree of Partially Smooth Map Lemma 38.14. The following claim is the key to proving the lemma.

Claim. The map f is homotopic to a smooth map g such that $f^{-1}(y) = g^{-1}(y)$ and such that for every $x \in f^{-1}(y)$ there exists an open neighborhood of x on which f and g agree.

Proof. We start out with a few preparations:

(a) We denote by $x_1, \ldots, x_m$ the points in $f^{-1}(y)$. For $i = 1, \ldots, m$ we pick a neighborhood U_i of x_i such that the closure $\overline{U}_i$ is contained in $f^{-1}(V)$.

(b) By the Manifold Metrization Proposition 18.10 or alternatively by the Manifold Metrization Proposition 27.4, we know that we can equip N with a metric d.

(c) Since M is compact and since $U_1, \dots, U_m$ are open we know by the Compact-Closed Lemma 1.21 and the Compact Image Lemma 2.13 that $f(M \setminus (U_1 \cup \dots \cup U_m))$ is a closed subset of N. Evidently $y \in f(M \setminus (U_1 \cup \dots \cup U_m))$.

(d) It follows from (b) and (c) together with the Distance-to-Subspace the Distance-to-Subspace Lemma 6.2 that there exists an $\epsilon > 0$ such that $d(f(x), y) > \epsilon$ for all $x \in M \setminus (U_1 \cup \dots \cup U_m)$.

It now follows from the Whitney Approximation Theorem 29.1 that there exists a homotopy $F\colon M \times [0,1] \to N$ with the following properties:

(1) We have $F_0 = f$.
(2) The map $F_1\colon M \to N$ is smooth.
(3) The homotopy is a homotopy rel $\overline{U}_1 \cup \dots \cup \overline{U}_m$.
(4) For every $(x, y) \in M \times [0,1]$ we have $d(F(x,t), f(x)) \leq \frac{\epsilon}{2}$.

We set $g = F_1$. By (2) the map g is smooth and by construction the map g is homotopic to f. It follows easily from (3) and (4) that $f^{-1}(y) = g^{-1}(y)$. Furthermore it follows from (3) and (4) that f and g agree on $(U_1 \cup \dots \cup U_m) \cap f^{-1}(B_{\frac{\epsilon}{2}}(y))$. Thus we see that for any $x \in f^{-1}(y)$ the maps f and g agree on the open neighborhood $(U_1 \cup \dots \cup U_m) \cap f^{-1}(B_{\frac{\epsilon}{2}}(y))$ of x. ⊞

Now we see that

$$\begin{array}{ccccccc} \deg(f) & = & \deg(g) & = & \displaystyle\sum_{x \in g^{-1}(y)} \deg(g, x) & = & \displaystyle\sum_{x \in f^{-1}(y)} \deg(f, x). \\ \uparrow & & & \uparrow & & \uparrow & \\ \text{by the Degree Homotopy} & & & \text{by design we know that } f^{-1}(y) = g^{-1}(y) \text{ and we know that} & & & \\ \text{Invariance Theorem 38.3} & & & \text{maps } f \text{ and } g \text{ agree on neighborhoods around each } x_i, & & & \\ & & & \text{in particular } y \text{ is also a regular value for } f \text{ and } g \text{ and} & & & \\ & & & \text{for each } x \in f^{-1}(y) \text{ we have } \deg(f,x) = \deg(g,x) & & & \end{array}$$

■

Proof of the Degree Realization Proposition 38.13. Let M be a closed oriented connected non-empty n-dimensional smooth manifold and let $k \in \mathbb{Z}$. By Lemma 38.9 there exists a map $g\colon S^n \to S^n$ of degree k. It follows from this fact and the Degree Multiplicativity Theorem 38.4 that it suffices to prove the following claim.

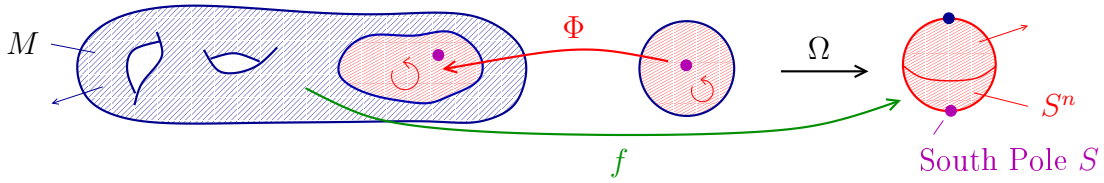
Claim. There exists a map $f\colon M \to S^n$ of degree $+1$.

Proof. Since M is non-empty we can pick an orientation-preserving smooth embedding $\Phi\colon \overline{B}^n \to M$. Next, similar to the setting of the Ball-Quotient Sphere Lemma 5.20 we consider the map

$$\begin{array}{rcl} \Omega\colon \overline{B}^n & \to & S^n \\ r \cdot v & \mapsto & \underbrace{\begin{pmatrix} 0 & (-1)^{n-1} & \dots \\ 0 & 0 & \mathrm{id}_{n-1} \\ -1 & \dots & 0 \end{pmatrix}}_{\in \mathrm{SO}(n+1)} \cdot \underbrace{\begin{pmatrix} \cos(\pi r) \\ \sin(\pi r) \cdot v \end{pmatrix}}_{\in \mathbb{R} \times \mathbb{R}^n = \mathbb{R}^{n+1}} \quad \text{with } r \in [0,1] \text{ and } v \in S^{n-1}. \end{array}$$

By the Ball-Quotient Sphere Lemma 5.20 this map has the following properties:

(1) The map Ω sends every point in S^{n-1} to the North Pole $N := (0, \dots, 0, 1)$.
(2) The map Ω sends the origin to the South Pole $S := (0, \dots, 0, -1)$.
(3) The map $B^n \to \overline{B}^n \xrightarrow{\Omega} S^n$ is a smooth embedding and, if we equip B^n and S^n with the standard orientations, the map is orientation-preserving.



Next we consider the map

$$\begin{array}{rcl} f\colon M & \to & S^n \\ x & \mapsto & \begin{cases} \Omega(\Phi^{-1}(x)), & \text{if } x \in \Phi(\overline{B}^n), \\ N, & \text{if } x \notin \Phi(\overline{B}^n). \end{cases} \end{array}$$

We make the following observations:

(1) It follows from the Compact Image Lemma 2.13, the Compact-Closed Lemma 1.21 (2) and the Pasting Pasting Proposition 2.6 (2) that f is continuous.
(2) The map f is smooth on the open subset $\Phi(B^n)$.
(3) Since Φ and $\Omega\colon B^n \to S^n$ are orientation-preserving smooth embeddings we see that the map $f|_{\Phi(B^n)}\colon \Phi(B^n) \to S^n$ is an orientation-preserving smooth embedding.

It follows from the Partially Smooth Map Lemma 38.14 applied to $y = S$ and $V = S^n \setminus \{N\}$ that $\deg(f) = 1$. ■

In the Degree Realization Proposition 38.13 we just showed that every closed orientable connected non-empty n-dimensional smooth manifold M admits a smooth map $f\colon M \to S^n$ of degree 1. In particular the torus $S^1 \times S^1$ admits a smooth map $f\colon S^1 \times S^1 \to S^2$ of degree 1. The question arises whether we can swap the roles of the torus and the sphere. In other words we have the following question.

Question 38.15. Does there exist a smooth map $f\colon S^2 \to S^1 \times S^1$ of degree one?

We will answer this question in Proposition **??** or alternatively Corollary 101.9, once we have developed many more tools.
Now we can finally state the Hopf Degree Theorem, which is the main theorem of this section. It gives a very satisfying classification of maps to S^n up to homotopy.

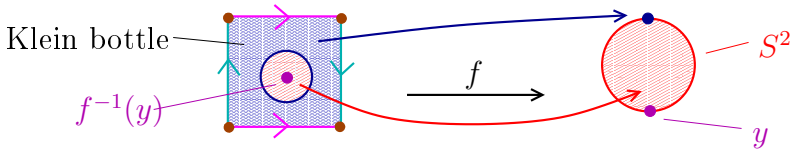
Theorem 38.16. (Hopf Degree Theorem) Let $n \in \mathbb{N}$, let M be a closed oriented connected non-empty n-dimensional smooth manifold and let $f, g\colon M \to S^n$ be two maps. Then

$$\deg(f) = \deg(g) \iff \text{the maps } f \text{ and } g \text{ are homotopic.}$$

Remark.

(1) For $n = 2$ the theorem was first proved by Luitzen Brouwer [**Brou1921**, p. 281], the general case was first proved by Heinz Hopf [**Hopf1927a**, Satz IIb].
(2) We will give an alternative proof of the Hopf Degree Theorem 38.16 much later later on page **??**, when we deduce it from the much more general Hopf Theorem **??**.
(3) The approach we use to prove the Hopf Degree Theorem 38.16 will also be used later in the proof of Proposition 157.10 where we calculate the cobordism group $\Omega_0^{\text{fat}}(\mathbb{R}^n)$.
(4) The reader who already knows about higher homotopy groups will have noticed that the Degree Realization Proposition 38.13 and the Hopf Degree Theorem 38.16, both applied to $M = S^n$, imply that $\pi_n(S^n) \cong \mathbb{Z}$.

Proof. We will prove the Hopf Degree Theorem 38.16 in the next and final section of this chapter. ■



We conclude this section with the non-orientable analogue of the Hopf Degree Theorem 38.16. To formulate this analogue we need to introduce the $\mathbb{Z}_2$-degree.

Definition. Let $f\colon M \to N$ be a map between two closed (possibly non-orientable) connected non-empty n-dimensional smooth manifolds. We do not assume that M or N are orientable. By the Whitney Approximation Theorem 29.1 we know that f is homotopic to a smooth map $g\colon M \to N$. Let $y \in N$ be a regular value of g. We define the $\mathbb{Z}_2$-degree of f as follows:

$$\deg_{\mathbb{Z}_2}(f) \;:=\; \#g^{-1}(y) \;\in\; \mathbb{Z}_2.$$

Using a variation on Proposition 38.2 one can show that this notion is well-defined.

One can easily show (see also Exercise 38.7) that the obvious analogues of Proposition 38.2, Theorem 38.1, the Degree Homotopy Invariance Theorem 38.3, the Degree Multiplicativity Theorem 38.4 and the Degree Realization Proposition 38.13 hold in this context. As an example we show in the figure a map $f\colon K \to S^2$ from the Klein bottle K to the sphere S^2 with $\deg_{\mathbb{Z}_2}(f) = 1 \in \mathbb{Z}_2$.

Now we can formulate the analogue of the Hopf Degree Theorem 38.16 for non-orientable manifolds.

Theorem 38.17. (Non-Orientable Hopf Degree Theorem) Let $n \in \mathbb{N}$ and let M be a closed *non-orientable* connected non-empty n-dimensional smooth manifold and let $f, g\colon M \to S^n$ be two maps. Then

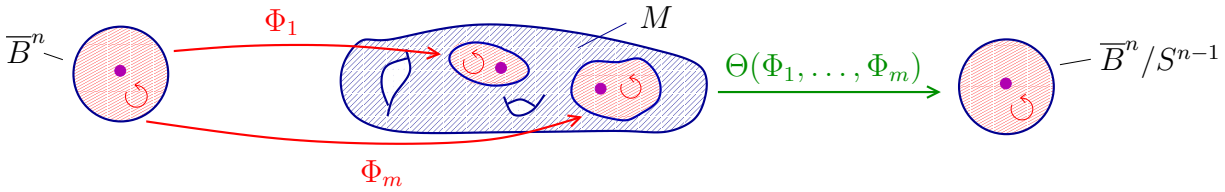
$$\deg_{\mathbb{Z}_2}(f) \;=\; \deg_{\mathbb{Z}_2}(g) \quad\Longleftrightarrow\quad \text{the maps } f \text{ and } g \text{ are homotopic.}$$

Proof. At the very end of this chapter we will explain how to modify the proof of the Hopf Degree Theorem 38.16 to obtain a proof of the Non-Orientable Hopf Degree Theorem 38.17. ■

38.6. **Proof of the Hopf Degree Theorem 38.16.** This final section is totally dedicated to the proofs of the Hopf Degree Theorem 38.16 and of the Non-Orientable Hopf Degree Theorem 38.17. First we recall and introduce some notation.

Notation. As in the Ball-Quotient Sphere Lemma 5.20 we consider the map

$$\begin{aligned} \Omega\colon \overline{B}^n/S^{n-1} &\to S^n \\ [r\cdot v] &\mapsto \underbrace{\begin{pmatrix} 0 & (-1)^{n-1} & \dots \\ 0 & 0 & \mathrm{id}_{n-1} \\ -1 & \dots & 0 \end{pmatrix}}_{\in \mathrm{SO}(n+1)} \cdot \underbrace{\begin{pmatrix} \cos(\pi r) \\ \sin(\pi r)\cdot v \end{pmatrix}}_{\in \mathbb{R}\times\mathbb{R}^n = \mathbb{R}^{n+1}} \quad \text{with } r \in [0,1] \text{ and } v \in S^{n-1}. \end{aligned}$$



By the Ball-Quotient Sphere Lemma 5.20 this map has the following properties:

(1) The map $\Omega\colon \overline{B}^n/S^{n-1} \to S^n$ is a homeomorphism. We use this homeomorphism and the usual smooth structure on S^n to equip $\overline{B}^n/S^{n-1}$ with a smooth structure and with an orientation.
(2) The map Ω sends the point $[S^{n-1}] \in \overline{B}^n/S^{n-1}$ to the North Pole $N := (0,\dots,0,1)$.
(3) The map Ω sends the origin to the South Pole $S := (0,\dots,0,-1)$.
(4) The map $B^n \to \overline{B}^n/S^{n-1} \xrightarrow{\Omega} S^n$ is an orientation-preserving smooth embedding.

Remark. We use the diffeomorphism $\Omega\colon \overline{B}^n/S^{n-1} \to S^n$ to replace in the following the smooth manifold S^n by $\overline{B}^n/S^{n-1}$. This approach greatly simplifies the notation throughout the following arguments.

Notation. Let M be a closed n-dimensional smooth manifold. Given smooth embeddings $\Phi_1,\dots,\Phi_m\colon \overline{B}^n \to M$ with disjoint images we define, similar to the construction in the proof of the Degree Realization Proposition 38.13, the map

$$\begin{array}{rccl} \Theta(\Phi_1,\dots,\Phi_m)\colon M & \to & \overline{B}^n/S^{n-1} & \\ x & \mapsto & \begin{cases} [\Phi_i^{-1}(x)], & \text{if } x \in \Phi_i(\overline{B}^n), \\ [S^{n-1}], & \text{otherwise.} \end{cases} \end{array}$$

The proof of the Hopf Degree Theorem 38.16 rests on three lemmas.

Lemma 38.18. Let M be a closed n-dimensional smooth manifold. Furthermore let $\Phi_1,\dots,\Phi_m\colon \overline{B}^n \to M$ be smooth embeddings with disjoint images.

(1) If M is oriented, then the degree of $\Theta(\Phi_1,\dots,\Phi_m)\colon M \to \overline{B}^n/S^{n-1}$ can be calculated as follows:

$$\Theta(\Phi_1,\dots,\Phi_m) \;=\; \sum_{i=1}^{m} \begin{cases} +1, & \text{if } \Phi_i \text{ is orientation-preserving,} \\ -1, & \text{if } \Phi_i \text{ is orientation-reversing.} \end{cases}$$

(2) Let $\Psi_1,\dots,\Psi_m\colon \overline{B}^n \to M$ be another set of smooth embeddings with disjoint images. If the smooth embedding[383] $\Phi_1 \sqcup \dots \sqcup \Phi_m\colon \overline{B}^n \sqcup \dots \sqcup \overline{B}^n \to M$ is smoothly isotopic to the smooth embedding $\Psi_1 \sqcup \dots \sqcup \Psi_m\colon \overline{B}^n \sqcup \dots \sqcup \overline{B}^n \to M$, then the maps $\Theta(\Phi_1,\dots,\Phi_m)\colon M \to \overline{B}^n/S^{n-1}$ and $\Theta(\Psi_1,\dots,\Psi_m)\colon M \to \overline{B}^n/S^{n-1}$ are homotopic.

Proof.

(1) The calculation of the degree follows from a slight variation on the argument of Proposition 38.13, using the general case of the Degree of Partially Smooth Map Lemma 38.14.

[383]Since the $\overline{B}^n$ is compact we obtain from Lemma 24.11 that m smooth embeddings of $\overline{B}^n$ with disjoint images give rise to a smooth embedding of the disjoint union of m closed balls.

(2) We start out with a few preparations:
   (a) By hypothesis we can pick a smooth isotopy $F\colon (\overline{B}^n \sqcup \cdots \sqcup \overline{B}^n) \times [0,1] \to M$ from the smooth embedding $\Phi_1 \sqcup \cdots \sqcup \Phi_m\colon \overline{B}^n \sqcup \cdots \sqcup \overline{B}^n \to M$ to the smooth embedding $\Psi_1 \sqcup \cdots \sqcup \Psi_m\colon \overline{B}^n \sqcup \cdots \sqcup \overline{B}^n \to M$.
   (b) We denote by $p\colon \overline{B}^n \times [0,1] \to \overline{B}^n$ and $q\colon \overline{B}^n \times [0,1] \to \overline{B}^n$ the projections.
   (c) Given $i = 1, \ldots, m$ we consider the map

$$\begin{aligned} \widetilde{F}_i = (F|_{\overline{B}_i \times [0,1]} \times q)\colon \overline{B}^n \times [0,1] &\to M \times [0,1] \\ (x,t) &\mapsto (F(x,t),t) \end{aligned}$$

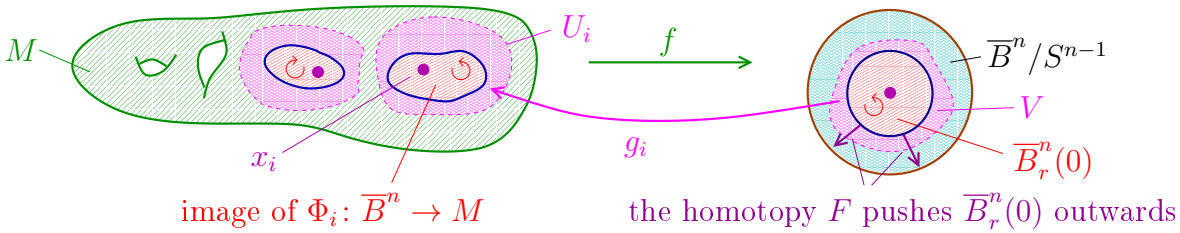
with x in the i-th copy of $\overline{B}^n$

   This map is injective and continuous. Since $\overline{B}^n \times [0,1]$ is compact and since $M \times [0,1]$ is Hausdorff it follows from the Compact-Hausdorff Proposition 2.17 (3) that it is an embedding. We denote by $\widetilde{F}_i^{-1}\colon \widetilde{F}_i(\overline{B}^n \times [0,1]) \to \overline{B}^n \times [0,1]$ the inverse.

Finally we consider the map

$$\begin{aligned} G\colon M \times [0,1] &\to \overline{B}^n/S^{n-1} \\ z &\mapsto \begin{cases} [p(\widetilde{F}_i^{-1}(z))], & \text{if } z \in \widetilde{F}_i(\overline{B}^n \times [0,1]), \\ [S^{n-1}], & \text{otherwise.} \end{cases} \end{aligned}$$

Basically by definition we have $G_0 = \Theta(\Phi_1, \ldots, \Phi_m)$ and $G_1 = \Theta(\Psi_1, \ldots, \Psi_m)$. Thus it remains to show that the map $G\colon M \times [0,1] \to \overline{B}^n/S^{n-1}$ is continuous. First note that it follows from the Codimension-Zero Smooth Embedding Proposition 24.16 that $\widetilde{F}_1(B^n \times [0,1]) \cup \cdots \cup \widetilde{F}_m(B^n \times [0,1])$ is an open subset of $M \times [0,1]$. Furthermore it follows from the Product Topology Properties Proposition 5.6, the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 (2) that $\widetilde{F}_1(\overline{B}^n \times [0,1]) \cup \cdots \cup \widetilde{F}_1(\overline{B}^n \times [0,1])$ is a closed subset of $M \times [0,1]$. It follows from this lengthy discussion and the Pasting Pasting Proposition 2.6 (2) that this map $M \times [0,1] \to \overline{B}^n/S^{n-1}$ is indeed continuous. ■



Lemma 38.19. Let M be a closed n-dimensional smooth manifold. Given any map $f\colon M \to \overline{B}^n/S^{n-1}$ there exist smooth embeddings $\Phi_1, \ldots, \Phi_m\colon \overline{B}^n \to M$ with disjoint images such that f is homotopic to $\Theta(\Phi_1, \ldots, \Phi_m)\colon M \to \overline{B}^n/S^{n-1}$.

Proof of Lemma 38.19. We start out with the following straightforward steps:

(1) By the Whitney Approximation Theorem 29.1 and the Degree Homotopy Invariance Theorem 38.3 we can assume that f is smooth.
(2) By Sard's Theorem 31.1 we know that the smooth map $f\colon M \to \overline{B}^n/S^{n-1}$ has a regular value. By applying the Homogeneous-via-Diffeotopies Proposition 33.14 to the smooth manifold $\overline{B}^n/S^{n-1}$ we can assume that the "origin" $0 \in \overline{B}^n/S^{n-1}$ is a regular value of f.
(3) We denote the preimages of 0 by $x_1, \ldots, x_m \in M$.
(4) Since each $\mathrm{D}f_{x_i}\colon \mathrm{T}_{x_i}M \to \mathrm{T}_0\overline{B}^n/S^{n-1}$ is an isomorphism we know by the Inverse Mapping Theorem 24.1 that there exist neighborhoods $U_1, \ldots, U_m$ of $x_1, \ldots, x_m$ and V of $0 \in \overline{B}^n/S^{n-1}$ such that for each $i \in \{1, \ldots, m\}$ the map f restricts to a diffeomorphism $f\colon U_i \to V$.

(5) Since M is Hausdorff we can arrange that the neighborhoods $U_1, \dots, U_m$ of $x_1, \dots, x_m$ are disjoint.
(6) For $i = 1, \dots, m$ we denote by $g_i \colon V \to U_i$ the inverse of $f \colon U_i \to V$.
(7) We pick an $r \in (0,1)$ such that $\overline{B}^n_r(0) \subset V$.
(8) For $i = 1, \dots, m$ we consider the smooth embedding

$$\begin{array}{rcl} \Phi_i \colon \overline{B}^n & \to & M \\ x & \mapsto & g_i(x \cdot r). \end{array}$$

It now remains to prove the following claim.

Claim. The map $f \colon M \to \overline{B}^n/S^{n-1}$ is homotopic to $\Theta(\Phi_1, \dots, \Phi_m) \colon M \to \overline{B}^n/S^{n-1}$.

Proof. We consider the homotopy[384]

$$\begin{array}{rcl} F \colon \overline{B}^n/S^{n-1} \times [0,1] & \to & \overline{B}^n/S^{n-1} \\ ([x],t) & \mapsto & \begin{cases} [x \cdot ((1-t) + t \cdot \frac{1}{r})], & \text{if } \|x\| \le r, \\ [x \cdot ((1-t) + t \cdot \frac{1}{\|x\|})], & \text{if } \|x\| \ge r \end{cases} \end{array}$$

from $F_0 = \mathrm{id}$ to a map $F_1 \colon \overline{B}^n/S^{n-1} \to \overline{B}^n/S^{n-1}$ whose restriction to $\overline{B}^n_r(0)$ is induced by multiplication by $\frac{1}{r}$. Intuitively this homotopy F "expands" the r-ball till it covers all of the sphere $\overline{B}^n/S^{n-1}$ and everything outside of the r-ball gets pushed to the point $[S^{n-1}]$.

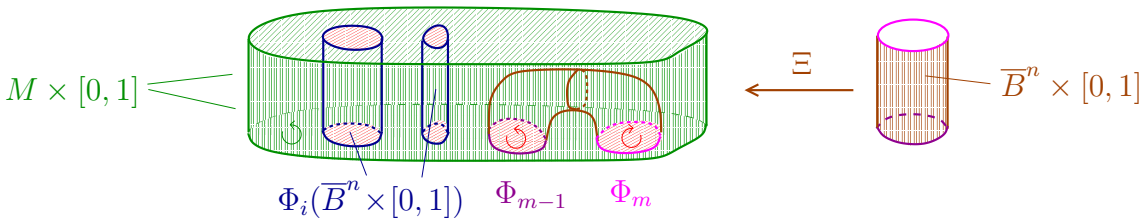
Finally note that it follows immediately from the definitions that the map

$$\begin{array}{rcl} G = F \circ (f \times (\text{projection to } [0,1])) \colon M \times [0,1] & \to & \overline{B}^n/S^{n-1} \\ (x,t) & \mapsto & F(f(x),t) \end{array}$$

is a homotopy from f to $\Theta(\Phi_1, \dots, \Phi_m)$. ∎

Our next lemma is a refinement of the previous Lemma 38.19. The proof of the next lemma contains perhaps the most clever idea in the context of the proof of the Hopf Degree Theorem 38.16.

Lemma 38.20. Let M be a closed oriented n-dimensional smooth manifold. Furthermore let $f \colon M \to \overline{B}^n/S^{n-1}$ be a map. We set $k := |\deg(f)|$. There exist k smooth embeddings $\Phi_1, \dots, \Phi_k \colon \overline{B}^n \to M$ with disjoint images such that the map $f \colon M \to \overline{B}^n/S^{n-1}$ is homotopic to $\Theta(\Phi_1, \dots, \Phi_k) \colon M \to \overline{B}^n/S^{n-1}$.



[384] To show that the map is continuous actually requires a bit of footwork. First note that it follows from the Pasting Proposition 2.6 that the obvious corresponding map $\overline{B}^n \times [0,1] \to \overline{B}^n$ is continuous. By the Twice Quotient Lemma 5.23 this map descends to a continuous map $(\overline{B}^n \times [0,1])/\sim \to \overline{B}^n/S^{n-1}$. Finally it follows from the subtle the Product-Quotient Mixing Lemma 13.6 that the given map $\overline{B}^n/S^{n-1} \times [0,1] \to \overline{B}^n/S^{n-1}$ is also continuous.

Proof of Lemma 38.20. Let M be a closed oriented n-dimensional smooth manifold and let $f\colon M \to \overline{B}^n/S^{n-1}$ be a map of degree k. By Lemma 38.19 we know that there exist smooth embeddings $\Phi_1, \dots, \Phi_m\colon \overline{B}^n \to M$ with disjoint images such that f is homotopic to $\Theta(\Phi_1, \dots, \Phi_m)\colon M \to \overline{B}^n/S^{n-1}$.

It follows from Lemma 38.18 (1) that $m \geq k$. If $m = k$, then we are done. Now assume that $m > k$. It follows again from Lemma 38.18 (1) that, after possibly reordering the Φ_i, we can assume that the smooth embedding $\Phi_{m-1}\colon \overline{B}^n \to M$ is orientation-preserving and that the smooth embedding $\Phi_m\colon \overline{B}^n \to M$ is orientation-reversing. By induction on m it suffices to show that $\Theta(\Phi_1, \dots, \Phi_m)$ is homotopic to $\Theta(\Phi_1, \dots, \Phi_{m-2})$.

Claim. There exists a smooth embedding $\Xi\colon \overline{B}^n \times [0,1] \to M \times [0,1)$ with the following two properties:

(1) For every $x \in \overline{B}^n$ we have $\Xi(x,0) = (\Psi_{m-1}(x), 0)$ and $\Xi(x,1) = (\Psi_m(x), 0)$.
(2) The image of Ξ is disjoint from $\Phi_i(\overline{B}^n) \times [0,1]$, $i = 1, \dots, m-2$.

Proof. It follows fairly easily from the Smooth Ball Embedding Theorem 37.8 that there exists an open subset $U \subset M$ and an orientation-preserving chart $\Gamma\colon U \to B^n_6(0)$ with the following properties:

(1) $\Phi_1(\overline{B}^n) \cup \dots \cup \Phi_m(\overline{B}^n)$ are contained in U,
(2) $\Gamma(\Phi_1(\overline{B}^n)) \cup \dots \cup \Gamma(\Phi_{m-2}(\overline{B}^n))$ is contained in $B^n_6(0) \setminus B^n_4(0)$,
(3) $\Gamma \circ \Phi_{m-1}\colon \overline{B}^n \to B^n_6(0)$ is given by $(x_1, \dots, x_n) \mapsto (-2 + x_1, x_2, \dots, x_n)$.
(4) $\Gamma \circ \Phi_m\colon \overline{B}^n \to B^n_6(0)$ is given by $(x_1, \dots, x_n) \mapsto (2 - x_1, x_2, \dots, x_n)$.

The desired smooth embedding is now given by

$$\begin{array}{rcl} \Xi\colon \overline{B}^n \times [0,1] & \to & M \times [0,1] \\ (x_1, x_2, \dots, x_n, t) & \mapsto & \Gamma^{-1}(\cos(\pi \cdot t) \cdot (-2 + x_1), x_2, \dots, x_n, \underbrace{\tfrac{1}{2}\sin(\pi \cdot t) \cdot x_1}_{\in [0,1)}). \end{array}$$

⊞

In the following we will use the smooth embedding $\Xi\colon \overline{B}^n \times [0,1] \to M \times [0,1]$ to construct a homotopy from $\Theta(\Phi_1, \dots, \Phi_m)$ to $\Theta(\Phi_1, \dots, \Phi_{m-2})$. To do so we need to make a few preparations:

(1) For $i = 1, \dots, m-2$ we denote by $\widetilde{F}_i\colon \overline{B}^n \times [0,1] \to M \times [0,1]$ the embedding that is given by $\widetilde{F}_i(x,t) = (\Phi_i(x), t)$.
(2) We denote by $p\colon \overline{B}^n \times [0,1] \to \overline{B}^n$ the projection.

Similar to the proof of Lemma 38.18 we now consider the map

$$\begin{array}{rcl} G\colon M\times[0,1] & \to & \overline{B}^n/S^{n-1} \\ z & \mapsto & \begin{cases} p(\widetilde{F}_i^{-1}(z)), & \text{if } z\in \widetilde{F}_i(\overline{B}^n\times[0,1]), \\ p(\Xi^{-1}(z)), & \text{if } z\in \Xi(\overline{B}^n\times[0,1]), \\ [S^{n-1}], & \text{otherwise.} \end{cases} \end{array}$$

The argument in the proof of Lemma 38.18 shows that $G\colon M\times[0,1]\to\overline{B}^n/S^{n-1}$ is continuous, i.e. G is a homotopy. Finally note that it follows immediately from the definitions that $G_0=\Theta(\Phi_1,\dots,\Phi_m)$ and $G_1=\Theta(\Phi_1,\dots,\Phi_{m-2})$. ■

Proof of the Hopf Degree Theorem 38.16. Let $n\in\mathbb{N}$ and let M be a closed oriented connected non-empty n-dimensional smooth manifold. As we discussed on page 913, the smooth manifold M admits an orientation-preserving diffeomorphism to $\overline{B}^n/S^{n-1}$. Thus it suffices to prove the following claim.

Claim. Given any two maps $f,g\colon M\to\overline{B}^n/S^{n-1}$ we have

$$\deg(f)=\deg(g) \quad\Longleftrightarrow\quad \text{the maps } f \text{ and } g \text{ are homotopic.}$$

Proof. The "$\Leftarrow$"-direction is just a special case of the Degree Homotopy Invariance Theorem 38.3. We turn to the proof of the "$\Rightarrow$"-direction. We set $k:=|\deg(f)|=|\deg(g)|$.

First we point out that by Lemma 38.20 we know that there exist smooth embeddings $\Phi_1,\dots,\Phi_k\colon\overline{B}^n\to M$ with disjoint images such that $f\colon M\to\overline{B}^n/S^{n-1}$ is homotopic to $\Theta(\Phi_1,\dots,\Phi_k)\colon M\to\overline{B}^n/S^{n-1}$. The same way we also see that there exist smooth embeddings $\Psi_1,\dots,\Psi_k\colon\overline{B}^n\to M$ with disjoint images such that $g\colon M\to\overline{B}^n/S^{n-1}$ is homotopic to $\Theta(\Psi_1,\dots,\Psi_k)\colon M\to\overline{B}^n/S^{n-1}$.

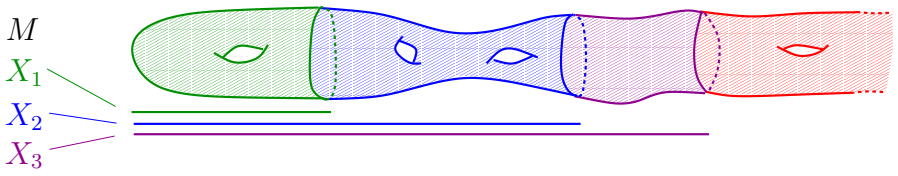
We now assume that $\deg(f)=\deg(g)\geq 0$. Note that in this case it follows immediately from $k=\deg(f)=\deg(g)$ and Lemma 38.18 (1) that all of the smooth embeddings $\Phi_1,\dots,\Phi_k\colon\overline{B}^n\to M$ and $\Psi_1,\dots,\Psi_k\colon\overline{B}^n\to M$ are orientation-preserving. Thus it follows from the Smooth Ball Embedding Theorem 37.8 that there exists a smooth isotopy between $\Phi_1\sqcup\dots\sqcup\Phi_k\colon\overline{B}^n\sqcup\dots\sqcup\overline{B}^n\to M$ and $\Psi_1\sqcup\dots\sqcup\Psi_k\colon\overline{B}^n\sqcup\dots\sqcup\overline{B}^n\to M$. By Lemma 38.18 (2) this implies that $\Theta(\Phi_1,\dots,\Phi_k)\colon M\to\overline{B}^n/S^{n-1}$ and $\Theta(\Psi_1,\dots,\Psi_k)\colon M\to\overline{B}^n/S^{n-1}$ are homotopic.

Finally we assume that $\deg(f)=\deg(g)<0$. In this case it follows immediately from $k=-\deg(f)=-\deg(g)$ and Lemma 38.18 (1) that all of the smooth embeddings $\Phi_1,\dots,\Phi_k\colon\overline{B}^n\to M$ and $\Psi_1,\dots,\Psi_k\colon\overline{B}^n\to M$ are orientation-reversing. The remainder of the argument is identical to the above. ■

Proof of the Non-Orientable Hopf Degree Theorem 38.17. The proof is almost entirely the same as the above proof of the Hopf Degree Theorem 38.17. The only real difference is that we have to reformulate Lemma 38.20 in the obvious way and in the proof of Lemma 38.20 we now apply the Smooth Ball Embedding Theorem 37.8 for non-orientable smooth manifolds. Note that in the non-orientable setting we do not have to distinguish between orientation-preserving and orientation-reversing smooth embeddings of balls. We leave it to the reader to fill in the details. ■

Exercises for Chapter 38.

Exercise 38.1. Let M be a connected orientable n-dimensional smooth manifold with *non-empty* boundary. We want to show that every map $f\colon M \to S^n$ is null-homotopic. There are various approaches to proving this result. One way is as follows:



(a) Pick a collar neighborhood $[0,1] \times \partial M$ and show that f is homotopic to a map $g\colon M \to S^n$ which has a regular value $y \in S^n$ such that $f^{-1}(y) \subset [0,1] \times \partial M$.
(b) Use (a) to show that f is homotopic to a map $M \to S^n$ that is not surjective.

Remark. A different approach is sketched in [**OR2009**, p. 193].

Exercise 38.2. Let M be a connected *non-compact* n-dimensional smooth manifold without boundary. We want to show that any map $f\colon M \to S^n$ is null-homotopic. There are various approaches to proving this result. One way is as follows:

(a) By the Compact Submanifold Exhaustion Proposition 31.2 we can pick an exhaustion of M by a sequence of $\{X_k\}_{k\in\mathbb{N}}$ of compact submanifolds.
(b) Use Exercise 38.1 to show that for each $k \in \mathbb{N}$ there exists a homotopy F^k rel $M \setminus X_{k+1}$ such that $F^k_1(X_k) = \{S\}$, where $S = (0,\dots,0,-1)$ is the "South Pole".
(c) Use the homotopies from (b) to define a homotopy $G\colon M \times [0,1] \to M$, where G is defined separately on the subsets $M \times [1 - \frac{1}{2^{k-1}}, 1 - \frac{1}{2^k}]$.

Remark. A different approach is sketched in [**OR2009**, p. 193].

Exercise 38.3. Let $f, g\colon S^n \to S^n$ be two maps. Show that $f \circ g$ and $g \circ f$ are homotopic.
Remark. In Exercise 38.5 we will see that the analogous statement is not true for the torus.

Exercise 38.4. Let $f, g\colon S^1 \to S^1$ be two maps. We consider the map

$$\begin{array}{rccc} f \cdot g\colon & S^1 & \to & S^1 \\ & z & \mapsto & f(z) \cdot g(z). \end{array}$$

Show that $\deg(f \cdot g) = \deg(f) + \deg(g)$.

Exercise 38.5. We consider the following maps

$$\begin{array}{cccc} i_1\colon S^1 \to S^1 \times S^1 & i_2\colon S^1 \to S^1 \times S^1 & p_1\colon S^1 \times S^1 \to S^1 & p_2\colon S^1 \times S^1 \to S^1 \\ z \mapsto (z,1) & z \mapsto (1,z) & (z_1,z_2) \mapsto z_1 & (z_1,z_2) \mapsto z_2. \end{array}$$

(a) Given a map $f\colon S^1 \times S^1 \to S^1 \times S^1$ we define

$$\Theta(f) \;:=\; \begin{pmatrix} \deg(p_1 \circ f \circ i_1) & \deg(p_1 \circ f \circ i_2) \\ \deg(p_2 \circ f \circ i_1) & \deg(p_2 \circ f \circ i_2) \end{pmatrix} \;\in\; \mathrm{M}(2 \times 2, \mathbb{Z}).$$

Show that for any two maps $f, g\colon S^1 \times S^1 \to S^1 \times S^1$ we have $\Theta(f \circ g) = \Theta(f) \cdot \Theta(g)$.
Hint. Use Exercise 38.4 and use that $\mathrm{id} = (p_1 \circ i_1) \cdot (p_2 \circ i_2)\colon S^1 \times S^1 \to S^1 \times S^1$.

(b) Show that there exist maps $f, g\colon S^1 \times S^1 \to S^1 \times S^1$ such that $f \circ g$ and $g \circ f$ are not homotopic.
Remark. This exercise shows that the conclusion of Exercise 38.3 does not hold for the torus.

Exercise 38.6. We defined the degree for a map $f\colon M \to N$ between two closed oriented connected smooth manifolds of the same dimension. We used that M is compact to argue that the degree is actually defined, i.e. given by a finite sum of ± 1. We did not really make use of the hypothesis that N is closed. In fact the same definition makes perfect sense if N is any smooth manifold with empty boundary. Show that if M is closed and N is non-compact, then for any smooth map $f\colon M \to N$ we have $\deg(f) = 0$.

Exercise 38.7. Let $f\colon M \to N$ be a map between two closed connected non-empty n-dimensional smooth manifolds. We do not assume that M or N are orientable. By the Whitney Approximation Theorem 29.1 we know that f is homotopic to a smooth map $g\colon M \to N$. Let $y \in N$ be a regular value of g. We define the $\mathbb{Z}_2$-*degree of* f as follows:

$$\deg_{\mathbb{Z}_2}(f) \;:=\; \#g^{-1}(y) \;\in\; \mathbb{Z}_2.$$

(a) Convince yourself that the obvious analogues of Proposition 38.2, Theorem 38.1, the Degree Homotopy Invariance Theorem 38.3 and the Degree Multiplicativity Theorem 38.4 hold in this context. Put differently, reread the proofs and make mentally the necessary adjustments for the present case.
(b) Does there exist a map f from the Klein bottle to the real projective plane $\mathbb{R}\mathrm{P}^2$ with $\deg_{\mathbb{Z}_2}(f) = 1$?

Exercise 38.8. What is the degree of the map

$$\begin{array}{rcl} f\colon \mathbb{C}\mathrm{P}^n & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 : \cdots : z_n] & \mapsto & [z_0^2 : \cdots : z_n^2]\,? \end{array}$$

Exercise 38.9.

(1) Let $g\colon S^n \to S^n$ be a smooth map with $g(-x) = g(x)$ for all $x \in S^n$. Show that $\deg(g)$ is even.
(2) Let $f\colon S^n \to S^n$ be a smooth map of odd degree. Show that there exists antipodal points $x, -x$ in S^n which get sent to antipodal points, i.e. $f(x) = -f(-x)$.
Hint. Let $f\colon S^n \to S^n$ be a map such that for each $x \in S^n$ we have $f(x) \neq -f(-x)$. Consider the homotopy

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \to & S^n \\ (x,t) & \mapsto & \dfrac{(1-\frac{1}{2}t)\cdot f(x) + \frac{1}{2}t \cdot f(-x)}{\|(1-\frac{1}{2}t)\cdot f(x) + \frac{1}{2}t \cdot f(-x)\|}. \end{array}$$

Exercise 38.10. Let $n \in \mathbb{N}$ be odd. Recall that by the Real Projective Space Orientability Lemma 25.21 we know that $\mathbb{R}\mathrm{P}^n$ is a closed orientable smooth manifold. Determine the degree of the orientation-preserving map $p\colon S^n \to \mathbb{R}\mathrm{P}^n$ that is given by $x \mapsto [x]$.

Exercise 38.11.

(a) Let $f\colon M \to N$ be a smooth map between two closed oriented connected non-empty n-dimensional smooth manifolds. Suppose that there exists a compact smooth manifold W with $\partial W = M$ and a smooth map $g\colon W \to N$ with $g|_M = f$. Show that

$\deg(f) = 0$.

Hint. Pick up some ideas from the proof of the Degree Homotopy Invariance Theorem 38.3.

(b) Use (a) to give a new proof of the Degree Homotopy Invariance Theorem 38.3.

Exercise 38.12. As in Lemma 2.18 we consider the stereographic projection from the North Pole $N := (0,0,1)$:

$$\begin{array}{rcl} \Phi\colon S^2 & \to & \mathbb{R}^2 \cup \{\infty\} = \mathbb{C} \cup \{\infty\} \\ (x_1,x_2,x_3) & \mapsto & \begin{cases} \left(\frac{x_1}{1-x_3}, \frac{x_2}{1-x_3}\right), & \text{if } x_3 \neq 1, \\ \infty, & \text{if } x_3 = 1. \end{cases} \end{array}$$

Now let $q(z) = a_0 + a_1 z + \cdots + a_n z^n$ be a polynomial with complex coefficients. We consider the map

$$\begin{array}{rcl} \Theta(q)\colon S^2 & \to & S^2 \\ P & \mapsto & \begin{cases} \Phi^{-1}(q(\Phi(P))), & \text{if } P \neq N, \\ N, & \text{if } P = N. \end{cases} \end{array}$$

(For the record we mention that on page 705 we showed that this map is smooth.)

(a) Suppose that $a_n \neq 0$. Show that the maps $\Theta(q)$ and $\Theta(z^n)$ are homotopic.

Remark. This exercise is almost identical to Exercise 14.9.

(b) Show that $\deg(\Theta(z^n)) = n$.

(c) Show that if $n \geq 1$ and $a_n \neq 0$, then $q(z)$ has at least one zero.

Remark. We have just provided another proof of the Fundamental Theorem of Algebra 26.3.

Exercise 38.13. Let $p(z)$ be a complex polynomial.

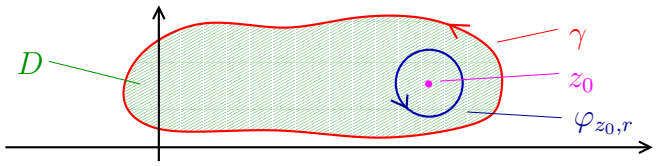
(a) Let $z_0 \in \mathbb{C}$ be a zero and let $r > 0$ such that z_0 is the only zero of $p(z)$ on $\overline{B}_r(z_0) \subset \mathbb{C}$. We consider the smooth map

$$\begin{array}{rcl} \varphi_{z_0,r}\colon S^1 & \to & S^1 \\ w & \mapsto & \dfrac{p(z_0 + r \cdot w)}{\|p(z_0 + r \cdot w)\|}. \end{array}$$

Show that

$$\deg(\varphi_{z_0,r}) \;=\; \text{order of the zero } z_0 \text{ of the polynomial } p(z).$$

(b) Let $D \subset \mathbb{C}$ be a compact codimension-zero submanifold such that there exists an orientation-preserving diffeomorphism $\gamma\colon S^1 \to \partial D$. We suppose that $p(z)$ does not have a zero on ∂D. Show that



$$\deg\left(\begin{array}{rcl} S^1 & \to & S^1 \\ w & \mapsto & \frac{p(\gamma(w))}{\|p(\gamma(w))\|} \end{array}\right) \;=\; \text{number of zeros of } p(z) \text{ in } D.$$

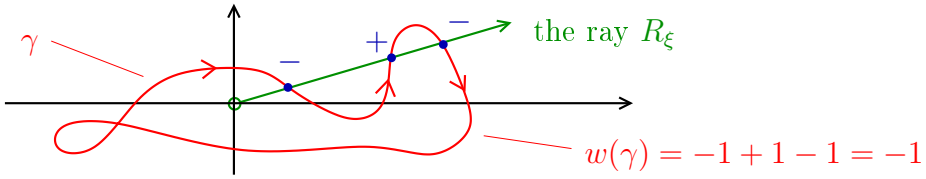
Hint. Pick disjoint disks around the zeros of $p(z)$ in D.

Remark. This statement is known as the *Argument Principle*.

(c) Use (b) to give one more proof of the Fundamental Theorem of Algebra.

Exercise 38.14. It is easy to come up with a self-map of S^2 with a self-homeomorphism of S^2 with two fixed points. Does there exist a self-homeomorphism of S^2 with precisely one fixed point?

Exercise 38.15. Given a smooth map $\gamma\colon S^1 \to \mathbb{C}\setminus\{0\}$ we define the *winding number*



$$\mathrm{w}(\gamma) \;:=\; \deg\begin{pmatrix} S^1 & \to & S^1 \\ z & \mapsto & \frac{\gamma(z)}{\|\gamma(z)\|} \end{pmatrix}.$$

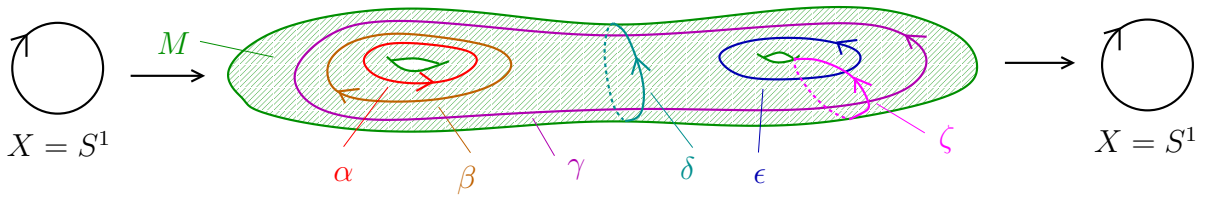
Let $\gamma\colon S^1 \to \mathbb{C}\setminus\{0\}$ be a smooth map. Given $\xi \in S^1$ we consider the corresponding ray $R_\xi := \{r\cdot\xi \,|\, r \in (0,\infty)\}$. We say γ intersects R_z transversally if for every $z \in S^1$ with $\gamma(z) \in R_\xi$ the vectors $\gamma'(z)$ and ξ are linearly independent. Given such a $z \in S^1$ we define

$$\mathrm{sign}(\gamma, z) \;=\; \begin{cases} +1, & \text{if } \xi, \gamma'(z) \text{ is a positive basis of } \mathbb{C} = \mathbb{R}^2, \\ -1, & \text{otherwise.} \end{cases}$$

Show that if γ intersects R_z transversally, then

$$\mathrm{w}(\gamma) \;=\; \sum_{z\in S^1 \text{ with } \gamma(z)\in R_\xi} \mathrm{sign}(\gamma, z).$$

Exercise 38.16. Given a smooth map $\gamma\colon S^1 \to \mathbb{C}\setminus\{0\}$ we denote by $\mathrm{w}(\gamma)$ the winding number that we introduced in Exercise 38.15. Suppose that at a time $t = 0$ a person starts walking around a tree and the person keeps a dog on a leash. At $t = 1$ both the person and the dog are precisely at the starting position. We suppose that at any moment the distance of the person to the tree is longer than the leash. Show that the person and the dog have the same winding number around the tree.
Remark. This statement is colloquially known as the *Dog Walking Theorem*.



Exercise 38.17. Let $f\colon A \to M$ and $g\colon B \to N$ be smooth maps between closed oriented connected non-empty smooth manifolds with $\dim(A) = \dim(M)$ and $\dim(B) = \dim(N)$. Show that

$$\deg(f\times g\colon A\times B \to M\times N) \;=\; \deg(f\colon A\to M)\cdot\deg(g\colon B\to N).$$

Exercise 38.18.

(a) Let M be a smooth manifold and let X be a closed oriented smooth manifold. Furthermore let $f, g\colon X \to M$ be two smooth maps. Show that if there exists a smooth map $\pi\colon M \to X$ such that $\deg(\pi\circ f) \neq \deg(\pi\circ g)$, then f and g are not homotopic.

(b) Let M be the surface of genus 2. We consider the six maps $S^1 \to M$ shown in the figure below. Show that these six maps are pairwise not homotopic.

Exercise 38.19. In the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 we saw that every orientation-preserving diffeomorphism of $\mathbb{R}^n$ is diffeotopic to the identity. Give examples of orientation-preserving diffeomorphisms of suitable closed connected smooth manifolds that are not diffeotopic to the identity.
Hint. Consider products of spheres.

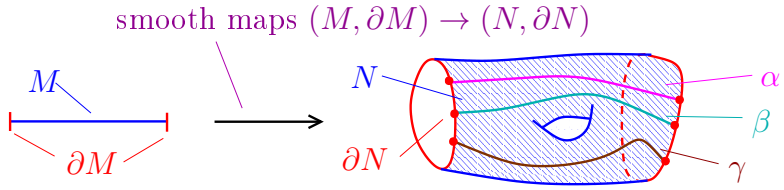
Exercise 38.20. Let $k \in \mathbb{N}_0$. Show that for every $g \geq k$ there exists a degree-one map from the surface Σ_g of genus g to the surface Σ_k of genus k.

Exercise 38.21. Let $n \in \mathbb{N}_{\geq 2}$. In the Matrix Group-Smooth Manifold Proposition 26.7 we showed that $\mathrm{SU}(n)$ is a closed orientable smooth manifold of dimension $\frac{1}{2}n \cdot (n-1)$. Show that for any $d \in \mathbb{Z}$ we have

$$\deg \begin{pmatrix} \mathrm{SU}(n) & \to & \mathrm{SU}(n) \\ A & \mapsto & A^d \end{pmatrix} = d^{n-1}.$$

Remark. This exercise is a special case of a much more general calculation of the degree of a power map on a Lie group in terms of the dimension of a maximal torus. We refer to [**HoM2020**, Lemma 6.92] for details.

Exercise 38.22. Let $f, g \colon S^n \to S^n$ be two maps. Show that if $\deg(f) \neq \deg(g)$, then there exists a point $x \in S^n$ with $\langle f(x), g(x) \rangle = 0$.
Hint. Consider $\|f(x) \cdot (1-t) + g(x) \cdot t\|$.



39. Degrees for smooth manifolds with boundary and the Borsuk-Ulam Theorem

In this chapter we will extend some of the definitions and the results from the previous chapter to maps between compact smooth manifolds, possibly with non-empty boundary. This extension is per se not particularly exciting. But we will use it to give our first of many proofs of the celebrated Borsuk-Ulam Theorem 39.8. In the next chapter we will then put the Borsuk-Ulam Theorem 39.8 to good use, namely we will use it to prove four theorems which at first and second glance are far removed from topology.

39.1. **Extension of degrees to smooth manifolds with boundary.** In the following we also intend to study suitable maps between compact oriented smooth manifolds with *non-empty* boundary. At this point it is convenient to introduce the following definitions.

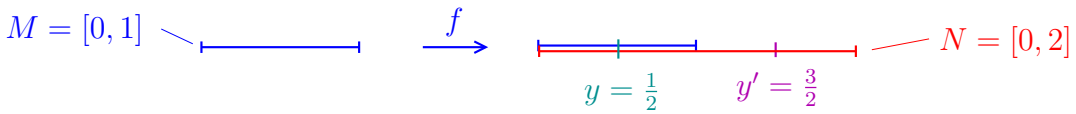
Definition.

(1) A pair of topological spaces is a pair (X, A) where X is a topological space and $A \subset X$.
(2) A map $f\colon (X, A) \to (Y, B)$ between pairs of topological spaces is a map[385] $f\colon X \to Y$ such that $f(A) \subset B$.
(3) We say two maps $f_0, f_1\colon (X, A) \to (Y, B)$ between pairs of topological spaces are homotopic if there exists a homotopy $F\colon X \times [0, 1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$ and such that for each $t \in [0, 1]$ we have $F_t(A) \subset B$.

$\alpha, \beta\colon (M, \partial M) \to (N, \partial N)$ are homotopic as maps between pairs of topological spaces,
$\alpha, \gamma\colon (M, \partial M) \to (N, \partial N)$ are *not* homotopic as maps of pairs of topological spaces

Now we can formulate the following extension of Theorem 38.1.

Theorem 39.1. Let M and N be two compact oriented connected non-empty smooth manifolds of the same dimension and let $f\colon (M, \partial M) \to (N, \partial N)$ be a smooth map. Let $y \in N \setminus \partial N$ be a regular value. The sum[386]



$$\sum_{x \in f^{-1}(y)} \deg(f, x) \ \in \ \mathbb{Z}$$

does not depend on the choice of y.

Proof. We postpone the proof of Theorem 39.1 to the end of the section. ∎

[385] As always, f is understood to be continuous.
[386] It follows from the Regular Value Theorem 26.4 that $f^{-1}(y)$ is a finite set. Furthermore it follows from the hypothesis that $f(\partial M) \subset \partial N$ and $y \in N \setminus \partial N$ that $f^{-1}(y) \subset M \setminus \partial M$. Thus it follows from the Inverse Mapping Theorem 24.1 that for any $x \in f^{-1}(y)$ the map f is a local diffeomorphism at x. Therefore the local degree $\deg(f, x)$ is defined as on page 898.

Non-Example. We consider the inclusion $f\colon [0,1] \to [0,2]$. Both $y = \frac{1}{2}$ and $y' = \frac{3}{2}$ are regular values, but $f^{-1}(y)$ consists of a single point whereas $f^{-1}(\frac{3}{2}) = \varnothing$. This shows that in Theorem 39.1 we cannot drop the hypothesis that $f(\partial M) \subset \partial N$.

Theorem 39.1 leads us to the following generalization of the definition on page 899.

Definition. Let M and N be two compact oriented connected non-empty smooth manifolds of the same dimension and let $f\colon (M, \partial M) \to (N, \partial N)$ be a smooth map. By Sard's Theorem 31.1 there exists a regular value $y \in N \setminus \partial N$. By Theorem 39.1 we can unambiguously define the degree of the smooth map f as

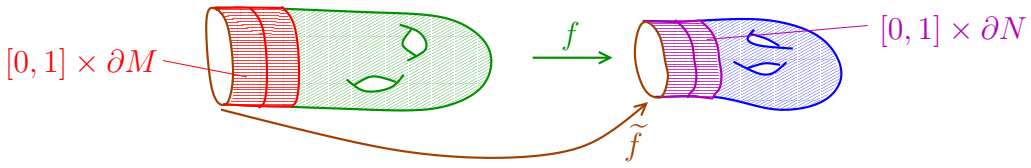
$$\deg(f) \;:=\; \sum_{x \in f^{-1}(y)} \deg(f, x) \;\in\; \mathbb{Z}.$$

Example. Let $n \in \mathbb{Z}$. We view $\overline{B}^2$ as a subspace of $\mathbb{C}$ and we consider the map

$$\begin{array}{rcl} f\colon \overline{B}^2 & \to & \overline{B}^2 \\ z & \mapsto & z^n. \end{array}$$

One can easily show that each $y \in B^2 \setminus \{0\}$ is a regular value. With $y = \frac{1}{2}$ we see that

$$\deg(f) \;=\; \sum_{k=1}^{|n|} \deg\Big(f, \underbrace{\exp\Big(\frac{-\ln(2)}{n} + 2\pi\,\mathrm{i}\cdot\frac{k}{|n|}\Big)}_{n\text{-th root of } \frac{1}{2}}\Big) \;=\; \sum_{k=1}^{|n|} \begin{cases} +1, & \text{if } n \geq 1, \\ -1, & \text{if } n < 1 \end{cases} \;=\; n.$$



↑ can be deduced using the Orientation Checking-via-Differentials Lemma 25.12

As before we would like to extend the definition of the degree to maps that are continuous but not necessarily smooth. To do so we need the following variation on the Whitney Approximation Theorem 29.1.

Theorem 39.2. (Relative Whitney Approximation Theorem) Let M and N be compact smooth manifolds. Every map $(M, \partial M) \to (N, \partial N)$ is homotopic, as a map of pairs of topological spaces, to a smooth map $(M, \partial M) \to (N, \partial N)$.

Proof. Let $f\colon (M, \partial M) \to (N, \partial N)$ be a map between compact smooth manifolds. By the Collar Neighborhood Theorem 28.3 there exist collars $[0,1] \times \partial M$ and $[0,1] \times \partial N$. We denote by $\widetilde{f}\colon \partial M \to \partial N$ the restriction of f. By the Whitney Approximation Theorem 29.1 we know that there exists a homotopy $\widetilde{F}\colon \partial M \times [0,1] \to \partial N$ with $\widetilde{F}_0 = \widetilde{f}$ and such that $\widetilde{F}_1$ is a smooth map. In fact, by the Trivial-Near-The-Ends-Lemma 33.4, we can assume that $\widetilde{F}_t = \widetilde{F}_1$ for all $t \in [\frac{1}{2}, 1]$. Now we consider the map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & N \\ (P,t) & \mapsto & \begin{cases} \widetilde{F}(Q, t - 2s), & \text{if } P = (s,Q) \in [0, \frac{1}{2}t] \times \partial M, \\ f((s - \frac{1}{2}t)\cdot\frac{1}{1-\frac{1}{2}t}, Q), & \text{if } P = (s,Q) \in [\frac{1}{2}t, 1] \times \partial M, \\ f(P), & \text{if} P \notin M \setminus ([0,1) \times M) \end{cases} \end{array}$$

It follows from the Pasting Proposition 2.6 together with the Basics-of-Collars Lemma 28.4 (1) that this map $F\colon M \times [0,1] \to N$ is continuous, thus it is indeed a homotopy. Note that for any $t \in [0,1]$ we have $F_t(\partial M) \subset \partial N$. Furthermore note that the restriction of $F_1\colon M \to N$ to $[0,\frac{1}{4}] \times \partial M$ is given by the composition of the projection $[0,\frac{1}{4}] \times \partial M$ to ∂M followed by the smooth map $\widetilde{F}_1$. Thus we see that the restriction of $F_1\colon M \to N$ to $[0,\frac{1}{4}] \times \partial M$ is smooth. In summary we have shown that the map $f\colon (M,\partial M) \to (N,\partial N)$ is homotopic to a map $F_1\colon (M,\partial M) \to (N,\partial N)$ that is smooth on $[0,\frac{1}{4}] \times \partial M$.

Now we can apply the Whitney Approximation Theorem 29.1 to the map $F_1\colon M \to N$ and the closed subset $A := [0,\frac{1}{4}] \times \partial M$. We see that there exists a homotopy rel A from F_1 to a smooth map $M \to N$. In summary we have now finally shown that the map $f\colon (M,\partial M) \to (N,\partial N)$ is indeed homotopic, as a map of pairs of topological spaces, to a smooth map $(M,\partial M) \to (N,\partial N)$. ■

To extend the definition of the degree to non-smooth maps we will also need the following analogue of Proposition 38.2.

Proposition 39.3. Let $g\colon M \to N$ be a map between two compact oriented connected non-empty smooth manifolds of the same dimension. If $f_0, f_1\colon (M,\partial M) \to (N,\partial N)$ are smooth maps that are both homotopic to g, then $\deg(f_0) = \deg(f_1)$.

Proof. We postpone the proof of Proposition 39.3 to the end of this section. ■

The Relative Whitney Approximation Theorem 39.2 and Proposition 38.2 allow us to make the following definition.

Definition. Let $f\colon (M,\partial M) \to (N,\partial N)$ be a map between two compact oriented connected non-empty smooth manifolds of the same dimension. By the Relative Whitney Approximation Theorem 39.2 we know that f is homotopic, as a map of pairs of topological spaces, to a smooth map $g\colon (M,\partial M) \to (N,\partial N)$. By Proposition 39.3 it makes sense to define

$$\deg(f) \;:=\; \deg(g).$$

Remark. On page 2222 we will give an alternative definition of the degree using the "fundamental class". Fortunately we will see in the Local-Global Degree Proposition 101.6 that the two definitions of the degree agree. Furthermore on page 2379 we will extend the notion of a degree to topological manifolds.

The following two theorems are the obvious extensions of the Degree Homotopy Invariance Theorem 38.3 and the Degree Multiplicativity Theorem 38.4.

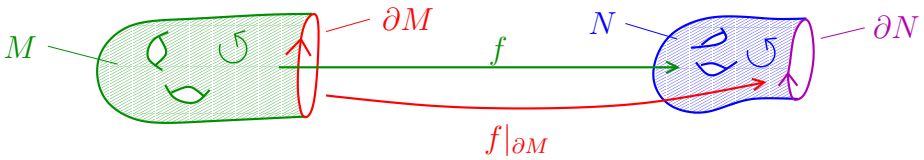
Theorem 39.4. (Degree Homotopy Invariance Theorem) Let M and N be two compact oriented connected non-empty smooth manifolds of the same dimension and let $f_0, f_1\colon (M,\partial M) \to (N,\partial N)$ be maps. If f_0 and f_1 are homotopic as maps of pairs of topological spaces, then

$$\deg(f_0) \;=\; \deg(f_1).$$

Theorem 39.5. (Degree Multiplicativity Theorem) Let L, M and N be three compact oriented connected non-empty smooth manifolds of the same dimension. Given any maps $f\colon (L, \partial L) \to (M, \partial M)$ and $g\colon (M, \partial M) \to (N, \partial N)$ we have the following equality:

$$\deg(g \circ f) \;=\; \deg(g) \cdot \deg(f).$$

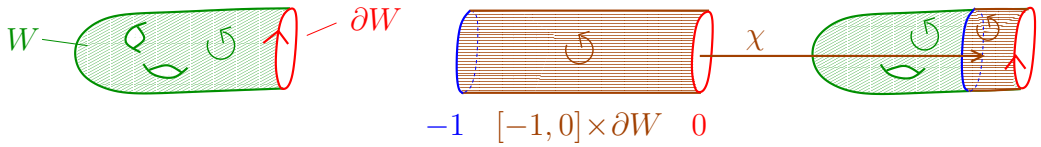
Proof of Theorems 39.1, 39.4 and 39.5 and the proof of Proposition 39.3. The proofs of Theorems 39.1, 39.4 and 39.5 and the proof of Proposition 39.3 for compact smooth manifolds with possibly non-empty boundary are, not surprisingly, very very similar to the proofs of Theorems 38.1, 38.3 and 38.4 and of Proposition 38.2 of the corresponding statements for closed smooth manifolds. To generalize the earlier proofs we need to make three observations. So suppose that M and N are compact connected smooth manifolds.



(1) If $y, z \in N \setminus \partial N$, then it follows from the Homogeneous-via-Diffeotopies Proposition 33.14 that there exists a diffeotopy $F\colon N \times [0,1] \to N$ with $F_0 = \mathrm{id}$ and $F_1(y) = z$.
(2) Let $f, g\colon (M, \partial M) \to (N, \partial N)$ be maps. If f and g are homotopic as maps of pairs of topological spaces, then they are also smoothly homotopic as maps of pairs of smooth manifolds. We will prove this slight generalization of the Replace-by-Smooth Homotopy Proposition 29.5 in Exercise 39.1.
(3) Let $f, g\colon (M, \partial M) \to (N, \partial N)$ be smooth maps and let $F\colon M \times [0,1] \to N$ be a smooth homotopy between the maps f and g of pairs of topological spaces. Furthermore let $z \notin \partial N$ be a regular value of $F\colon M \times [0,1] \to N$. Since $f(\partial M \times [0,1]) \subset \partial N$ we see that $F^{-1}(z) \subset (M \setminus \partial M) \times [0,1]$. In fact $Z := F^{-1}(z)$ is a submanifold of $(M \setminus \partial M) \times [0,1]$ such that $\partial Z \subset (M \setminus \partial M) \times \{0,1\}$. Since $M \times [0,1]$ is compact we see that Z is compact. In summary we see that $Z = F^{-1}(z)$ is a proper compact submanifold of $(M \setminus \partial M) \times [0,1]$.

With these three observations it is now straightforward to modify the earlier proofs. We leave it to the reader to fill in the details. ■

39.2. **The Boundary Degree Proposition.** Now we turn to the key result on our new more general notion of degree.



Proposition 39.6. (Boundary Degree Proposition) Let M and N be two compact oriented connected smooth manifolds of the same dimension, such that the boundary ∂M and ∂N are both connected and non-empty. We equip ∂M and ∂N with the boundary orientation that we had introduced on page 689. If $f\colon (M, \partial M) \to (N, \partial N)$ is a map, then

$$\deg(f\colon M \to N) \;=\; \deg(f|_{\partial M}\colon \partial M \to \partial N).$$

For the proof of the Boundary Degree Proposition 39.6 we will need the following slight variation on the Smooth Collar Neighborhood Theorem 28.3.

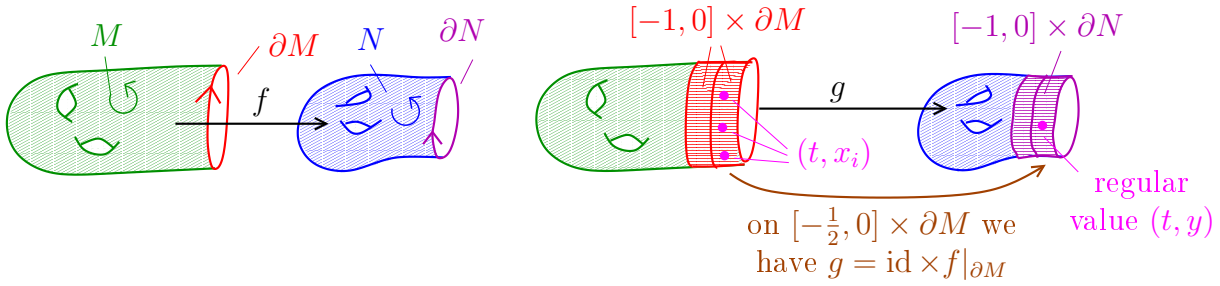
Lemma 39.7. Let W be a compact oriented smooth manifold. We equip ∂W with the boundary orientation, we equip $[-1,0] \subset \mathbb{R}$ with the standard orientation and we equip $[-1,0] \times \partial W$ with the product orientation. There exists an *orientation-preserving* smooth embedding $\chi\colon [-1,0] \times \partial W \to W$ such that the restriction of χ to $\{0\} \times \partial W$ is the obvious map $(0,P) \mapsto P$.

Proof of Lemma 39.7. It follows immediately from the Smooth Collar Neighborhood Theorem 28.3 that we can find a smooth embedding $\chi\colon [-1,0] \times \partial W \to W$ such that the restriction of χ to $\{0\} \times \partial W$ is the obvious map $(0,P) \mapsto P$. It follows from the Product Orientation Proposition 25.22 (4d) that, as an oriented smooth manifold, we have $\partial([-1,0] \times \partial W) = \partial([-1,0]) \times W = -(\{-1\} \times \partial W) \cup (\{0\} \times \partial W)$. It follows from the Boundary Orientation Lemma 25.17 (3) and (4) that χ is orientation-preserving. ■

Proof of the Boundary Degree Proposition 39.6. Let $f\colon (M,\partial M) \to (N,\partial N)$ be a map. It follows from the Relative Whitney Approximation Theorem 39.2 and the Degree Homotopy Invariance Theorem 39.4 that it suffices to consider the case that f is smooth.

It follows from Lemma 39.7 that we can find *orientation-preserving* smooth embeddings $\Phi\colon [-1,0] \times \partial M \to M$ and $\Psi\colon [-1,0] \times \partial N \to N$ such that for all $P \in \partial M$ we have $\Phi(0,P) = P$ and such that for all $Q \in \partial N$ we have $\Psi(0,Q) = Q$. To simplify the notation we identify $[-1,0] \times \partial M$ with its image under Φ and the same way we proceed with $[-1,0] \times \partial N$ and Ψ. Note that it follows from the Codimension-Zero Smooth Embedding Proposition 24.16 that $(-1,0] \times \partial M \subset M$ and $(-1,0] \times \partial N \subset N$ are open subsets.

By the Homotopic-to-Product-Near-Boundary Lemma 28.6 we know that the map $f\colon (M,\partial M) \to (N,\partial N)$ is homotopic to a map $g\colon (M,\partial M) \to (N,\partial N)$ with the following two properties:



(1) For every $(t,P) \in [-\frac{1}{2},0] \times \partial M$ we have $g(t,P) = (t,f(P)) \in [-\frac{1}{2},0] \times \partial N$.
(2) We have $g^{-1}([-\frac{1}{2},0] \times \partial N) = [-\frac{1}{2},0] \times \partial M$.

Note that a priori we do not know whether $g\colon M \to N$ is smooth. But note that the map $g\colon [-\frac{1}{2},0] \times \partial M \to [-\frac{1}{2},0] \times \partial N$ is smooth. By Sard's Theorem 31.1, together with Proposition 30.3, we know that there exists a regular value $(t,y) \in (-\frac{1}{2},0) \times \partial N$ of $g\colon [-\frac{1}{2},0] \times \partial M \to [-\frac{1}{2},0] \times \partial N$. It follows from (1) and (2) that the preimages of (t,y)

are of the form $(t, x_1), \dots, (t, x_k)$ with $x_1, \dots, x_k \in \partial M$. We see that

$$\begin{array}{rcl} \deg(f\colon M \to N) & \overset{\text{by Theorem 38.3, since } f \text{ and } g \text{ are homotopic}}{=} & \deg(g\colon M \to N) \\ & = & \sum_{i=1}^{k} \deg(\mathrm{id} \times f|_{\partial M}\colon [-\tfrac{1}{2}, 0] \times \partial M \to [-\tfrac{1}{2}, 0] \times \partial N, (t, x_i)) \\ & \overset{\text{by (1) the map } g\colon [-\frac{1}{2},0]\times\partial M \to [-\frac{1}{2},0]\times\partial N \text{ is given by } \mathrm{id}\times f|_{\partial M}, \text{ here we implicitly use that } [-1,0]\times\partial M \to M \text{ and } [-1,0]\times\partial N \to N \text{ are orientation-preserving}}{=} & \sum_{i=1}^{k} \deg(f|_{\partial M}\colon \partial M \to \partial N, x_i) \\ & \overset{\text{it follows from the Product Orientation Preserving Lemma 25.23 that the corresponding local degrees are the same}}{=} & \overset{\text{follows from (1) and (2) and the Degree of Partially Smooth Map Lemma 38.14}}{\sum_{i=1}^{k} \deg(g, (t, x_i))} \\ & \overset{\text{by definition of the degree}}{=} & \deg(f|_{\partial M}\colon \partial M \to \partial N). \end{array}$$

■

39.3. **The Borsuk-Ulam Theorem.** We start out with the following simple definition.

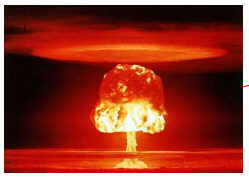
Definition. Let $A \subset S^n$ be a subset. We say two points $x, y \in A$ are antipodal if $y = -x$.

The following theorem is arguably the most interesting result one can prove with the methods and tools of this chapter.

Theorem 39.8. (Borsuk-Ulam Theorem) Let $n \in \mathbb{N}_0$. For every map $f\colon S^n \to \mathbb{R}^n$ there exists a pair of antipodal points x and $-x$ on S^n with $f(x) = f(-x)$.

Example. If we think of the surface of earth as S^2, then it follows from the Borsuk-Ulam 39.8 that there exists a pair of antipodal points where the temperature and air pressure agree.

Remark.



(1) The statement of the Borsuk-Ulam Theorem was conjectured by Stanislaw Ulam, see [**Bor1933**, p. 178]. The theorem was first proved by Karol Borsuk [**Bor1933**] in 1933.
   (a) Karol Borsuk (1905-1982) was a Polish mathematician. He lost his job at the University of Warsaw after the German invasion in 1939. To survive financially he developed a board game and produced and sold it during the war. Almost all copies of the game were lost during the Warsaw uprising in 1944, but in the

1990s one surviving copy was found and the game was republished. We refer to

`https://en.wikipedia.org/wiki/Animal_Husbandry_(game)`

for more details.

(b) Stanislaw Ulam (1909-1984) was a Polish mathematician and nuclear scientist. He was one of the fathers of the hydrogen bomb.

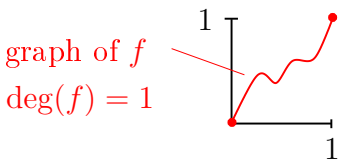
Ulam's other contribution to mankind

(2) In Sections 91.3, 97.6 and 121.3 we will provide three other proofs of the Borsuk-Ulam Theorem 39.8. Furthermore in Theorem 48.21 we will provide a different proof for the special case $n = 2$.

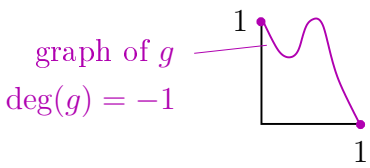
(3) The Borsuk-Ulam Theorem 39.8 has many beautiful applications, in particular the Lusternik-Schnirelmann Theorem 40.1, the Ham-Sandwich Theorem 40.2, Pfister's Level Theorem 40.9 and, my favorite, the Necklace Theorem 40.11. Beyond these theorems the Borsuk-Ulam Theorem has an almost endless string of consequences, many of which lie in combinatorics and graph theory, we refer to [**Mato2008, Steinl1985, Steinl1993**] for an extensive discussion of the Borsuk-Ulam theorem and its corollaries.

The key ingredient in our proof of the Borsuk-Ulam Theorem 39.8 is the Smooth Odd Degree Proposition 39.9. To formulate this proposition we need the following straightforward definition.

Definition. A map $f\colon S^n \to S^n$ is called odd, if $f(-x) = -f(x)$ for all $x \in S^n$.



Proposition 39.9. (Smooth Odd Degree Proposition) Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a smooth map. If f is odd, then $\deg(f)$ is odd.



Remark. In the Odd Degree Proposition 91.3 we will use homology theory to provide an alternative proof of the Smooth Odd Degree Proposition 39.9. In fact at that point we will only need that f is continuous.

Eventually we will prove the Smooth Odd Degree Proposition 39.9 by induction on n. For the starting point we will need the following elementary lemma.

Auxiliary Lemma 39.10. Let M and N be two compact oriented connected 1-dimensional smooth manifolds of the same dimension with non-empty boundary. Furthermore let $f\colon (M, \partial M) \to (N, \partial N)$ be a smooth map. If $f\colon \partial M \to \partial N$ is a diffeomorphism, then

$$\deg(f\colon M \to N) \;=\; \begin{cases} +1, & \text{if } f\colon \partial M \to \partial N \text{ is orientation-preserving,} \\ -1, & \text{if } f\colon \partial M \to \partial N \text{ is orientation-reversing.} \end{cases}$$

Proof of Lemma 39.10. By the Smooth 1-Dimensional Manifold Classification Theorem 22.7 we can assume that $M = N = [0,1]$. Note that

$$\begin{array}{rcl} F\colon [0,1]\times[0,1] & \to & [0,1] \\ (x,t) & \mapsto & f(x)\cdot(1-t) + ((1-x)\cdot f(0) + x\cdot f(1))\cdot t \end{array}$$

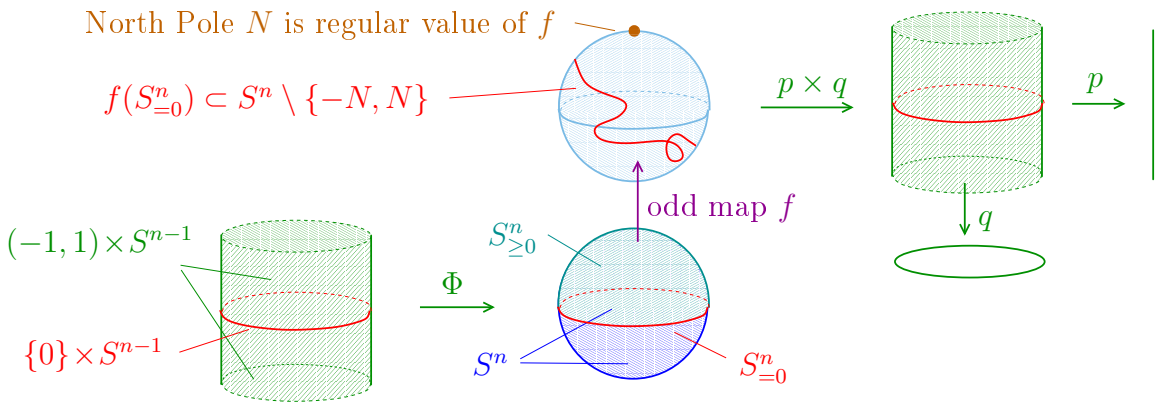
is a homotopy of maps $([0,1],\{0,1\}) \to ([0,1],\{0,1\})$. If $f(0) = 0$ and $f(1) = 1$, then F is a homotopy from f to the map $t \mapsto t$ and $f(0) = 0$ and $f(1) = 1$, then F is a homotopy from f to the map $t \mapsto 1-t$. Either way it follows from the Degree Homotopy Invariance Theorem 38.3 that $\deg(f) \pm 1$. ∎

Proof of the Smooth Odd Degree Proposition 39.9. We want to prove the proposition by induction on n. In the following we will prove the case $n = 1$ and the induction step $n-1 \rightsquigarrow n$ by almost the same argument. Only at the very end will the two arguments diverge slightly.

In the following let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a smooth map that is odd. We introduce the following notation which we will use throughout this proof:

- We denote by $N := (0,\dots,0,1)$ the North Pole of S^n.
- As on page 152 we denote by $S^n_{\geq 0}$ the upper hemisphere and we denote by $S^n_{=0}$ the equator of S^n. Given a map $g\colon S^n \to M$ we denote by $g_{\geq 0}$ and $g_{=0}$ the obvious restrictions.
- We consider the smooth embedding

$$\begin{array}{rcl} \Phi\colon (-1,1)\times S^{n-1} & \to & S^n \\ (t,x) & \mapsto & \dfrac{(0,x)+t\cdot N}{\|(0,x)+t\cdot N\|}. \end{array}$$



- We consider the maps

$$\begin{array}{rcl} p\colon S^n & \to & [-1,1] \\ (x_1,\dots,x_n,x_{n+1}) & \mapsto & x_{n+1} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} q\colon S^n\setminus\{\pm N\} & \to & S^{n-1} \\ (x_1,\dots,x_n,x_{n+1}) & \mapsto & \dfrac{(x_1,\dots,x_n)}{\|(x_1,\dots,x_n)\|}. \end{array}$$

  Evidently $(p\circ q)\circ\Phi = \mathrm{id}_{(-1,1)\times S^{n-1}}$.

It follows from Sard's Theorem 31.1, together with the Measure-Zero Properties Proposition 30.2, that there exists a $v \in S^n$ which is a regular value of the smooth map $f\colon S^n \to S^n$ and also of the smooth map $f_{=0}\colon S^n_{=0} \to S^n$.

Note that by the Orthogonal Action Lemma 5.26 there exists an orthogonal matrix $A \in \mathrm{O}(n+1)$ with $A\cdot v = N$. Next note that $x \mapsto A\cdot f(x)$ is still odd and note that by the Degree Multiplicativity Theorem 38.4 and the discussion on page 905 we know that $\deg(x \mapsto A\cdot f(x)) = \deg(f)$. This shows that, after composing f with the map that is given by multiplication by A, we might as well assume that $v = N$. Note that since f is odd we see that in fact both N and $-N$ are regular values of $f\colon S^n \to S^n$ and of $f_{=0}\colon S^n_{=0} \to S^n$.

Claim 1. The map f is homotopic to an odd smooth map $g\colon S^n \to S^n$ such that $\pm N$ are again regular values of g and such that g satisfies $g(S^n_{=0}) \subset S^n_{=0}$.[387]

Proof. Since $S^n_{n=0} = \Phi(\{0\} \times S^{n-1})$ is an $(n-1)$-dimensional smooth manifold we see that the fact that $\pm N$ is a regular value of $f\colon S^n_{n=0} \to S^n$ implies that $\pm N \notin (f \circ \Phi)(\{0\} \times S^{n-1})$. An elementary compactness argument, see Exercise 5.9, shows that there exists an $\epsilon \in (0,1)$ such that

$$(f \circ \Phi)([-\epsilon, \epsilon] \times S^{n-1}) \ \subset \ S^n \setminus \{\pm N\}.$$

It follows easily from the Smooth Transition Function Lemma 19.4 that can pick a smooth map $\eta\colon [-\epsilon, \epsilon] \to [0,1]$ such that $\eta(x) = 1$ for $|x| \geq \frac{\epsilon}{2}$, $\eta(0) = 0$ and which is even in the sense that $\eta(-x) = \eta(x)$. Next we consider the map

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \to & S^n \\ (z,s) & \mapsto & \begin{cases} f(z), & \text{if } |p(z)| \geq \epsilon, \\ \Phi(\underbrace{p(f(z)) \cdot (1 - s + s \cdot \eta(p(z)))}_{\in [-\epsilon, \epsilon]}, q(f(z))), & \text{if } |p(z)| \leq \epsilon. \end{cases} \end{array}$$

Note that $F_0 = f$. Since η is smooth we see that each F_s is smooth. Furthermore, since η is symmetric one can easily verify that each F_s is odd. Furthermore note that it follows from $\eta(0) = 0$ that $F_1(S^n_{=0}) \subset S^n_{=0}$. We set $g := F_1$. It remains to show that $\pm N$ are also regular values for g. This can be seen as follows. First recall that $\pm N$ are regular values of f. Next note that by construction of g there exists an open neighborhood U of $\{-N, N\} \subset S^n$, namely $U := S^n \setminus F([-\epsilon, \epsilon] \times S^{n-1} \times [0,1])$, such that $f^{-1}(U) = g^{-1}(U)$ and such that f and g agree on this subset. But this implies that $\pm N$ are also regular values for g. ⊞

Before we can state the next claim we need to add one more piece of notation to the above list.

- We denote by $\pi\colon S^n \to \overline{B}^n$ the projection onto the first n coordinates.

Claim 2. We equip $S^n_{\geq 0}$ with the submanifold orientation coming from S^n and we equip $\overline{B}^n$ with the standard orientation. With these orientations we have the following equality:

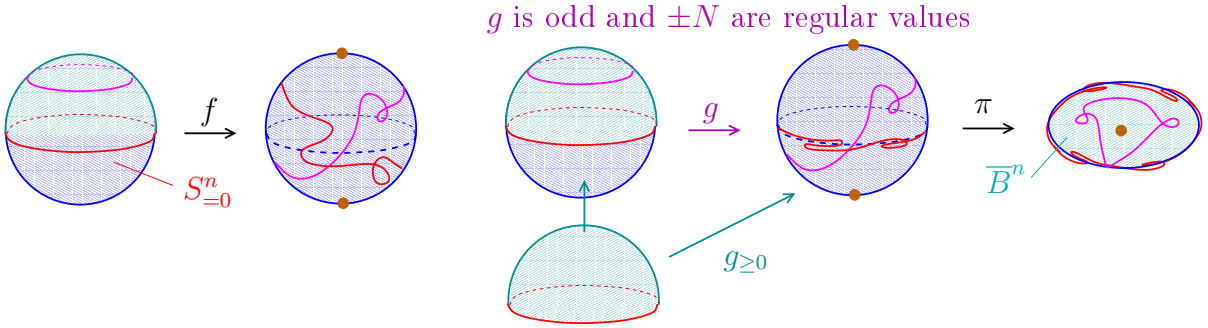
$$\deg(g\colon S^n \to S^n) \ \equiv \ \deg(\ \underbrace{\pi \circ g_{\geq 0}\colon S^n_{\geq 0} \to \overline{B}^n}_{\text{defined since } g_{=0}(S^n_{=0}) \subset S^n_{=0}}\ ) \mod 2.$$

[387] Note that we do not claim that one can arrange that $g(S^n_{\geq 0}) \subset S^n_{\geq 0}$.

Proof. We calculate that in $\mathbb{Z}_2 = \mathbb{Z}/2\mathbb{Z}$, or $\mathbb{R}/2\mathbb{Z}$, we have following equalities:

$$\begin{array}{rcl} \deg(g\colon S^n \to S^n) & \overset{\text{since } \pm N \text{ are both regular values of } g \text{ and since mod } \mathbb{Z} \text{ we ignore signs}}{\downarrow\equiv} & \tfrac{1}{2}\cdot\#g^{-1}(N) + \tfrac{1}{2}\cdot\#g^{-1}(-N) \\ & = & \#(\pi\circ g_{\geq 0})^{-1}(0) \\ & \underset{\text{since } \pi^{-1}(0)=\{\pm N\}}{\uparrow=} & \end{array} \qquad \begin{array}{rcl} & \overset{\text{since } g \text{ is odd and since } g(S^n_{=0}) \subset S^n \setminus \{\pm N\}}{\downarrow=} & \#g_{\geq 0}^{-1}(N) + \#g_{\geq 0}^{-1}(-N) \\ & \equiv & \deg(\pi\circ g\colon S^n_{\geq 0} \to \overline{B}^n). \\ & \underset{\text{since } \mathrm{D}\pi_N \text{ is an isomorphism we see that } 0 \text{ is a regular value of } \pi\circ g_{\geq 0}}{\uparrow} & \end{array}$$

⊞



At this point we have to distinguish the cases $n = 1$ and $n \geq 2$. First we deal with the case $n = 1$. We perform the following calculation in $\mathbb{Z}_2$:

$$\deg(f\colon S^1 \to S^1) \overset{\text{by the Degree Homotopy Invariance Theorem 38.3 since } f \text{ and } g \text{ are homotopic}}{\downarrow=} \deg(g\colon S^1 \to S^1) \overset{\text{by Claim 2}}{\downarrow=} \deg(\pi\circ g_{\geq 0}\colon S^1_{\geq 0} \to \overline{B}^1) \underset{\text{follows from Lemma 39.10, since the fact that } g_{=0} \text{ is odd implies that } \pi\circ g_{\geq 0}\colon S^1_{=0} \to S^0 \text{ is a diffeomorphism}}{\uparrow=} \pm 1.$$

Finally let us do the induction step. So now we assume that the conclusion holds for some $n - 1 \in \mathbb{N}$ and we want to show that it holds for n. We perform a very similar calculation in $\mathbb{Z}_2$ as above:

$$\begin{array}{rcl} \deg(f\colon S^n \to S^n) & \overset{\text{by the Degree Homotopy Invariance Theorem 38.3 since } f \text{ and } g \text{ are homotopic}}{\downarrow=} & \deg(g\colon S^n \to S^n) \\ & \underset{\text{by the Boundary Degree Proposition 39.6}}{\uparrow=} & \deg(\pi\circ g_{=0}\colon S^n_{=0} \to S^{n-1}) \end{array} \qquad \begin{array}{rcl} & \overset{\text{by Claim 2}}{\downarrow=} & \deg(\pi\circ g_{\geq 0}\colon S^n_{\geq 0} \to \overline{B}^n) \\ & \underset{\text{since } x \mapsto (x,0) \text{ is a diffeomorphism } S^n_{=0} \to S^{n-1}}{\uparrow=} & \deg\left(S^{n-1} \xrightarrow{x \mapsto (\pi\circ g)(x,0)} S^{n-1}\right) \underset{\text{by our hypothesis on } n-1}{\uparrow=} \text{odd}. \end{array}$$

■

Now we can finally provide the proof of the Borsuk-Ulam Theorem 39.8. We split the proof into two parts. First we consider the case that f is smooth, afterwards we consider the general case.

Proof of the Borsuk-Ulam Theorem 39.8 for smooth maps. Let $n \in \mathbb{N}_0$ and let $f\colon S^n \to \mathbb{R}^n$ be a smooth map. We need to show that there exists an $x \in S^n$ with $f(-x) = f(x)$. The case $n = 0$ is trivial so we only need to deal with the case $n \in \mathbb{N}$.

Suppose there exists no pair of antipodal points x and $-x$ in S^n with $f(x) = f(-x)$. Put differently, suppose that for every $x \in S^n$ we have $f(x) \neq f(-x)$. We consider the

composition of the following two maps

$$\begin{array}{rcccl} \Phi\colon S^{n-1}\times[0,1] & \to & S^n_{\geq 0} & \to & S^{n-1}. \\ (y,t) & \mapsto & (y\cdot\sqrt{1-t^2},t) & & \\ & & x & \mapsto & \underbrace{\frac{f(x)-f(-x)}{\|f(x)-f(-x)\|}}_{\text{defined since } f(x)\neq f(-x)} \end{array}$$

A quick look at the definitions shows that Φ_0 is odd and it shows that Φ_1 is a constant map. Thus we see that

$$\begin{array}{ccccccc} & & & & \overset{\text{by the Degree Homotopy Invariance Theorem 38.3, since } \Phi_0 \text{ and } \Phi_1 \text{ are homotopic}}{\downarrow} & & \\ \text{odd number} & = & \deg(\Phi_0) & = & \deg(\Phi_1) & = & \deg(\text{constant map}) & = & 0. \\ & & \uparrow & & \uparrow & & \uparrow & & \\ & & \text{since } \Phi_0 \text{ is odd we obtain from the Smooth Odd Degree Proposition 39.9 that } \deg(\Phi_0) \text{ is odd} & & \text{by definition of } \Phi_1 & & \text{by the Basics of Degree Lemma 38.8 (1) since constant maps are not surjective} & & \end{array}$$

We have thus obtained a contradiction. ■

Proof of the Borsuk-Ulam Theorem 39.8 for continuous maps. Let $f\colon S^n \to \mathbb{R}^n$ be a continuous map. Suppose there exists no pair of antipodal points x and $-x$ in S^n with $f(x) = f(-x)$. It follows that the map

$$\begin{array}{rcl} \varphi\colon S^n & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & \|f(x)-f(-x)\| \end{array}$$

is never zero. Since S^n is compact we see that there exists an $\epsilon > 0$ such for all $x \in S^n$ we have $\|f(x)-f(-x)\| \geq \epsilon$.

By the Smooth Approximation Proposition 21.10 there exists a *smooth* map $\widetilde{f}\colon S^n \to \mathbb{R}^n$ such that for every $x \in S^n$ we have $\|f(x)-\widetilde{f}(x)\| < \frac{\epsilon}{2}$. It follows from the triangle inequality that for every $x \in S^n$ we have $\|\widetilde{f}(x)-\widetilde{f}(-x)\| > 0$. But this contradicts the Smooth Borsuk Ulam Theorem that we had just proved above. ■

Exercises for Chapter 39.

Exercise 39.1. Let M and N be compact smooth manifolds. Let $f, g\colon (M,\partial M) \to (N,\partial N)$ be two smooth maps. We suppose that there exists a homotopy $F\colon M\times[0,1] \to N$ of maps of pairs of topological spaces from f to g.

(a) Show that there exists a homotopy $G\colon M\times[0,1] \to N$ of maps of pairs of topological spaces from f to g such that G is smooth on a neighborhood of $\partial M \times [0,1]$.

(b) Show that there exists a smooth homotopy $G\colon M\times[0,1] \to N$ of maps of pairs of topological spaces from f to g.

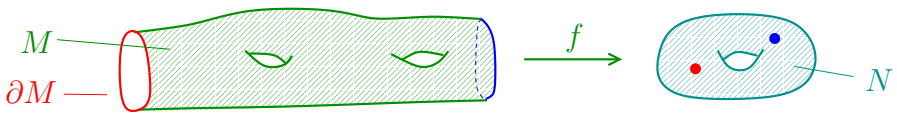
Hint. For (a) use the Smooth Collar Neighborhood Theorem 28.3 and the Replace-by-Smooth Homotopy Proposition 29.5. For (b) modify the proof of the Replace-by-Smooth Homotopy Proposition 29.5.

Exercise 39.2. Let M and N be compact smooth manifolds. Let $f, g\colon M \to N$ be two smooth maps with $f|_M = g|_M$. We suppose that there exists a homotopy $F\colon M\times[0,1] \to N$ rel ∂M from f to g.

(a) Show that there exists a homotopy $G\colon M \times [0,1] \to N$ rel ∂M from f to g such that G is smooth on a neighborhood of $\partial M \times [0,1]$.
(b) Show that there exists a smooth homotopy $G\colon M \times [0,1] \to N$ rel ∂M from f to g.

Hint. For (a) use the Smooth Collar Neighborhood Theorem 28.3 and the Replace-by-Smooth Homotopy Proposition 29.5. For (b) modify the proof of the Replace-by-Smooth Homotopy Proposition 29.5.

Exercise 39.3. Let $n \in \mathbb{N}$ and let $f\colon \overline{B}^n \to \overline{B}^n$ be a smooth map such that the restriction $f\colon S^{n-1} \to S^{n-1}$ is a diffeomorphism. Show that $f\colon \overline{B}^n \to \overline{B}^n$ is surjective.
Remark. The case $n = 1$ is equivalent to the Intermediate Value Theorem from real analysis.



Exercise 39.4.

(a) Generalize the $\mathbb{Z}_2$-degree from page 913 to the setting of maps $(M, \partial M) \to (N, \partial N)$ between compact connected smooth manifolds.
(b) Show that the analogue of Boundary Degree Proposition 39.6 also holds for $\mathbb{Z}_2$-degrees.
(c) Use (b) to give a new proof of the Boundary Non-Retraction Proposition 31.3.

Exercise 39.5. Let M be a compact smooth manifold with non-empty boundary and let N be a closed smooth manifold. Let $f\colon M \to N$ be a smooth map. Given a regular value $y \in N$ we set

$$\deg_y(f) \;:=\; \sum_{x \in f^{-1}(y)} \deg(f,x) \;\in\; \mathbb{Z}.$$

(a) Show that in general the definition of $\deg_y(f)$ depends on the choice of the regular value y.
(b) We suppose that $f\colon M \to N$ is a smooth map which is locally constant on ∂M. Show that in this setting the definition of $\deg_y(f)$ does not depend on the choice of the regular value y.

Exercise 39.6. Let M be a compact connected oriented n-dimensional smooth manifold such that ∂M is connected and non-empty. Show that there exists a map $f\colon M \to \overline{B}^n$ of degree $+1$.

Exercise 39.7. Prove the Borsuk-Ulam Theorem 39.8 for 1-dimensional spheres using methods from real analysis. In other words, show, just using methods from real analysis, that given any map $f\colon S^1 \to \mathbb{R}$ there exists an $x \in S^1$ with $f(-x) = f(x)$.

Exercise 39.8. Let $n \in \mathbb{N}$. Show that the following are equivalent statements:

(a) For every map $f\colon S^n \to \mathbb{R}^n$ there exists an $x \in S^n$ with $f(x) = f(-x)$.
(b) For every odd map $f\colon S^n \to \mathbb{R}^n$ there exists an $x \in S^n$ with $f(x) = 0$.
(c) There is no odd map $f\colon S^n \to S^{n-1}$.
(d) There is no map $f\colon \overline{B}^n \to S^{n-1}$ such that the restriction of f to $S^{n-1} \to S^{n-1}$ is odd.

Exercise 39.9. Let $n \in \mathbb{N}$. Show that the Borsuk-Ulam Theorem 39.8 implies the Brouwer Fixed Point Theorem 31.4.
Remark. From Exercise 39.8 you can pick your favorite formulation of the Borsuk-Ulam Theorem 39.8.

Exercise 39.10. Let $n \in \mathbb{N}$.

(a) Let $f\colon S^n \to S^n$ be a map. Show that if the map f factors through the projection $p\colon S^n \to \mathbb{R}\mathrm{P}^n$, then $\deg(f)$ is even.

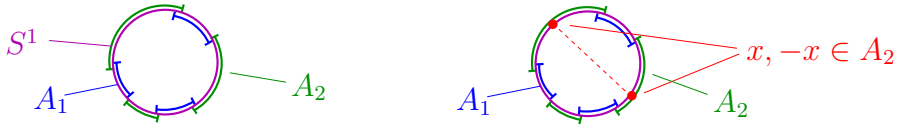
(b) Let $f\colon S^n \to S^n$ be a map of odd degree. Show that there exists an $x \in S^n$ with $f(-x) = -f(x)$.
Hint. Prove the statement by contradiction and make use of (a).
Remark. This statement can be viewed as a partial converse to the Smooth Odd Degree Proposition 39.9.

40. Applications of the Borsuk-Ulam Theorem

In this chapter we will state and prove several particularly interesting consequences of the Borsuk-Ulam Theorem 39.8.

40.1. **The Ham-Sandwich Theorem.** Before we can state our first application of the Borsuk-Ulam Theorem 39.8 we need to recall the following harmless definition from page 929.

Definition. Let $A \subset S^n$ be a subset. We say two points $x, y \in A$ are antipodal if $y = -x$.



The following application of the Borsuk-Ulam Theorem 39.8 was first proved by the Soviet mathematicians Lazar Lusternik and Lev Schnirelmann [**LuS1930**, p. 26-31] in 1930 using different methods.

Theorem 40.1. (Lusternik-Schnirelmann Theorem) Let $A_1, \dots, A_{n+1}$ be closed subsets of S^n with $A_1 \cup \dots \cup A_{n+1} = S^n$. Then there exists an $i \in \{1, \dots, n+1\}$ such that A_i contains a pair of antipodal points.

Remark. In the Generalized Lusternik-Schnirelmann Theorem 40.7 we will prove a slight generalization of the Lusternik-Schnirelmann Theorem 40.1.

Examples.

(1) For $n = 1$ we obtain from the Lusternik-Schnirelmann Theorem 40.1 that if we have a decomposition $S^1 = A_1 \cup A_2$ where A_1 and A_2 are two closed subsets (which do not need to be connected), then the subset A_1 or the subset A_2 contains a pair of antipodal points x and $-x$. In Exercise 40.1 we will give a naive proof for the special case $n = 1$.

(2) We consider the surface of our earth, we take A_1 to be the closure of the land mass, we take A_2 to be the closure of the Pacific ocean and we take A_3 to be the closure of all seas except for the Pacific. Then the Lusternik-Schnirelmann Theorem 40.1 says that at least one of A_1, A_2 or A_3 contains a pair of antipodal points. Which of A_1, A_2 and A_3 contains a pair of antipodal points?

(3) The Lusternik-Schnirelmann Theorem 40.1 is optimal in the following sense: in Exercise 40.2 we will see that given any $n \in \mathbb{N}_0$ we can find closed subsets $A_1, \dots, A_{n+2}$ that cover all of S^n, but such that none of the A_i contains a pair of antipodal points.

Proof. Let $A_1, \dots, A_{n+1}$ be closed subsets of S^n with $A_1 \cup \dots \cup A_{n+1} = S^n$. Without loss of generality we can assume that all $A_1, \dots, A_{n+1}$ are non-empty.[388] Given a non-empty subset A of S^n and $x \in S^n$ we consider, as on page 283, the distance from x to A:

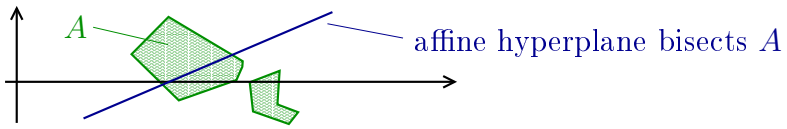
$$d(x, A) := \inf\{\|x - a\| \mid a \in A\},$$

where $\|x - a\|$ denotes the usual Euclidean distance on $S^n \subset \mathbb{R}^{n+1}$. By the Distance-to-Subspace the Distance-to-Subspace Lemma 6.2 together with Exercise 1.3 we know that the following two statements hold:

[388] Evidently at least one A_i is non-empty. So if one of the A_i is empty we just replace it with one of the non-empty ones.

(a) If A is closed, then $d(x, A) = 0$ if and only if $x \in A$.
(b) The map $x \mapsto d(x, A)$ is continuous.

We consider the map



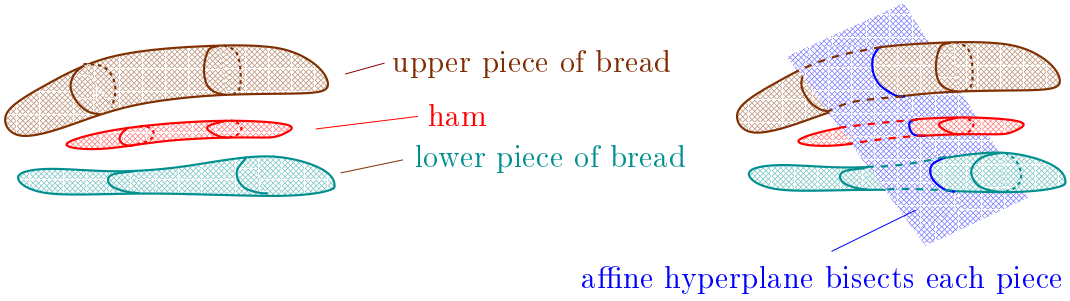
$$\begin{array}{rccc} f\colon & S^n & \to & \mathbb{R}^n \\ & x & \mapsto & (d(x, A_1), \ldots, d(x, A_n)). \end{array}$$

It follows from (b) that this map is indeed continuous. By the Borsuk-Ulam Theorem 39.8 there exists an $x \in S^n$ with $f(x) = f(-x)$. We distinguish three cases:

(1) If there exists an $i \in \{1, \ldots, n\}$ such that $x \in A_i$, then it follows from $f(x) = f(-x)$ that $d(-x, A_i) = d(x, A_i) = 0$. Since A_i is closed it follows from (a) that $-x \in A_i$.
(2) If there exists an $i \in \{1, \ldots, n\}$ such that $-x \in A_i$, then the argument of (1) shows that we also have $x \in A_i$.
(3) If neither x nor $-x$ lies in one of the A_i, then $x, -x$ both lie in A_{n+1}. ■

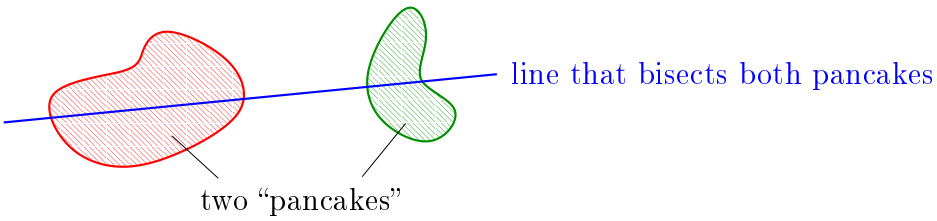
Before we can state the next consequence of the Borsuk-Ulam Theorem 39.8 we need to introduce one more definition.

Definition. Let $A \subset \mathbb{R}^n$ be a measurable subset[389] of finite volume. We say an affine hyperplane $H \subset \mathbb{R}^n$ bisects A if for the two half-spaces V, V' determined by H we have the equality $\mathrm{vol}(A \cap V) = \mathrm{vol}(A \cap V')$.



We continue with the following pretty theorem.

Theorem 40.2. (Ham-Sandwich Theorem) Let $A_1, \ldots, A_n$ be measurable finite-volume subsets of $\mathbb{R}^n$. Then there exists an $(n-1)$-dimensional affine hyperplane in $\mathbb{R}^n$ that bisects $A_1, \ldots, A_n$.



Remark.

(1) The Ham-Sandwich Theorem gets its name from the following "application". Suppose we are given a sandwich with an upper piece of bread A_1, some ham A_2 and a lower piece of bread A_3. Then using a knife one can cut the sandwich, along an affine hyperplane, into two pieces such that each piece of bread and the ham are bisected. This situation is, more or less convincingly, illustrated in the figure below.

[389] Here "measurable" means Lebesgue-measurable in the sense of say [**Caro2000**] or [**RudiW1987**, Chapter 2].

(2) The 2-dimensional version of the Ham-Sandwich Theorem is sometimes referred to as the "Pancake Theorem", since one can bisect the two pancakes along a line into two equal sized halves.

(3) The Ham-Sandwich Theorem is sometimes also called, more prosaically, the Stone-Tukey theorem after the mathematicians Arthur Stone and John Tukey [**StT1942**].

In the proof of the Ham-Sandwich Theorem we will need the following result from measure theory.

Proposition 40.3. Suppose that for each $t \in \mathbb{R}$ we have a measurable subset X_t of $\mathbb{R}^n$ such that for each $s \leq t \in \mathbb{R}$ we have $X_s \subset X_t$. Then $\bigcup_{t\in\mathbb{R}} X_t$ is also measurable and

$$\lim_{t\to\infty} \operatorname{vol}(X_t) \;=\; \operatorname{vol}\Big(\bigcup_{t\in\mathbb{R}} X_t\Big).$$

Proof of Proposition 40.3. The proposition can be deduced easily from basic facts of the Lebesgue measure, see [**Caro2000**, Chapter 16]. ■

Proof of the Ham-Sandwich Theorem 40.2. Let $A_1, \ldots, A_n$ be measurable finite-volume subsets of $\mathbb{R}^n$. If all A_i have volume zero, then there is nothing to prove. Thus, without loss of generality we can assume that the volume of A_n is positive. Given a point $P \in S^{n-1}$ and $t \in \mathbb{R}$ we write

$$\begin{aligned} H_{P,t} &:= \{t \cdot P + w \mid \langle P, w\rangle = 0\} \\ V^+_{P,t} &:= \{t \cdot P + w \mid \langle P, w\rangle \geq 0\} \\ V^-_{P,t} &:= \{t \cdot P + w \mid \langle P, w\rangle \leq 0\}. \end{aligned}$$

(We refer to the figure below on the left for an illustration.) Put differently, $H_{P,t}$ is the affine hyperplane through $t \cdot P$ orthogonal to P, and $V^{\pm}_{P,t}$ are the two half-spaces determined by $H_{P,t}$. We make the following two observations:

(i) by definition we have $V^{\pm}_{-P,-t} = V^{\mp}_{P,t}$,

(ii) for a subset $A \subset \mathbb{R}^n$ of finite volume we have the equality

$$\operatorname{vol}(A \cap V^{\pm}_{P,t}) \underset{\uparrow}{=} \operatorname{vol}(A \cap (\mathbb{R}^n \setminus V^{\mp}_{P,t})) \;=\; \operatorname{vol}(A) - \operatorname{vol}(A \cap V^{\mp}_{P,t}).$$

since $H_{P,t} = V^+_{P,t} \cap V^-_{P,t}$ is a set of measure zero

We continue with the following claim.

Claim. There exists a function

$$t\colon S^{n-1} \;\to\; \mathbb{R}$$

with the following three properties:

(1) for every $P \in S^{n-1}$ we have $\operatorname{vol}(A_n \cap V^+_{P,t(P)}) = \frac{1}{2}\operatorname{vol}(A_n)$, i.e. the affine hyperplane $H_{P,t(P)}$ bisects A_n,
(2) for every $P \in S^{n-1}$ we have $t(-P) = -t(P)$,
(3) the function t is continuous.

Proof. We first fix $P \in S^{n-1}$. We consider the function

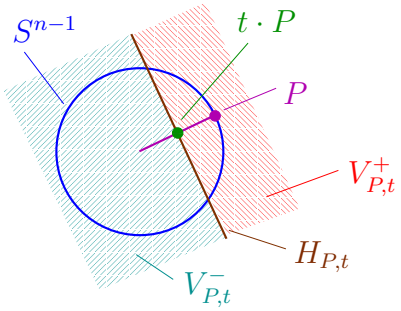
$$\begin{array}{rcl} \mathbb{R} & \to & \mathbb{R}_{\geq 0} \\ t & \mapsto & \operatorname{vol}(A_n \cap V^+_{P,t}). \end{array}$$

This function is continuous[390] and we have

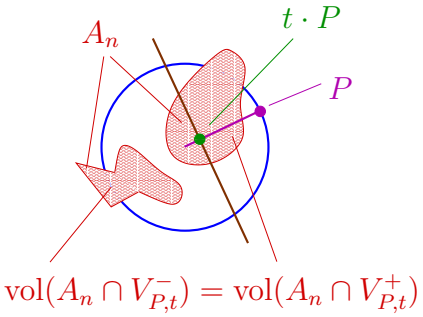
$$\lim_{t\to\infty} \operatorname{vol}(A_n \cap V^+_{P,t}) \underset{\substack{\uparrow \\ \text{Proposition 40.3}}}{=} \operatorname{vol}\Big(\bigcup_{t\in\mathbb{R}} (A_n \cap V^+_{P,t})\Big) = \operatorname{vol}(A_n).$$

and

$$\lim_{t\to-\infty} \operatorname{vol}(A_n \cap V^+_{P,t}) \underset{\substack{\uparrow \\ \text{by (ii)}}}{=} \operatorname{vol}(A_n) - \underbrace{\lim_{t\to-\infty} \operatorname{vol}(A_n \cap V^-_{P,t})}_{=\operatorname{vol}(A_n) \text{ by Proposition 40.3}} = 0.$$



We deduce from the Intermediate Value Theorem that



$$T := \big\{t \in \mathbb{R} \,\big|\, \operatorname{vol}(A_n \cap V^+_{P,t}) = \tfrac{1}{2}\operatorname{vol}(A_n)\big\}$$

is a non-empty set.[391] It is straightforward to see that it is a connected subset of $\mathbb{R}$, i.e. it is an interval. Since $\operatorname{vol}(A_n) > 0$ we know that T is a finite interval. We define

$$t(P) := \tfrac{1}{2}(\inf(T) + \sup(T)).$$

Note that it follows immediately from the definitions that $t(-P) = -t(P)$. Furthermore with some elementary measure theory one can show that the function $S^{n-1} \to \mathbb{R}$ given by $P \mapsto t(P)$ is continuous. We leave the verification of the details to the reader. ⊞

Now we consider the map

$$\begin{array}{rcl} f\colon S^{n-1} & \to & \mathbb{R}^{n-1} \\ P & \mapsto & \big(\operatorname{vol}\big(A_1 \cap V^+_{P,t(P)}\big), \ldots, \operatorname{vol}\big(A_{n-1} \cap V^+_{P,t(P)}\big)\big). \end{array}$$

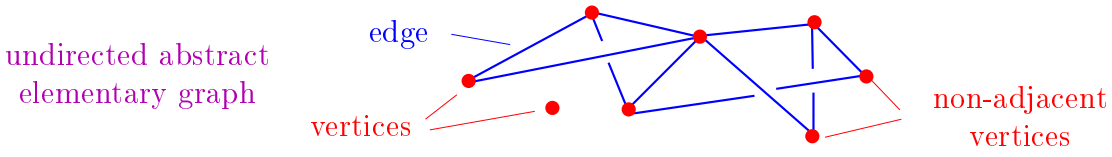
[390] This requires at least a little bit of thought since we do not assume that A is bounded, we only assume it has finite volume. We leave it as a not entirely trivial exercise to prove this statement using basics facts of Lebesgue measures.

[391] One might think that T consists of just a point, but for example if A_n is disconnected, then it can happen that T is in fact an interval that is not just a point.

From the continuity of $t\colon S^{n-1} \to \mathbb{R}$ it follows that f itself is continuous. By the Borsuk-Ulam Theorem 39.8, there exists a point $P \in S^{n-1}$ with $f(P) = f(-P)$. We claim that the affine hyperplane $H_{P,t(P)}$ has the desired property.

By definition of $t(P)$ the affine hyperplane $H_{P,t(P)}$ bisects A_n. Furthermore note that for $i = 1, \ldots, n-1$ we have

$$\operatorname{vol}\left(A_i \cap V^+_{P,t(P)}\right) \underset{\substack{\uparrow \\ \text{since } f(P)=f(-P)}}{=} \operatorname{vol}\left(A_i \cap V^+_{-P,t(-P)}\right) \underset{\substack{\uparrow \\ \text{since } t(-P)=-t(P)}}{=} \operatorname{vol}\left(A_i \cap V^+_{-P,-t(P)}\right) \underset{\substack{\uparrow \\ \text{since } V^+_{P,s}=V^-_{-P,-s}}}{=} \operatorname{vol}\left(A_i \cap V^-_{P,t(P)}\right).$$

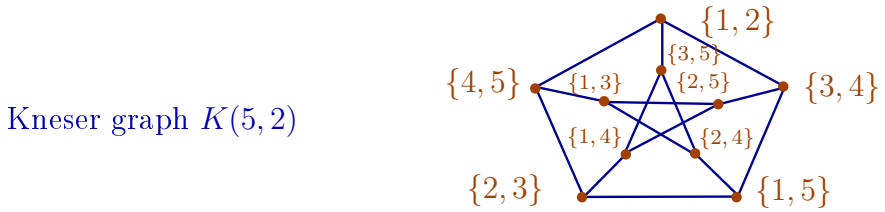


This shows that the affine hyperplane $H_{P,t(P)}$ also bisects $A_1, \ldots, A_{n-1}$. ■

Remark. The proof for the existence of the affine hyperplane that bisects the given sets $A_1, \ldots, A_n$ is non-constructive, in the sense that even with some flexibility in mathematical rigor one cannot turn it into an algorithm that given $A_1, \ldots, A_n$ finds the affine hyperplane that bisects all of the subsets.

40.2. **The chromatic number of Kneser graphs.** In the following we give a definition of an undirected abstract elementary graph.

Definition.

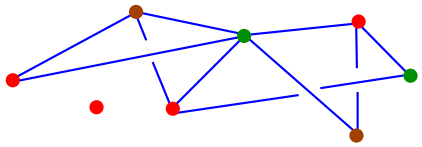


(1) An undirected abstract elementary graph is a pair (V, E) where V is a set, called the vertex set, and a set $E \subset \mathcal{P}(V)$, called the edge set, where each $e \in E$ contains precisely two elements of the vertex set.[392]
(2) Elements of the vertex set are called vertices and elements of the edge set are called edges.
(3) Two vertices v and w are called adjacent if $\{v, w\}$ is an edge.

In this section we only care about the following type of undirected abstract elementary graph.

Definition. Let $n \in \mathbb{N}_0$. The Kneser graph $K(n, k)$ is defined as the undirected abstract elementary graph that is given by the following data:

(1) The vertex set $V(n, k)$ consists of all the k-sets in $\{1, \ldots, n\}$. (A k-set is just a subset with precisely k elements.)
(2) We have an edge between $v, w \in V(n, k)$ precisely if $v \cap w = \varnothing$.



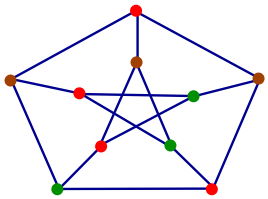
[392] On page 313 we introduced the notion of an undirected abstract graph. The difference is that in an abstract elementary graph we no longer allow loops, i.e. edges where the two endpoints are the same, and we no longer allow multiple edges between two vertices.

Definition. Let $G = (V, E)$ be an undirected abstract elementary graph in the above sense such that V is finite.

(1) Let $c \in \mathbb{N}_0$. A c-vertex coloring of $G = (V, E)$ is a map $\varphi\colon V \to \{1, \dots, c\}$ such that adjacent vertices are assigned different values (colloquially called "colors"). Note that $G = (V, E)$ admits a c-coloring if and only if there exists a decomposition $V = V_1 \sqcup \dots \sqcup V_c$ such that no V_i contains an edge.

(2) The chromatic number of $G = (V, E)$ is the minimal $c \in \mathbb{N}_0$ such that (V, E) admits a c-vertex coloring.

3-coloring



Lemma 40.4. Let $k, d \in \mathbb{N}_0$. The Kneser graph $K(2k + d, k)$ has chromatic number $\chi(K(2k + d, k)) \leq d + 2$.

Proof. As we mentioned above, if we want to show that $\chi(K(n, k)) \leq d+2$ we need to find a decomposition $V(n, k) = V_1 \sqcup \dots \sqcup V_{d+2}$ such that no V_i contains an edge. In other words, we need to find families $V_1, \dots, V_{d+2}$ of disjoint k-sets in $V(n, k)$ with $V(n, k) = V_1 \sqcup \dots \sqcup V_{d+2}$. We do it as follows:

(1) Given $i = 1, \dots, d + 1$ we denote by V_i the k-sets in $\{1, \dots, 2k + d\}$ such that the minimal element is precisely i.

(2) We denote by V_{d+2} all the remaining k-sets. Note that V_{d+2} are precisely the k-sets that are contained in $\{d+2, \dots, 2k+d\}$. Since $\{d+2, \dots, 2k+d\}$ has $2k-1$ elements we see that there are no two disjoint k-sets in $\{d + 2, \dots, 2k + d\}$.

We have thus found the desired decomposition. ■

3-vertex coloring of the Kneser graph $K(5, 2)$:

$V_1 = \{\{1, 2\}, \{1, 3\}, \{1, 4\}, \{1, 5\}\}$

$V_2 = \{\{2, 3\}, \{2, 4\}, \{2, 5\}\}$

$V_3 = \{\{3, 4\}, \{3, 5\}, \{4, 5\}\}$

In 1955 Martin Kneser [**KnesM1955**] conjectured that the inequality in Lemma 40.4 should actually be an equality:

Conjecture 40.5. (Kneser Conjecture 1955[393]**)** For any choice of $k, d \in \mathbb{N}_0$ the Kneser graph $K(2k + d, k)$ has chromatic number $\chi(K(2k + d, k)) = d + 2$.

This purely combinatorial defeated all attempts to prove it using purely combinatorial methods. The conjecture was finally proved in 1978 by László Lovász[394] [**Lov1978**] using the Borsuk-Ulam Theorem 39.8.

[393] Here the naming gets a bit confusing since in topology there is another Kneser Conjecture, see Theorem **??**, which is named after Hellmuth Kneser, the father of Martin Kneser.

[394] László Lovász (*1948) is a Hungarian mathematician. He was awarded the Abels prize in 2021.

Theorem 40.6. (Lovász Theorem 1978) For any $k, d \in \mathbb{N}_0$ the Kneser graph $K(2k+d, k)$ has chromatic number $\chi(K(2k+d,k)) = d+2$.

The proof of the Kneser Conjecture 40.5 we provide is a simplified version of the proof by László Lovász. This simplified proof was found by Josh Greene [**Greene2002**] in 2002. The proof is so charming that it made it in to "the book of proofs" [**AZ2014**].

The proof of the Lovász Theorem 40.6 rests on the following generalization of the Lusternik-Schnirelmann 40.1.

Theorem 40.7. (Generalized Lusternik-Schnirelmann Theorem) Let $A_1, \ldots, A_{n+1}$ be subsets of S^n with $A_1 \cup \cdots \cup A_{n+1} = S^n$. We assume that each of the first n sets $A_1, \ldots, A_n$ is either an open or a closed subset of S^n. Then there exists an $i \in \{1, \ldots, n+1\}$ such that A_i contains a pair of antipodal points.

Proof of the Generalized Lusternik-Schnirelmann Theorem 40.7. Let $A_1, \ldots, A_{n+1}$ be subsets of S^n with $A_1 \cup \cdots \cup A_{n+1} = S^n$. We assume that each of $A_1, \ldots, A_n$ is closed or open in S^n. Without loss of generality we can assume that all $A_1, \ldots, A_n$ are non-empty. [395] In the following we now assume that none of $A_1, \ldots, A_{n+1}$ contains a pair of antipodal points.

Given a non-empty subset A of S^n and $x \in S^n$ we consider again the distance from x to A:

$$d(x, A) \ := \ \inf\{\|x - a\| \mid a \in A\},$$

where $\| - \|$ denotes the usual Euclidean norm on $S^n \subset \mathbb{R}^{n+1}$. By the Distance-to-Subspace the Distance-to-Subspace Lemma 6.2 together with Exercise 1.3 we know that the following two statements hold:

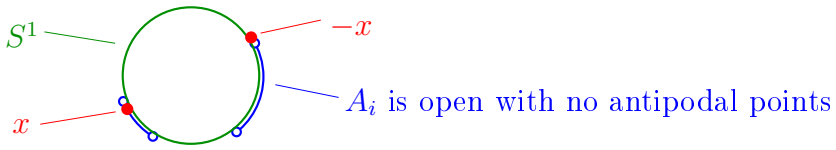
(a) If A is closed, then $d(x, A) = 0$ if and only if $x \in A$.
(b) The map $x \mapsto d(x, A)$ is continuous.

We consider the map

$$\begin{array}{rccl} f\colon & S^n & \to & \mathbb{R}^n \\ & x & \mapsto & (d(x, A_1), \ldots, d(x, A_n)). \end{array}$$

It follows from (b) that this map is indeed continuous. By the Borsuk-Ulam Theorem 39.8 there exists an $x \in S^n$ with $f(x) = f(-x)$. Since A_{n+1} does not contain a pair of antipodal points we see that x or $-x$ is not contained in A_{n+1}. By symmetry we can assume that x is not contained in A_{n+1}. It follows that there exists an $i \in \{1, \ldots, n\}$ such that x lies in A_i. We now distinguish the cases that A_i is closed or open.

(1) First we assume that A_i is closed. It follows immediately from $f(x) = f(-x)$ that $d(-x, A_i) = d(x, A_i) = 0$. Since A_i is closed it follows from (a) that $-x$ lies in A_i. Thus both x and $-x$ lie in A_i. We have obtained a contradiction.
(2) Now we assume that A_i is open. The proof is given by a sequence of little arguments and observations:
   (i) It follows from $f(-x) = f(x)$ and $x \in A_i$ that $d(-x, A_i) = d(x, A_i) = 0$.
   (ii) It follows from (i) and (a) that $-x$ is contained in the closure $\overline{A_i}$ of A_i.
   (iii) Since A_i is open we see that $S^n \setminus (-A_i)$ is a closed subset.



[395] If $A_{n+1} = S^n$ then we are done. Otherwise at least one of the $A_1, \ldots, A_n$ is non-empty, if one of A_i is empty we just replace it with one of the non-empty ones among $A_1, \ldots, A_n$.

(iv) Recall that we assume that A_i has no pair of antipodal points. It follows that $A_i \cap -A_i = \varnothing$, i.e. A_i is contained in $S^n \setminus (-A_i)$.

(v) It follows from (iii) and (iv), together with the definition of the closure, that $\overline{A}_i \subset S^n \setminus (-A_i)$.

(vi) It follows from (ii)-(v) that $-x \in S^n \setminus (-A_i)$.

(vii) It follows from (vi) that $-x \notin -A_i$. This implies that $x \notin A_i$. We have obtained the desired contradiction. ■

We will also need the following elementary lemma.

Lemma 40.8. Given any $d \in \mathbb{N}_0$ and $n \in \mathbb{N}$ there exists a subset $X \subset S^{d+1}$ with n points that is in general position, in the sense that no $d+2$ points of X lie on a hyperplane through the origin.

Proof. [396] Let $d \in \mathbb{N}_0$. We prove the lemma by induction on $n \in \mathbb{N}_0$. The case $n = 0$ is clear. Now suppose that for some $n \in \mathbb{N}_0$ there exists an n-set in S^{d+1} that is in general position. Let V be the union of all hyperplanes in $\mathbb{R}^{d+2}$ that are formed by $(d+1)$-subsets in X. It follows from the Baire Category Theorem 6.16, or alternatively from Propositions 30.2 and 30.3, that $V \subsetneq S^{d+1}$. If we add any point in $S^{d+1} \setminus V$ to X we obtain an $(n+1)$-set in S^{d+1} that is in general position. ■

Proof of the Kneser Conjecture 40.5 aka Lovász Theorem 40.6. Let $k, d \in \mathbb{N}_0$. By Lemma 40.4 it remains to show that $\chi(K(2k+d,k)) \geq d+2$. By Lemma 40.8 there exists a $(2k+d)$-set $X \subset S^{d+1}$ in general position. We now think of $V(2k+d,k)$ as the family of all k-sets in X.

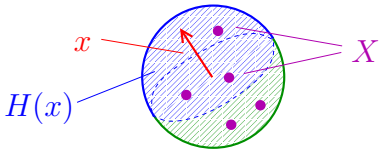
Now let us assume that $\chi(K(2k+d,k)) \leq d+1$. This implies that $K(2k+d,k)$ admits a $(d+1)$-coloring. As we already mentioned in the proof of Lemma 40.4, this means that there exists a decomposition

$$V(2k+d,k) \;=\; \{\text{all } k\text{-sets in } X \;=\; V_1 \sqcup \cdots \sqcup V_{d+1}$$

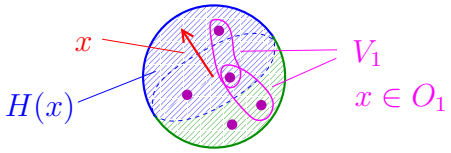
with the following property: for any V_i any two k-sets $A, B \in V_i$ have non-empty intersection. Our goal is to reach a contradiction. Thus we need to show that there exist disjoint k-sets A and B of X that belong to the same V_i.

For $x \in S^{d+1}$ we consider the corresponding open hemisphere

$$H(x) \;:=\; \{y \in S^{d+1} \mid \underbrace{\langle x, y \rangle}_{\text{scalar product}} > 0\}.$$



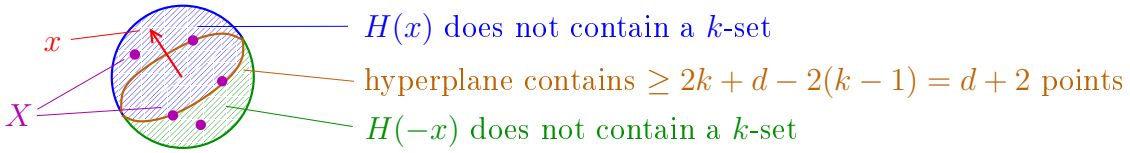
For $i = 1, \ldots, d+1$ we set



$$O_i \;:=\; \{x \in S^{d+1} \mid H(x) \text{ contains a } k\text{-set from } V_i\}.$$

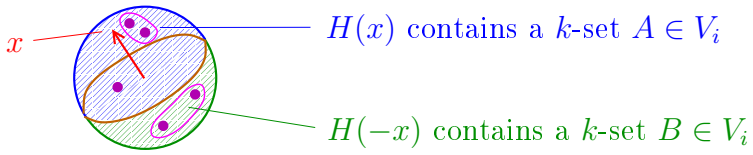
[396] The proof is quite similar to the proof of Lemma 11.18.

It follows easily from the Neighborhood Openness Criterion 1.5 that each O_i is an open subset of S^{d+1}. Evidently the open subsets $O_1, \ldots, O_{d+1}$ together with the closed subset $C := S^n \setminus (O_1 \cup \cdots \cup O_{d+1})$ form a cover of S^{d+1}.



$d = 1$ and $k = 2$

Claim. The subset C does not contain a pair of antipodal points.



Proof. Suppose that $C = S^n \setminus (O_1 \cup \cdots \cup O_{d+1})$ contains a pair of antipodal points x and $-x$. Note that each k-set of X lies in one of the V_i. It follows from this observation and the definition of the O_i's that both open hemispheres $H(x)$ and $H(-x)$ contain less than k points. But this means that at least $d+2$ points lie on $S^{d+1} \setminus (H(x) \cup H(-x))$. But $S^{d+1} \setminus (H(x) \cup H(-x))$ is the intersection of S^{d+1} with a hyperplane. Thus we have obtained a contradiction to the fact that the points on X are in general position. ⊞

Since the O_i are open and since by the claim we know that $C = S^n \setminus (O_1 \cup \cdots \cup O_{d+1})$ does not pair of antipodal points we deduce from the Generalized Lusternik-Schnirelmann Theorem 40.7 that there exists an $i \in \{1, \ldots, d+1\}$ such that O_i contains a pair of antipodal points x and $-x$. We make the following two simple observations:

(1) By definition of $x \in O_i$ there exists a k-set A from V_i with $A \subset H(x)$.
(2) By definition of $x \in O_i$ there exists a k-set B from V_i with $B \subset H(-x)$.

In summary we see that there exist k-sets A and B, both of which lie in V_i, with $A \subset H(x)$ and $B \subset H(-x)$. Since the open hemispheres $H(x)$ and $H(-x)$ are disjoint we see that A and B are disjoint. ■

40.3. **The level of a commutative ring.** In this section we provide an application of the Borsuk-Ulam Theorem 39.8 to algebra. First we have the following definition.

Definition. Let R be a commutative ring. The level $s(R)$[397] of R is defined as the smallest number $n \in \mathbb{N}_0$ such that -1 can be written as the sum of n squares in R. If -1 is not the sum of squares in R, then we define $s(R) = \infty$.

Examples.

[397] The letter "s" stands for the German word "Stufe", which is the original name of "level".

(1) Evidently $s(\mathbb{C}) = 1$ and $s(\mathbb{R}) = \infty$. In fact a commutative ring R with $s(R) = \infty$ is sometimes called *formally real*.
(2) In Exercise 40.4 we will see that $s(\mathbb{Z}_4) = 3$ and $s(\mathbb{Z}[\sqrt{5}\mathrm{i}]) = 2$.

In 1966 Albrecht Pfister [**Pf1965**] proved the following theorem.

Theorem 40.9. (Pfister's Level Theorem) The level of a field is either ∞ or a power of 2.

Proof. The theorem is of course proved in [**Pf1965**]. There are many accounts of the proof, see e.g. also [**Pf1995**, Theorem 3.1.3] and [**Lam2005**, Theorem XI.2.2]. ■

Albrecht Pfister [**Pf1965**] also showed that any power of 2 appears as the level of a field. In 1977 Manfred Knebusch [**Kneb1977**] asked whether every $n \in \mathbb{N}_0$ is the level of some commutative ring. The following theorem, proved by Dai–Lang–Peng [**DLP1980**] gives an affirmative answer.

Theorem 40.10. Given any $n \in \mathbb{N}_0$ there exists a commutative ring R with $s(R) = n$.

Proof. We consider the ring[398] $R = \mathbb{R}[x_1, \ldots, x_n]/(1 + x_1^2 + \cdots + x_n^2)$. Evidently $s(R) \leq n$. We need to show that $s(R) \geq n$. So suppose that $s(R) < n$. This implies that there exist $f_0(x), f_1(x), \ldots, f_{n-1}(x) \in \mathbb{R}[x] = \mathbb{R}[x_1, \ldots, x_n]$ such that

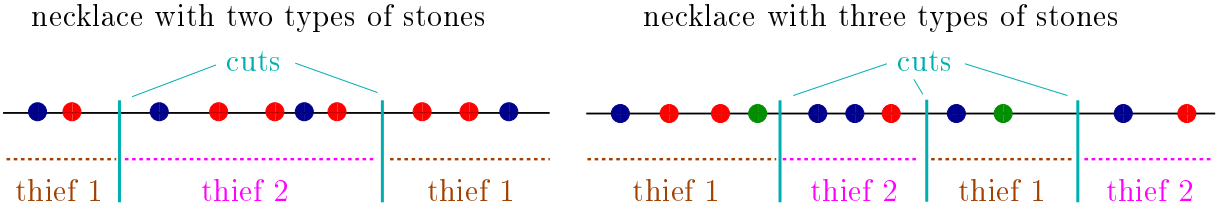
$$(1) \qquad -1 \;=\; f_1(x)^2 + \cdots + f_{n-1}(x)^2 + f_0(x) \cdot (1 + x_1^2 + \cdots + x_n^2) \;\in\; \mathbb{R}[x_1, \ldots, x_n].$$

Let $j \in \{0, \ldots, n-1\}$. Since $f_j(x)$ is a real polynomial we can write $f_j(\mathrm{i}x) = p_j(x) + \mathrm{i}q_j(x)$ where $p_j(x)$ is an even real polynomial and $q_j(x)$ is an odd real polynomial. Thus if we plug $\mathrm{i}x$ into Equality (1) and if we compare the real parts we obtain the following equality:

$$(2) \qquad -1 \;=\; \sum_{j=1}^{n-1} (p_j(x)^2 - q_j(x)^2) + p_0(x) \cdot (1 - x_1^2 - \cdots - x_n^2).$$

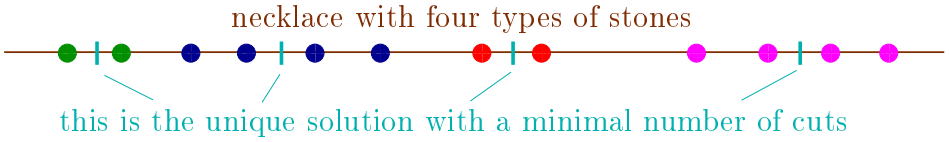
Next we consider the map $Q := (q_1, \ldots, q_{n-1})\colon \mathbb{R}^n \to \mathbb{R}^{n-1}$. Since the polynomials $q_1, \ldots, q_{n-1}$ are odd we see that for every $a \in S^{n-1}$ we have $Q(-a) = -Q(a)$. Furthermore, by the Borsuk-Ulam Theorem 39.8 there exists an $a = (a_1, \ldots, a_n) \in S^{n-1}$ with $Q(-a) = Q(a)$. Note that it follows from the above symmetry of Q that we have $Q(a) = 0$. Now we see that

$$-1 \;\underset{\text{by Equality (2)}}{\uparrow}\; \sum_{j=1}^{n-1} (p_j(a)^2 - q_j(a)^2) + p_0(a) \cdot \overbrace{(1 - a_1^2 - \cdots - a_n^2)}^{=\,1 \text{ since } a \in S^{n-1}} \;\underset{\text{since } Q(a) = 0 \text{ and } a \in S^{n-1}}{\uparrow}\; \sum_{j=1}^{n-1} p_j(a)^2.$$



Since the right-hand side is non-negative we have thus obtained a contradiction. ■

Remark.



(1) The proof of Theorem 40.10 that we provide is rather ad hoc. One can also introduce a general notion of a level $s(X)$ of a topological space and use it to prove Theorem 40.10. We refer to [**Pf1995**, Chapter 3] for details.
(2) In the proof of Theorem 40.10 we only need to apply the Borsuk-Ulam Theorem 39.8 to maps that are given by polynomials. In this setting a purely algebraic proof of the Borsuk-Ulam Theorem 39.8 was given by Manfred Knebusch [**Kneb1982**].

[398] Note that standard algebra, see e.g. [**Pf1995**, p. 45], shows that R is actually even a domain.

40.4. **The Necklace Theorem.** We conclude this chapter with another, fun consequence of the Borsuk-Ulam Theorem. As in some of the earlier sections this application is again far-removed from what one would usually consider to be the realm of topology.
The setting is the following: Two thieves steal an open necklace with precious stones of k different types. Conveniently enough, of each type of stone there is an even number. The thieves want to cut the string of the open necklace such that they can distribute the resulting pieces in such a way that both thieves obtain the same number of stones of each type. The question is, what is the minimal number of cuts necessary? In the figure below we show two necklaces, one with two types of stones and one with three types of stones. Furthermore we show possible cuts to evenly distribute the stones.

Another open necklace is shown in the figure below. In this particular example the k different types of stones are grouped together. It is pretty clear that one will need at least k cuts to distribute the stones. It turns out that this is the worst case, more precisely, it

turns out that any string of k different types of stones can be distributed evenly using at most k cuts. The following theorem is a formalization of that statement.

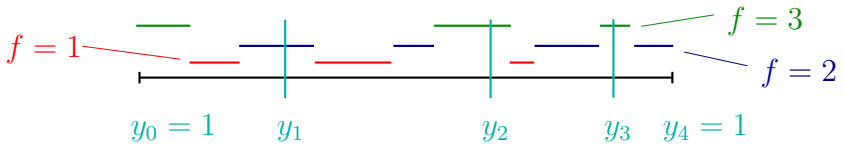
Theorem 40.11. (Necklace Theorem) Let $S_1, \dots, S_k$ be disjoint finite subsets of the interval $[0,1)$ such that each subset S_i has an even number of elements. There exists a $d \in \{0, \dots, k\}$ and $0 = z_0 \leq z_1 \leq \cdots \leq z_d \leq z_{d+1} = 1$ such that for each "color" $c \in \{1, \dots, k\}$ we have

$$\underbrace{\sum_{i \text{ even}} \#([z_i, z_{i+1}) \cap S_c)}_{\substack{\text{number of } c\text{-colored pieces} \\ \text{in the even intervals}}} = \underbrace{\sum_{i \text{ odd}} \#([z_i, z_{i+1}) \cap S_c)}_{\substack{\text{number of } c\text{-colored pieces} \\ \text{in the odd intervals}}} .$$

Remark.

(1) The Necklace Theorem 40.11 was first formulated and proved by Charles Goldberg and Douglas West [**GW1985**] in 1985 using topological methods. The proof we give was found shortly afterwards by Noga Alon and Douglas West [**AW1986**].
(2) A topology-free proof of the Necklace Theorem 40.11 was found in 2008 by Frédéric Meunier [**Meu2008**].
(3) The Necklace Theorem 40.11 has been generalized by Noga Alon [**Nog1987**], again using topological methods, to the case of more than two thieves. It seems like there is no known proof for that more general statement, that does not rely on topology.

(4) The proofs of the Necklace Theorem 40.11 and of the Continuous Necklace Theorem 40.12 are both nicely animated in the following video:



`https://www.youtube.com/watch?v=yuVqxCSsE7c&t=868s`

The Necklace Theorem 40.11 is a priori a discrete problem, far removed from the world of topological spaces. In fact the proof consists of two steps, first we will use the Borsuk-Ulam Theorem 39.8 to prove a "continuous analogue" of the Necklace Theorem 40.11. Afterwards we will show how we can reduce the "discrete Necklace Theorem" from the "continuous Necklace Theorem". Since we will not make use of any of the results of this section we will feel free to use slightly more informal language than usual.
Without further ado, here is the promised continuous analogue of the Necklace Theorem 40.11.

Theorem 40.12. (Continuous Necklace Theorem) Let $f\colon [0,1] \to \{1,\dots,k\}$ be a function[399] such that each preimage $f^{-1}(c)$ is a measurable set (e.g. a union of finitely many intervals). There exists a $d \in \{0,\dots,k\}$ and $0 = y_0 \leq y_1 \leq \dots < y_d \leq y_{d+1} = 1$ such that for each "color" $c \in \{1,\dots,k\}$ we have

$$\underbrace{\sum_{i \text{ even}} \operatorname{vol}\big([y_i, y_{i+1}) \cap f^{-1}(c)\big)}_{\substack{\text{total length of } c\text{-colored} \\ \text{segments in the even intervals}}} = \underbrace{\sum_{i \text{ odd}} \operatorname{vol}\big([y_i, y_{i+1}) \cap f^{-1}(c)\big)}_{\substack{\text{total length of } c\text{-colored} \\ \text{segments in the odd intervals}}}.$$

The same statement also holds for functions f which are defined on $[0,1)$.

Proof. We adopt the following notation: given $(w_0,\dots,w_k) \in S^k$ we set $x_0 = 0$ and for $i = 1,\dots,k$ we write $x_i := w_0^2 + \dots + w_{i-1}^2$. We make the following observation which is the key to the subsequent proof:

> Let $(w_0,\dots,w_k) \in S^k$. We note that $x_0 = 0 \leq x_1 \leq \dots \leq x_k \leq x_{k+1} = 1$. Thus any point in S^k corresponds to a splitting of the interval $[0,1)$ into $k+1$ (possibly empty) intervals. In fact, if we remember the signs of the w_i, then we obtain a way to assign each interval to one of the two thieves, say we award $[x_i, x_{i+1})$ to thief 1 if $w_i < 0$ and to thief 2 if $w_i > 0$. Thus the set of splittings of the interval corresponds to the topological space S^k.

For $c = 1,\dots,k$ we consider the following map:

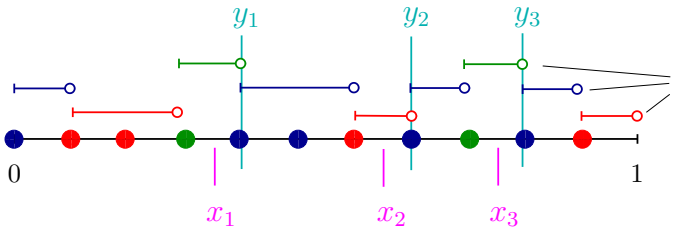
$$\begin{aligned} g_c\colon S^k &\to \mathbb{R} \\ (w_0,\dots,w_k) &\mapsto \sum_{i \text{ with } w_i > 0} \operatorname{vol}\Big(\big[\underbrace{x_i, x_{i+1}}_{\substack{\uparrow \\ \text{here we use the above definition of } x_0,\dots,x_{k+1} \\ \text{as determined by } w_0,\dots,w_k}}\big) \cap f^{-1}(c)\Big). \end{aligned}$$

[399] Evidently for once the convention that all maps are continuous does not apply.

We leave it to the meticulous reader to show, using standard properties of the Lebesgue-measure, that the map g_c is actually continuous.[400]

Next we combine all these maps and we obtain a map $g = (g_1, \dots, g_k)\colon S^k \to \mathbb{R}^k$. By the Borsuk-Ulam Theorem 39.8 there exists a point $(w_0, \dots, w_k) \in S^k$ such that $g(-w_0, \dots, -w_k) = g(w_0, \dots, w_k)$. This just means that for each $c \in \{1, \dots, k\}$ we have

$$\underbrace{\sum_{i \text{ with } w_i < 0} \operatorname{vol}\big([x_i, x_{i+1}) \cap f^{-1}(c)\big)}_{=g_c(-w_0,\dots,-w_k)} = \underbrace{\sum_{i \text{ with } w_i > 0} \operatorname{vol}\big([x_i, x_{i+1}) \cap f^{-1}(c)\big)}_{=g_c(w_0,\dots,w_k)}.$$



Finally, we consider the numbers $x_0 \le x_1 \le \dots \le x_{k+1} = 1$. Now we just need to combine adjacent intervals for which the w_i's have the same sign. More precisely, iteratively we remove each x_i for which $w_i \ge 0$ and $w_{i+1} \ge 0$ and we remove each x_i for which $w_i \le 0$ and $w_{i+1} \le 0$. It is now fairly elementary to verify that the remaining numbers, let us call them $0 = y_0 < y_1 < \dots < y_d < y_{d+1} = 1$, have the desired properties. ∎

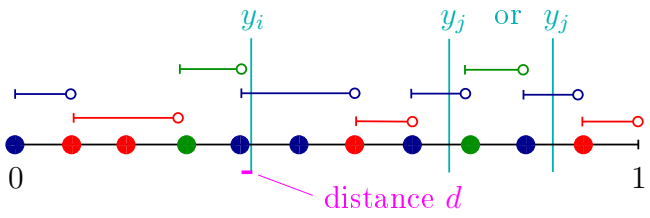
Proof of the Necklace Theorem 40.11. Let $S_1, \dots, S_k$ be disjoint finite subsets of the interval $[0, 1]$ such that each S_i has an even number of elements. Evidently we can assume that $S_1 \cup \dots \cup S_k \neq \varnothing$. We set $s := \#(S_1 \cup \dots \cup S_k)$. It is straightforward to see that without loss of equality we can assume that the points break $[0, 1]$ into intervals of the same lengths $\frac{1}{s}$. More precisely, we can assume that $\bigcup_{i=1}^{k} S_i = \{\frac{i}{s} \mid i = 0, \dots, s-1\}$. Now let $f\colon [0, 1) \to \{1, \dots, k\}$ be the function which is uniquely determined by the property that for each $c \in S_i$ we have $f(x) = i$ for $x \in [c, c + \frac{1}{s})$. By the Continuous Necklace Theorem 40.12 there exists a $d \in \{0, \dots, k\}$ and $0 = y_0 \le y_1 \le \dots \le y_d \le y_{d+1} = 1$ such that for each $c \in \{1, \dots, k\}$ we have

$$(*) \qquad \sum_{i \text{ even}} \operatorname{vol}\big([y_i, y_{i+1}) \cap f^{-1}(c)\big) = \sum_{i \text{ odd}} \operatorname{vol}\big([y_i, y_{i+1}) \cap f^{-1}(c)\big).$$

If each of the y_i lies in the "lattice" $L := \{\frac{i}{s} \mid i = 0, \dots, s\}$, then we can set $z_i := y_i - \frac{1}{2s}$, $i = 1, \dots, d$ and we are done. (This setting is shown in the figure below.) Thus it remains to prove the following claim.

necklace with three types of stones

Claim. We can find $0 = y_0 \le y_1 \le \dots \le y_d \le y_{d+1} = 1$ which satisfy $(*)$ and such that each y_i lies in $L = \{\frac{i}{s} \mid i = 0, \dots, s\}$.



Proof. We prove the claim by induction on the number of y_i that do not lie in the subset $L = \{\frac{i}{s} \mid i = 0, \dots, s\}$. Throughout the proof of the claim we use the following slightly

[400] The fact that we take the sum over all i with $w_i > 0$ might make the reader slightly nervous. But note that for $w_i = 0$ we have $x_{i+1} = x_i$, thus $\operatorname{vol}([x_i, x_{i+1}) \cap f^{-1}(c)) = 0$.

non-standard notation: given $y \in [0,1]$ we define $\lfloor y \rfloor$ and $\lceil y \rceil$ as the result of rounding y down and up to the closest point in L. More precisely, we set $\lfloor y \rfloor := \max\{l \in L \,|\, l \leq y\}$ and we set $\lceil y \rceil := \min\{l \in L \,|\, y \leq l\}$. So suppose there does exist some y_i that does not lie in L. In this case we perform the following three steps:

(1) Among all y_i which do not lie in L we pick a y_i which is closest to a point in L. Without loss of generality we can assume that i is odd.
(2) We define d to be the distance of y_i to some point in L. In other words, if the point on L that is closest to y_i is to the left, then we set $d := y_i - \lfloor y_i \rfloor$. Otherwise we set $d := \lceil y_i \rceil - y_i$.
(3) It follows fairly easily from $(*)$ and the hypothesis that S_c has an even number of elements that there exists a $j \neq i$ such that $f(y_j) = c$ and such that $y_j \notin L$. We distinguish two cases:
   (a) If j is even, then among those we pick the one with a lowest value for $y_j - \lfloor y_j \rfloor$. We replace y_i by $y_i - d \in L$ and we replace y_j by $y_j - d$.
   (b) If j is odd, then among those we pick the one with a lowest value for $\lceil y_j \rceil - y_j$. We replace y_i by $y_i - d \in L$ and we replace y_j by $y_j + d$.

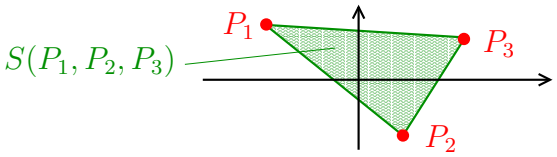
One can easily verify that these new numbers still have all the required properties, except that now y_i also lies in L. By induction we are now done. ■

Exercises for Chapter 40.

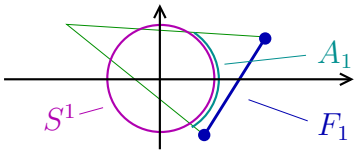
Exercise 40.1. Give a proof of the Lusternik-Schnirelmann Theorem 40.1 for $n = 1$ just using methods from real analysis. More precisely, let A, B be two closed subsets of S^1 with $A \cup B = S^1$. Show, just using methods from your real analysis course, that A or B contains a pair of antipodal points.

Exercise 40.2. Let $n \in \mathbb{N}$ and let $P_1, \ldots, P_{n+1}$ be $n+1$ points in $\mathbb{R}^n$ that are in general position, i.e. that are not contained in a hyperplane of $\mathbb{R}^n$. We consider the corresponding "simplex"

$$S(P_1, \ldots, P_{n+1}) \;:=\; \left\{ \sum_{i=1}^{n+1} t_i \cdot P_i \;\middle|\; \sum_{i=1}^{n+1} t_i = 1 \text{ and } t_1, \ldots, t_{n+1} \in \mathbb{R}_{\geq 0} \right\}.$$



For $i = 1, \ldots, n+1$ we denote by F_i the "i-th face" of $S(P_1, \ldots, P_{n+1})$, i.e. the subspace that is given by setting $t_i = 0$.



(1) Show that $\underbrace{\partial S(P_1, \ldots, P_{n+1})}_{\text{subspace of } \mathbb{R}^n} = \bigcup_{i=1}^{n+1} F_i$.

(2) Now assume that we have picked $P_1, \dots, P_{n+1}$ such that the origin 0 lies in the interior of $S(P_1, \dots, P_{n+1})$. For $i = 1, \dots, n+1$ we set

$$A_i \;:=\; S^{n-1} \cap \{\lambda \cdot v \,|\, v \in F_i \text{ and } \lambda \in \mathbb{R}_{\geq 0}\}.$$

Show that each A_i is closed, show that $S^{n-1} = A_1 \cup \dots \cup A_{n+1}$ and show that no A_i contains a pair of antipodal points.

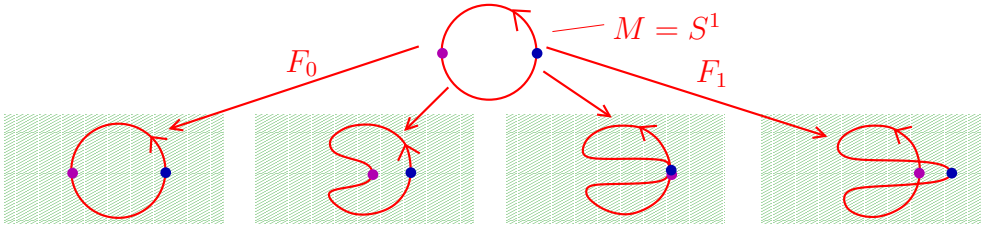
Exercise 40.3. Let $k \in \mathbb{N}$ and let $l \in \{1, \dots, k-1\}$. Furthermore let $f\colon S^k \to \mathbb{R}^l$ be a map with $f(x) = -f(x)$ for all $x \in S^k$. Show that there exists an $x \in S^k$ with $f(x) = 0$.

Exercise 40.4. Given a commutative ring R we denote by $s(R)$ the level of R as defined on page 945.

(a) Show that $s(\mathbb{Z}_4) = 3$.
(b) Show that $s(\mathbb{Z}[\sqrt{5}\mathrm{i}]) = 2$.

Exercise 40.5. We consider the string of jewels shown in the figure below. Use four cuts to distribute the jewels evenly.

Exercise 40.6. We consider again the setting of the Continuous Necklace Theorem 40.12. More precisely we are given a map $f\colon [0,1] \to \{1, \dots, k\}$ such that each preimage $f^{-1}(c)$ is a measurable set. For each "color" $c \in \{1, \dots, k\}$ let $y_c \in [0,1]$ be such that we have the equality $\mathrm{vol}\left(f^{-1}(c) \cap [0, y_c]\right) = \mathrm{vol}\left(f^{-1}(c) \cap [y_c, 1]\right)$. Do these points $y_1, \dots, y_k$, after ordering them, necessarily satisfy the conclusion of the Continuous Necklace Theorem 40.12?



41. Regular homotopies and the Whitney-Graustein Theorem

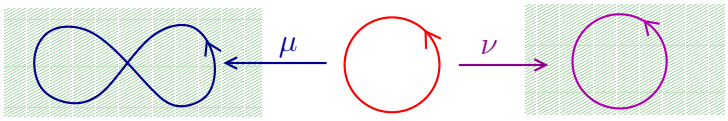
In this chapter we will take a short detour from explaining the key concepts of differential topology. Namely we will introduce and study the concept of regular homotopies. We will use the notion of the degree of a self-map of S^1 to prove the Whitney-Graustein Theorem 41.7 which gives a complete classification of immersions of S^1 into $\mathbb{R}^2$ up to regular homotopies. We will not make use of the results of this chapter.

41.1. **Regular homotopies.** On page 651 we introduced the notion of an immersion. A smooth homotopy of immersions is called a regular homotopy. More precisely, we have the following definition.

Definition. Let M and N be smooth manifolds. We assume that $\partial N = \varnothing$.

(1) A map $f\colon M \to N$ is called an immersion if f is smooth and if for each $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is a monomorphism.
(2) A regular homotopy is a smooth map $F\colon M \times [0,1] \to N$ such that each $F_t\colon M \to N$ is an immersion.
(3) We say that two immersions $f_0, f_1\colon M \to N$ are regularly homotopic if there exists a regular homotopy $F\colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$.

regular homotopy $F\colon S^1 \times [0,1] \to \mathbb{R}^2$



Lemma 41.1. Let M and N be smooth manifolds. We assume that $\partial N = \varnothing$. Being regularly homotopic is an equivalence relation on the set of immersions $M \to N$.

Proof. The proof of the lemma is basically identical to the proof of the Smooth Isotopy Transitivity Proposition 33.3. ■

In the following we restrict ourselves to immersions $S^1 \to \mathbb{R}^n$. First note that any two smooth maps $\gamma, \delta\colon S^1 \to \mathbb{R}^n$ (in particular any two immersions) are smoothly homotopic. For example such a smooth homotopy is given by the map

$$\begin{array}{rcl} F\colon S^1 \times [0,1] & \to & \mathbb{R}^n \\ (z,t) & \mapsto & \gamma(z)\cdot t + \delta(z)\cdot(1-t). \end{array}$$

In Exercise 41.1 we will see that if $n \geq 3$, then any two immersions $S^1 \to \mathbb{R}^n$ are regularly homotopic. This raises the natural question, whether any two immersions $S^1 \to \mathbb{R}^2$ are also regularly homotopic.

are these two immersions regularly homotopic?

In the following we will address this question. Throughout the following discussion we will adopt the following convention and notation.

Convention. We will use the natural isomorphism from the Tangent Space-Isomorphism Proposition 23.16 as an excuse not to distinguish in the notation between the physical tangent spaces and the abstract tangent spaces of S^1 and $\mathbb{R}^n$. Furthermore we will use the Differential-equals-Differential Lemma 23.4 to go back and forth freely between the different notions of differentials.

Definition.

(1) Given a smooth map $f\colon \mathbb{R} \to \mathbb{R}^n$ and $t \in \mathbb{R}$ we write, following the discussion on page 536, $f'(t) := \mathrm{D}\, f_t \cdot 1 \in \mathbb{R}^n$.[401]

(2) Let $r \in \mathbb{R}$. We say that a map $f\colon \mathbb{R} \to X$ is r-periodic if for every $x \in \mathbb{R}$ we have $f(x+r) = r$.

(3) We consider the 2π-periodic map

$$\begin{array}{rccc} \Xi\colon & \mathbb{R} & \to & S^1 \\ & s & \mapsto & \exp(\mathrm{i}s). \end{array}$$

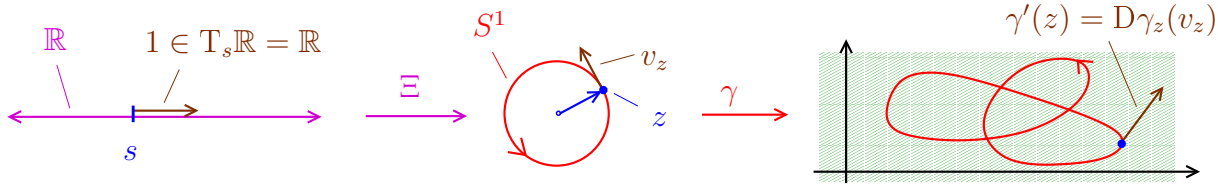
(4) Let $z \in S^1$. We write

$$v_z := \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \cdot z \underset{\uparrow}{=} \mathrm{i} \cdot z.$$

under the usual identification $\mathbb{R}^2 = \mathbb{C}$

We make the following two observations:

(a) The vector v_z is the unique vector of length one in $\mathrm{T}_z S^1$ that defines a positive basis of $\mathrm{T}_z S^1$ with respect to the standard orientation of S^1 that we introduced on page 681.



(b) For any $s \in \mathbb{R}$ we have $\mathrm{D}\Xi_s(1) = v_{\Xi(s)}$.

(5) Given a smooth map $\gamma\colon S^1 \to \mathbb{R}^n$ and given $z \in S^1$ we define

$$\gamma'(z) := \mathrm{D}\gamma_z(v_z) \in \mathrm{T}_z S^1,$$

where $\mathrm{D}\gamma_z\colon \mathrm{T}_z S^1_z \to \mathrm{T}_{\gamma(z)}\mathbb{R}^n = \mathbb{R}^n$ denotes the differential of γ at z.

(6) We say that a smooth map $\gamma\colon S^1 \to \mathbb{R}^n$ has unit speed if $\|\gamma'(z)\| = 1$ for all $z \in S^1$.

When studying maps $\gamma\colon S^1 \to X$ it is often convenient to replace such a map by the map $\gamma \circ \Xi\colon \mathbb{R} \to X$, since $\mathbb{R}$ is a more familiar and much easier domain to work with. The following lemma summarizes in our context the relationship between the maps γ and $\gamma \circ \Xi$.

Lemma 41.2.

(1) Let $\gamma\colon S^1 \to \mathbb{R}^n$ be a map.

(a) The map $\gamma \circ \Xi\colon \mathbb{R} \to \mathbb{R}^n$ is 2π-periodic.

[401] Here $1 \in \mathrm{T}_t\mathbb{R} = \mathbb{R}$.

(b) The map $\gamma\colon S^1 \to \mathbb{R}^n$ is smooth if and only if $\gamma \circ \Xi\colon \mathbb{R} \to \mathbb{R}^n$ is smooth.

We now assume that γ is smooth. Then the following statements hold:

(c) For any $t \in \mathbb{R}$ we have $\gamma'(\Xi(t)) = (\gamma \circ \Xi)'(t)$.

(d) The map $\gamma\colon S^1 \to \mathbb{R}^n$ is an immersion if and only if $(\gamma \circ \Xi)'(t) \neq 0$ for all $t \in \mathbb{R}$.

(2) (a) If $\widetilde{\rho}\colon \mathbb{R} \to \mathbb{R}^n$ is a (smooth) 2π-periodic map, then there exists a unique (smooth) map $\rho\colon S^1 \to \mathbb{R}^n$ with $\widetilde{\rho} = \rho \circ \Xi$.

(b) If $\widetilde{F}\colon \mathbb{R} \times [0,1] \to \mathbb{R}^n$ is a smooth homotopy such that each $\widetilde{F}_t$ is 2π-periodic map, then there exists a unique smooth homotopy $F\colon S^1 \times [0,1] \to \mathbb{R}^n$ with $\widetilde{F} = F \circ (\Xi \times \mathrm{id}_{[0,1]})$.

Proof.

(1) (a) This statement is clear.

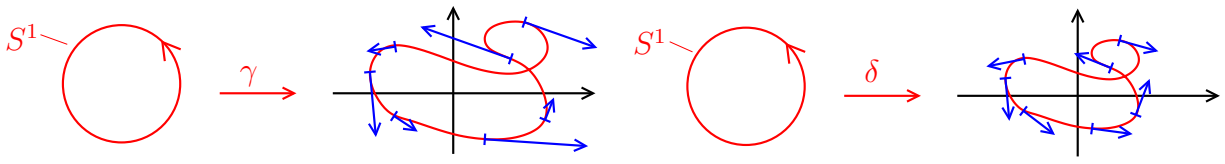
(b) This statement follows from the Smooth Pasting Proposition 19.23 (3) since Ξ is a local diffeomorphism.

(c) Given $t \in \mathbb{R}$ we have

$$\gamma'(\Xi(t)) \underset{\uparrow}{=} (\mathrm{D}\gamma_{\Xi(t)})(v_{\Xi(t)}) \underset{\uparrow}{=} \overbrace{\mathrm{D}(\gamma \circ \Xi)_t(1)}^{\text{differential}} \underset{\uparrow}{=} \overbrace{\mathrm{D}(\gamma \circ \Xi)_t \cdot 1}^{2 \times 1\text{–matrix}} \underset{\uparrow}{=} (\gamma \circ \Xi)'(t).$$

by definition and since $v_{\Xi(t)} = (\mathrm{D}\Xi_t)(1)$ — Tangent Space-Functor Proposition 23.10 (2b) — Lemma 23.4 — by definition

(d) This statement is an immediate consequence of (1c).



(2) (a) By the Smooth Map-Descends-to-Quotient Corollary 19.33 we know that $\widetilde{\rho}$ descends to a smooth map $\mathbb{R}/2\pi\mathbb{Z} \to \mathbb{R}^n$. The statement now follows from the fact, which we basically proved in Torus-as-Quotient Lemma 19.34, that the following map is a diffeomorphism:

$$\begin{array}{ccc} \mathbb{R}/2\pi\mathbb{Z} & \to & S^1 \\ [t] & \mapsto & \Xi(t) \end{array}$$

(b) The proof of Statement (b) is basically the same as the proof of Statement (a). ■

We start out our discussions of immersions of S^1 into $\mathbb{R}^n$ with the following proposition.

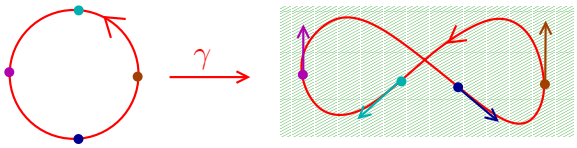
Proposition 41.3. Every immersion $\gamma\colon S^1 \to \mathbb{R}^n$ is regularly homotopic to an immersion $\delta\colon S^1 \to \mathbb{R}^n$ of unit speed.

Proof. The proposition is proved via a suitable reparametrization and rescaling of the immersion γ. We postpone the full proof of Proposition 41.3, with all the technical details, to Section 41.2. ■

Lemma 41.4. Given any immersion $\gamma\colon S^1 \to \mathbb{R}^2$ the following map is smooth:

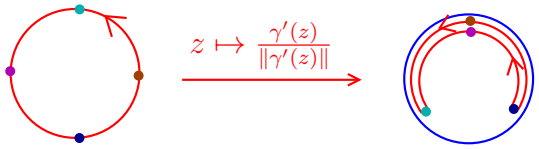
$$\begin{array}{ccc} S^1 & \to & S^1 \\ z & \mapsto & \dfrac{\gamma'(z)}{\|\gamma'(z)\|} \end{array}$$

Proof. Given $z \in S^1$ we set $g(z) := \frac{\gamma'(z)}{\|\gamma'(z)\|}$. We need to show that the map $g\colon S^1 \to S^1$ is smooth. As usual let $\Xi\colon \mathbb{R} \to S^1$ be the map that is given by $\Xi(s) = \exp(\mathrm{i}s)$. By Lemma 41.2 (1b) it suffices to show that $g \circ \Xi\colon \mathbb{R} \to S^1$ is smooth. In fact it suffices to show that the map $s \mapsto \gamma'(\Xi(s))$ is smooth. Note that for any $s \in \mathbb{R}$ we have



$$\gamma'(\Xi(s)) \overset{\text{Lemma 41.2 (1c)}}{\underset{\downarrow}{=}} (\gamma \circ \Xi)'(s) \overset{\text{by definition}}{\underset{\downarrow}{=}} \underbrace{\mathrm{D}(\gamma \circ \Xi)_s}_{2 \times 1\text{–matrix}} \cdot 1.$$

Since γ and Ξ are smooth we know that $\gamma \circ \Xi\colon \mathbb{R} \to \mathbb{R}^2$ is smooth, which implies, by definition, that the entries of the differential $\mathrm{D}(\gamma \circ \Xi)_s \in \mathrm{M}(2 \times 1, \mathbb{R})$ are smooth in s. This implies the desired statement. ∎



Lemma 41.4 allows us to introduce the following definition.

Definition. Given an immersion $\gamma\colon S^1 \to \mathbb{R}^2$ we define its rotation number as follows:[402][403]

$$\rho(\gamma) := \deg \begin{pmatrix} S^1 & \to & S^1 \\ z & \mapsto & \frac{\gamma'(z)}{\|\gamma'(z)\|} \end{pmatrix}.$$

immersion γ

the corresponding map $z \mapsto \frac{\gamma'(z)}{\|\gamma'(z)\|}$ is null-homotopic, hence $\rho(\gamma) = 0$

Remark. The rotation number of an immersion $\gamma\colon S^1 \to \mathbb{R}^2$ is sometimes also called the *turning number*, see [**BG1988**, Chapter 9.4] or *rotation index*, see [**doC2016**, p. 399] and[**MoR2009**, p. 329].

Lemma 41.5. Let $n \in \mathbb{Z} \setminus \{0\}$. With the usual identification $\mathbb{R}^2 = \mathbb{C}$ we have

$$\rho \begin{pmatrix} S^1 & \to & \mathbb{C} \\ z & \mapsto & z^n \end{pmatrix} = n.$$

Proof. Let $n \in \mathbb{Z} \setminus \{0\}$. We denote by $\theta\colon S^1 \to \mathbb{C}$ the map that is given by $z \mapsto z^n$. Furthermore, very carefully, we denote by $\Theta\colon \mathbb{C} \to \mathbb{C}$ the map that is given by $z \mapsto z^n$.

[402] Since γ is an immersion we know that for every $z \in S^1$ we have $\gamma'(z) \neq 0$. This implies that it actually makes sense to normalize $\gamma'(z)$ to length one.

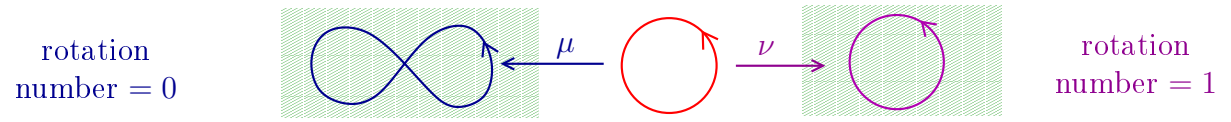
[403] The map $z \mapsto \frac{\gamma'(z)}{\|\gamma'(z)\|}$ is closely related to the Gauß map that we will introduce on page 1036.

Note that

$$\theta'(z) \overset{\text{definition of } \theta'(z)}{=} \mathrm{D}\theta_z(v_z) \overset{\text{since } \Theta|_{S^1}=\theta}{=} \underbrace{\mathrm{D}\Theta_z}_{\text{Differential}}(v_z) \overset{\text{Differential-equals-Differential Lemma 23.4}}{=} \underbrace{\mathrm{D}\Theta_z}_{2\times 2\text{-matrix}} \cdot v_z$$

$$\overset{\text{by viewing } \Theta \text{ as a holomorphic map, see the Smooth-Complex Differentiability Proposition 32.3, and using the definition of } v_z}{=} \Theta'(z)\cdot \mathrm{i}z = n\cdot z^{n-1}\cdot \mathrm{i}z = n\cdot z^n\cdot \mathrm{i} = n\cdot z^n\cdot \mathrm{i}.$$

Thus we see that



$$\rho(\theta) \overset{\text{by the above, since } |n\cdot z^n\cdot \mathrm{i}| = n}{=} \deg \begin{pmatrix} S^1 & \to & S^1 \\ z & \mapsto & \mathrm{i}\cdot z^n \end{pmatrix} \overset{\text{same calculation as in Lemma 38.9}}{=} n.$$

■

The following proposition explains why we are interested in the rotation number.

Proposition 41.6. Let $\alpha, \beta\colon S^1 \to \mathbb{R}^2$ be two immersions. If α and β are regularly homotopic, then the rotation numbers agree.

Example. We return to the two immersions μ and ν that we encountered in the figure on page 952. By Lemma 41.5 and direct inspection we see that the rotation numbers are 0 and 1. It follows from Proposition 41.6 that these two immersions are not regularly homotopic.

the two immersions have different rotation numbers, thus they are not regularly homotopic

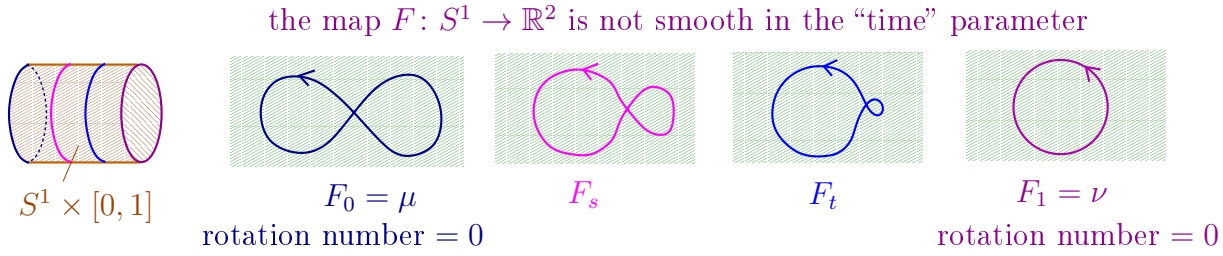
Proof. Let $F\colon S^1 \times [0,1] \to S^1$ be a regular homotopy with $F_0 = \alpha$ and $F_1 = \beta$. It follows immediately from the Degree Homotopy Invariance Theorem 38.3, together with the definition of the winding number, that it suffices to prove the following claim.

Claim. The map

$$\begin{array}{rcl} G\colon S^1 \times [0,1] & \to & S^1 \\ (z,t) & \mapsto & \dfrac{F_t'(z)}{\|F_t'(z)\|} \end{array}$$

is a smooth map, i.e. it is a smooth homotopy.

Proof. Not surprisingly the proof of the claim shares many features with the proof of Lemma 41.4. As before we consider the map $\Xi\colon \mathbb{R} \to S^1$ that is given by $s \mapsto \exp(\mathrm{i}s)$. Note that $\Xi \times \mathrm{id}_{[0,1]}\colon \mathbb{R}\times[0,1] \to S^1 \times [0,1]$ is a local diffeomorphism. Thus it follows from the Smooth Pasting Proposition (3) that it suffices to show that $G \circ \Xi\colon \mathbb{R}\times[0,1] \to S^1$ is smooth. In fact it suffices to show that the map



$$\begin{array}{rcl} \mathbb{R}\times[0,1] & \to & \mathbb{R}^2 \setminus \{(0,0)\} \\ (s,t) & \mapsto & F_t'(\Xi(s)) \end{array}$$

is smooth. Note that it follows from Lemma 41.2 that for any $s \in \mathbb{R}$ and $t \in [0,1]$ we have

$$\begin{array}{lcll} & \text{Lemma 41.2 (1c)} & \text{since } F_t \circ \Xi = (F \circ (\Xi \times \mathrm{id}_{[0,1]}))_t \text{ as maps } \mathbb{R} \to \mathbb{R}^2 & \\ F_t'(\Xi(s)) & \overset{\downarrow}{=} & \mathrm{D}(F_t \circ \Xi)_s \cdot 1 & \overset{\downarrow}{=} \mathrm{D}((F \circ (\Xi \times \mathrm{id}_{[0,1]}))_t)_s \cdot 1 \\ & & & = \text{ vector in } \mathbb{R}^2 \text{ given by the two partial derivatives of} \\ & & & \uparrow \quad F \circ (\Xi \times \mathrm{id}_{[0,1]}) \text{ at } (s,t) \text{ in the first coordinate.} \\ & & & \text{by definition of the differential} \end{array}$$

Since $F\colon S^1 \times [0,1] \to S^1$ is smooth and since $\Xi \times \mathrm{id}_{[0,1]}\colon \mathbb{R} \times [0,1] \to S^1 \times [0,1]$ are smooth we know that $F \circ (\Xi \times \mathrm{id}_{[0,1]})\colon \mathbb{R} \times [0,1] \to \mathbb{R}^2$ is smooth. This implies, by the definition on page 531, that the partial derivatives are smooth. By the above calculation this shows that $(s,t) \mapsto F_t'(\Xi(s))$ is smooth. ■

Remark. Note that in the proof of Proposition 41.6 we made very much use of the fact a regular homotopy $F\colon S^1 \times [0,1] \to \mathbb{R}^2$ is by definition a smooth map. In the figure below we show a continuous map $F\colon S^1 \times [0,1] \to \mathbb{R}^2$ with $F_0 = \mu$ and $F_1 = \nu$, such that each $F_t\colon S^1 \to \mathbb{R}^2$ is an immersion. This shows that we cannot easily replace the condition that the map $F\colon S^1 \times [0,1] \to \mathbb{R}^2$ is smooth by a weaker condition.

There is nothing a topologist likes better than a complete characterization of a property. In this setting we are in this lucky situation, since the following theorem says that the converse to Proposition 41.6 also holds.

Theorem 41.7. (Whitney-Graustein Theorem) Two immersions $S^1 \to \mathbb{R}^2$ are regularly homotopic if and only if their rotation numbers agree.

Proof. The "only if"-statement is of course Proposition 41.6. The "if"-statement was first proved by Hassler Whitney [**Why1937**, p. 279] in 1937.[404] We will give the "standard proof" for the Whitney-Graustein Theorem 41.7, which relies on Proposition 41.3, whose proof we still owe to the reader. Thus the plan is as follows:

(1) In Section 41.2 we provide the overdue proof of Proposition 41.3.
(2) In Section 41.3 we will then give the "standard proof" for the Whitney-Graustein Theorem 41.7.

Note that there are several other proofs in the literature, see for example [**Gei2008**, Theorem 6.3.11], [**Gei2009**] and [**Pra2006**, p. 68], finally see also see the discussion in [**Kau1987**, p. 172]. ■

[404] Whitney [**Why1937**, p. 279] writes "this theorem, together with a straightforward proof, was suggested to me by W. C. Graustein".

41.2. **Proof of Proposition 41.3.** In this section we will finally prove Proposition 41.3, i.e. we will show that any immersion is regularly homotopic to an immersion of unit speed. Before we get into the nitty-gritty of the proof let us start out with a little preparation.

Definition. Given a smooth map $\mu\colon S^1 \to \mathbb{R}^n$ we define its length as

$$\text{length of } \mu \;:=\; \int_{r=0}^{r=2\pi} \|(\mu \circ \Xi)'(r)\|\, dr.$$

Lemma 41.8. Every immersion $\mu\colon S^1 \to \mathbb{R}^n$ is regularly homotopic to an immersion of length 2π.

Proof. Let $\mu\colon S^1 \to \mathbb{R}^n$ be an immersion. We denote its length by L. By Lemma 41.2 (1c) we know that $(\mu \circ \Xi)'(r) = \mu'(\Xi(r))$. Since μ is an immersion we see that $L > 0$. One can easily verify that the map

$$\begin{array}{rcl} F\colon \mathbb{R} \times [0,1] & \to & \mathbb{R}^n \\ (s,t) & \mapsto & \dfrac{1}{(1-t) + \frac{L}{2\pi} \cdot t} \cdot \mu(s) \end{array}$$

is a regular homotopy from μ to an immersion of length 2π. ■

Now we are ready to provide the proof of Proposition 41.3.

Proof of Proposition 41.3. Let $\gamma\colon S^1 \to \mathbb{R}^n$ be an immersion. We need to show that γ is regularly homotopic to an immersion $\delta\colon S^1 \to \mathbb{R}^n$ of unit speed, i.e. such that $\|\delta'(z)\| = 1$ for all $z \in S^1$. It follows from Lemmas 41.1 and 41.8 that it suffices to consider the case that the length of γ is equal to 2π.

Claim 1. We set $\widetilde{\gamma} := \gamma \circ \Xi\colon \mathbb{R} \to \mathbb{R}^n$. The map

$$\begin{array}{rcl} \lambda\colon \mathbb{R} & \to & \mathbb{R} \\ s & \mapsto & \displaystyle\int_{r=0}^{r=s} \|\widetilde{\gamma}'(r)\|\, dr \end{array}$$

is a diffeomorphism.

Proof. Recall that it follows from Lemma 41.2 (1c) that $r \mapsto \|\widetilde{\gamma}'(r)\|$ is non-zero for every $r \in \mathbb{R}$. It follows from the Fundamental Theorem of Calculus that $\lambda'(s) = \|\gamma'(s)\| \neq 0$ for all $s \in \mathbb{R}$. Furthermore note that it follows from Lemma 41.2 (1a) that $r \mapsto \|\widetilde{\gamma}'(r)\|$ is 2π-periodic. It follows easily from these two observations that $\lambda\colon \mathbb{R} \to \mathbb{R}$ is a bijection. Since the derivative is non-zero everywhere it follows from the Inverse Function Theorem 19.12 that λ is indeed a diffeomorphism. ⊞

Recall that the assume that γ has length one. This means that $\lambda(2\pi) = 2\pi$. Next we consider the map

$$\begin{array}{rcl} \widetilde{\delta}\colon \mathbb{R} & \to & \mathbb{R}^n \\ s & \mapsto & \widetilde{\gamma}(\lambda^{-1}(s)). \end{array}$$

Claim 2.

(1) The map $\widetilde{\delta}$ is 2π-periodic.

(2) For every $s \in \mathbb{R}$ we have $\|\widetilde{\delta}'(s)\| = 1$.

Proof. First we prove that $\widetilde{\delta}$ is 2π-periodic. We start out this proof with a preliminary calculation. Let $x \in \mathbb{R}$. We pick $n \in \mathbb{Z}$ with $n \cdot 2\pi \in [x, x+2\pi]$. We calculate that

$$\begin{aligned}
\lambda(x+2\pi) &= \int_0^{x+2\pi} \|\widetilde{\gamma}'(r)\|\,dr = \int_0^{x} \|\widetilde{\gamma}'(r)\|\,dr + \int_x^{x+2\pi} \|\widetilde{\gamma}'(r)\|\,dr \\
&= \int_0^{x} \|\widetilde{\gamma}'(r)\|\,dr + \int_x^{n\cdot 2\pi} \|\widetilde{\gamma}'(r)\|\,dr + \int_{n\cdot 2\pi}^{x+2\pi} \|\widetilde{\gamma}'(r)\|\,dr \\
&= \int_0^{x} \|\widetilde{\gamma}'(r)\|\,dr + \underbrace{\int_{x-(n-1)\cdot 2\pi}^{2\pi} \|\widetilde{\gamma}'(r)\|\,dr + \int_0^{x-(n-1)\cdot 2\pi} \|\widetilde{\gamma}'(r)\|\,dr}_{=\lambda(2\pi)=2\pi} = \lambda(x) + 2\pi.
\end{aligned}$$

(The middle equality is since $\widetilde{\gamma}'$ is 2π-periodic.)

In other words, we have shown that $x + 2\pi = \lambda^{-1}(\lambda(x) + 2\pi)$. It follows that for any $s \in \mathbb{R}$ we have

$$\widetilde{\delta}(s+2\pi) = \widetilde{\gamma}(\lambda^{-1}(s+2\pi)) \underset{\text{by the above applied to } x=\lambda^{-1}(s)}{=} \widetilde{\gamma}(\lambda^{-1}(s)+2\pi) \underset{\text{since } \widetilde{\gamma} \text{ is } 2\pi\text{-periodic}}{=} \widetilde{\gamma}(\lambda^{-1}(s)) = \widetilde{\delta}(s).$$

Thus we have shown that $\widetilde{\delta}$ is indeed 2π-periodic.

Now we turn to the proof that for every $s \in \mathbb{R}$ we have $\|\widetilde{\delta}'(s)\| = 1$. This is achieved by the following calculation:

$$\begin{aligned}
\|\widetilde{\delta}'(s)\| &\overset{\text{by definition of } \widetilde{\delta}}{=} \|(\widetilde{\gamma} \circ \lambda^{-1})'(s)\| \overset{\text{Chain Rule 19.10}}{=} \|\widetilde{\gamma}'(\lambda^{-1}(s)) \cdot (\lambda^{-1})'(s)\| \\
&\overset{\text{Smooth Invariance of Domain Proposition 19.11 (1)}}{=} \left\| \widetilde{\gamma}'(\lambda^{-1}(s)) \cdot \frac{1}{(\lambda')(\lambda^{-1}(s))} \right\| \\
&\underset{\text{Fundamental Theorem of Calculus}}{=} \left\| \widetilde{\gamma}'(\lambda^{-1}(s)) \cdot \frac{1}{\|\widetilde{\gamma}'(\lambda^{-1}(s))\|} \right\| = 1.
\end{aligned}$$

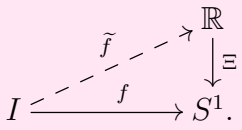
⊞

Claim 3. We consider the homotopy

$$\begin{aligned}
\widetilde{F} \colon \mathbb{R} \times [0,1] &\to \mathbb{R}^n \\
(s,t) &\mapsto \widetilde{\gamma}(s \cdot (1-t) + \lambda^{-1}(s) \cdot t)
\end{aligned}$$

from $\widetilde{\gamma}$ to $\widetilde{\delta}$. This homotopy has the property that each $\widetilde{F}_t$ is 2π-periodic and that each $\widetilde{F}_t$ is an immersion.

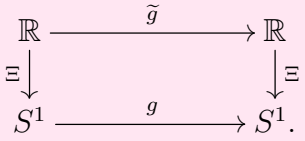
Proof. Let $t \in [0,1]$. It follows easily from Claim 2 (1) that $\widetilde{F}_t$ is indeed 2π-periodic. Furthermore note that for each $s \in \mathbb{R}$ we have



$$\widetilde{F}_t'(s) \underset{\text{chain rule}}{=} \overbrace{\widetilde{\gamma}'(s \cdot (1-t) + \lambda^{-1}(s) \cdot t)}^{\neq 0} \cdot \overbrace{(1 - t + \underbrace{(\lambda^{-1})'(s)}_{=\|\widetilde{\gamma}'(s)\| \text{ by FTC}} \cdot t)}^{>0} \neq 0.$$

⊞

Since $\widetilde{F}$ is evidently smooth and since by Claim 3 we know that each $\widetilde{F}_t$ is 2π-periodic it follows from Lemma 41.2 (2b) that there exists a smooth homotopy $F \colon S^1 \times [0,1] \to \mathbb{R}^n$ such that $F \circ (\Xi \times \mathrm{id}_{[0,1]}) = \widetilde{F}$. By design we have $F_0 = \gamma$. Note that it follows from Claim 2 (2) and Lemma 41.2 (1c) that F_1 has unit speed. Furthermore it follows from Claim 3 and Lemma 41.2 (1d) that each F_t is an immersion. In summary $F \colon S^1 \times [0,1] \to S^1$ is the desired regular homotopy. ■



41.3. **Proof of the "if"-statement of the Whitney-Graustein Theorem 41.7.** For the reader's convenience we recall two earlier statements.

Lemma 34.9. Let $I \subset \mathbb{R}$ be an interval and let $x_0 \in I$. Given any map $f\colon I \to S^1$ and given any $\widetilde{y}_0 \in \mathbb{R}$ with $f(x_0) = \widetilde{y}_0$ there exists a unique map $\widetilde{f}\colon I \to \mathbb{R}$ with $\widetilde{f}(x_0) = \widetilde{y}_0$ and such that $f = \Xi \circ \widetilde{f}$, i.e. such that the following diagram commutes;

We refer to $\widetilde{f}$ as a *lift* of f.

Lemma 41.9. Let $g\colon S^1 \to S^1$ be a smooth map and let $\widetilde{g}\colon \mathbb{R} \to \mathbb{R}$ be a map such that $\Xi \circ \widetilde{g} = g \circ \Xi$, i.e. such that the following diagram commutes:

Then for any $s \in \mathbb{R}$ we have

$$\deg(g\colon S^1 \to S^1) \;=\; \tfrac{1}{2\pi} \cdot \big(\widetilde{g}(s + 2\pi) - \widetilde{g}(s)\big).$$

Proof. This lemma follows basically immediately from the Degree-via-Lifts Lemma 38.10 applied to the map $f\colon [0,1] \to \mathbb{R}$ that is given by $f(t) = g(s + 2\pi \cdot t)$. ■

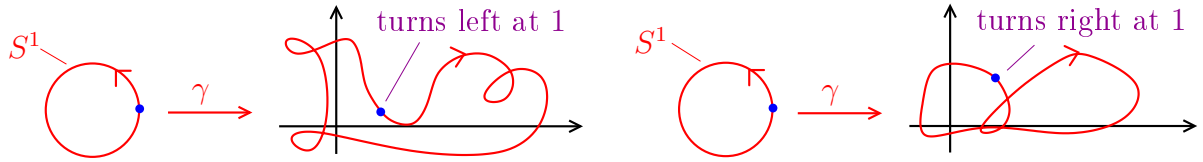
We will also need the following lemma.

Lemma 41.10. If $\Theta\colon [0,1] \to S^n$ is a non-constant map, then

$$\left\| \int_{r=0}^{r=1} \Theta(r)\, dr \right\| \;<\; \int_{r=0}^{r=1} \|\Theta(r)\|\, dr.$$

Proof. We view Θ as a map $[0,1] \to \mathbb{R}^{n+1}$. the Integral Inequality Lemma 0.16 says that the following inequality holds:

$$\left\| \int_{r=0}^{r=1} \Theta(r)\, dr \right\| \;\leq\; \int_{r=0}^{r=1} \|\Theta(r)\|\, dr \qquad \in \mathbb{R}.$$



Furthermore the Integral Inequality Lemma 0.16 says that equality holds if and only if there exists a $w \in \mathbb{R}^{n+1}$ and a map $\lambda\colon [a,b] \to \mathbb{R}_{\geq 0}$ such that for every $t \in [a,b]$ we have $\Theta(t) = \lambda(t) \cdot w$. Since Θ takes values in S^n we see that equality only holds if Θ is a constant map. ■

In the remainder of this section we will need the following geometric definition.

Definition. Let $\gamma\colon S^1 \to \mathbb{R}^2 = \mathbb{C}$ be an immersion of unit speed, i.e. such that $\gamma'(z) \in S^1$ for all $z \in S^1$. By the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 there exists a smooth map $\Lambda_\gamma\colon \mathbb{R} \to \mathbb{R}$ such that for all $s \in \mathbb{R}$ we have $\Xi(\Lambda_\gamma(s)) = (\gamma \circ \Xi)'(s) \in S^1$.

(1) We say $\gamma\colon S^1 \to \mathbb{R}^2$ turns left at $1 \in S^1$ if $\Lambda'_\gamma(0) > 0$.[405]

(2) We say $\gamma\colon S^1 \to \mathbb{R}^2$ turns right at $1 \in S^1$ if $\Lambda'_\gamma(0) > 0$.

Lemma 41.11. Let $\gamma\colon S^1 \to \mathbb{R}^2$ be an immersion of unit speed.

(1) If the rotation number $\rho(\gamma) \geq 0$, then γ is regularly homotopic to an immersion of unit speed that turns left at $1 \in S^1$.
(2) If the rotation number $\rho(\gamma) \leq 0$, then γ is regularly homotopic to an immersion of unit speed that turns right at $1 \in S^1$.

Proof. Let $\gamma\colon S^1 \to \mathbb{R}^2$ be an immersion of unit speed. Evidently we only deal with one of the two cases of the lemma. For no particular reason we deal with the case that $\rho(\gamma) \geq 0$. Recall that by the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 there exists a map $\Lambda\colon \mathbb{R} \to \mathbb{R}$ such that for all $s \in \mathbb{R}$ we have $\Xi(\Lambda(s)) = (\gamma \circ \Xi)'(s)$.

Claim. There exists a $w \in \mathbb{R}$ with $\Lambda'(w) > 0$.

Proof. Note that

$$\text{(A)} \qquad \int_{t=0}^{t=2\pi} \Lambda'(t)\,dt \underset{\text{Fundamental Theorem of Calculus}}{=} \Lambda(2\pi) - \Lambda(0) \underset{\text{by Lemma 41.9}}{=} \deg(\gamma') \underset{\text{by definition of } \rho(\gamma)}{=} \rho(\gamma).$$

If $\rho(\gamma) > 0$ then it is clear from this calculation that there exists a $w \in [0, 2\pi]$ with $\Lambda'(w) > 0$. It remains to consider the case $\rho(\gamma) = 0$. Note that we have

$$\text{(B)} \qquad 0 \underset{\text{since } \gamma\circ\Xi \text{ is } 2\pi\text{-periodic}}{=} (\gamma \circ \Xi)(2\pi) - (\gamma \circ \Xi)(0) \underset{\text{Fundamental Theorem of Calculus}}{=} \int_{t=0}^{t=2\pi} \overbrace{(\gamma \circ \Xi)'(t)}^{\in S^1}\,dt.$$

Since γ has unit speed we know that each $(\gamma \circ \Xi)'(t) \in S^1$. Thus the integral in (B) can only be zero if $(\gamma \circ \Xi)'(t)$ is not constant. This implies that Λ is not constant. But this implies that Λ' cannot be identically zero. But the only way how the integral in (A) can be zero is now that Λ' assumes negative and positive values. ⊞

We have now shown that γ turns left at some point in S^1. It remains to shift this point to $1 \in S^1$. To do so we consider the following map

$$\begin{aligned} F\colon S^1 \times [0,1] &\to \mathbb{R}^2 \\ (z,t) &\mapsto \gamma(z \cdot \exp(\mathrm{i} \cdot w \cdot t)). \end{aligned}$$

One can easily verify that this map is smooth and that each F_t is an immersion of unit speed. In particular F is a regular homotopy from $F_0 = \gamma$ to $F_1 =: \delta$. Finally note that by construction we see that δ turns left at 0. ■

[405] The map Λ_γ is well-defined up to addition of a multiple of 2π. We see that the notion of turning left and right is independent of the choice of Λ_γ.

Now we can finally provide the proof of the "if"-statement of the Whitney-Graustein Theorem 41.7.

Proof of the "if"-statement of the Whitney-Graustein Theorem 41.7. In the following let $\alpha, \beta\colon S^1 \to \mathbb{R}^2$ be two immersions with $\rho(\alpha) = \rho(\beta)$. We need to show that α and β are regularly homotopic. In the following we will deal with the case that $\rho(\alpha) = \rho(\beta) \geq 0$. The case that $\rho(\alpha) = \rho(\beta) < 0$ is proved by an almost identical argument, namely, in the discussion below we just need to replace Lemma 41.11 (1) by Lemma 41.11 (2).

We start out with a few initial observations. In Lemma 41.1 we showed that being regularly homotopic is an equivalence relation. It follows from this observation, together with Proposition 41.3, Lemma 41.11 (1) and Proposition 41.6 that we can assume that the two given immersions $\alpha, \beta\colon S^1 \to \mathbb{R}^2$ have the following properties:

(I) Both α and β are of unit speed.
(II) Both α and β turn left at $1 \in S^1$.

Furthermore, after a translation we can as well assume that the following condition is satisfied:

(III) We have $\alpha(1) = \beta(1) = 0 \in \mathbb{C}$.

Since $\alpha, \beta\colon S^1 \to \mathbb{R}^2 = \mathbb{C}$ are immersions of unit speed we get maps $\alpha', \beta'\colon S^1 \to S^1$. Thus we obtain once again from the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 that there exist smooth maps $\Lambda_{\alpha'}, \Lambda_{\beta'}\colon \mathbb{R} \to \mathbb{R}$ such that $\Xi \circ \widetilde{\alpha'} = \alpha' \circ \Xi$ and such that $\Xi \circ \Lambda_{\beta'} = \beta' \circ \Xi$.

For orientation we summarize the various maps in the following commutative diagram:

$$\begin{array}{ccc} \mathbb{R} & \xrightarrow{\Lambda_{\alpha'}} & \mathbb{R} \\ {\scriptstyle s \mapsto \exp(\mathrm{i}s)}\downarrow{\scriptstyle \Xi} & & {\scriptstyle \Xi}\downarrow{\scriptstyle s \mapsto \exp(\mathrm{i}s)} \\ S^1 & \xrightarrow[z \mapsto \alpha'(z)]{} & S^1. \end{array}$$

On page 952 we saw that the standard homotopy $(z,t) \mapsto \alpha(z)\cdot(1-t)+\beta(z)\cdot t$ shows that α and β are homotopic. In general this homotopy is not a regular homotopy. To obtain a regular homotopy, under the hypothesis that $\rho(\alpha) = \rho(\beta)$ we will use a variation on the standard homotopy. More precisely, the idea is now as follows:

(a) we consider the lifts $\widetilde{\alpha'}$ and $\Lambda_{\beta'}$ of the *derivatives* of $\Xi \circ \alpha$ and $\Xi \circ \beta$,
(b) we consider the standard homotopy of $\widetilde{\alpha'}$ and $\Lambda_{\beta'}$,
(c) we apply Ξ to the homotopy from (b) and we integrate, to "undo" taking the derivative,
(d) we obtain a regular homotopy $\widetilde{F}\colon \mathbb{R} \times [0,1] \to \mathbb{R}^n$ between $\alpha \circ \Xi$ and $\beta \circ \Xi$,
(e) finally, and that is the most delicate step, we need to modify $\widetilde{F}$ to obtain a regular homotopy $\widetilde{G}$ that descends to a regular homotopy on S^1.

Next we consider the homotopy

$$\begin{array}{rcl} \Theta\colon \mathbb{R} \times [0,1] & \to & S^1 \\ (s,t) & \mapsto & \Xi\big(\Lambda_{\alpha'}(s)\cdot(1-t) + \Lambda_{\beta'}(s)\cdot t\big). \end{array}$$

Claim 1.

(1) Each Θ_t is 2π-periodic.
(2) Each $\Theta_t\colon \mathbb{R} \to \mathbb{R}$ is non-constant.

Proof. Let $t \in [0,1]$.

(1) Let $s \in \mathbb{R}$. We need to show that $\Theta_t(s+2\pi) = \Theta_t(s)$. The statement follows immediately from the fact that Ξ is 2π-periodic and the following calculation:

$$\begin{array}{rcl} \Lambda_{\alpha'}(s+2\pi)\cdot(1-t)+\Lambda_{\beta'}(s+2\pi)\cdot t & \overset{\text{by Lemma 41.9 we have } \Lambda_{\alpha'}(s+2\pi)-\Lambda_{\alpha'}(s)=2\pi\cdot\deg(\alpha')=2\pi\cdot\rho(\alpha) \text{ and we have } \Lambda_{\beta'}(s+2\pi)-\Lambda_{\beta'}(s)=2\pi\cdot\deg(\beta')=2\pi\cdot\rho(\beta)}{=} & (\Lambda_{\alpha'}(s)+2\pi\cdot\rho(\alpha))\cdot(1-t)+(\Lambda_{\beta'}(s)+2\pi\cdot\rho(\beta))\cdot t \\ & = & \Lambda_{\alpha'}(s)\cdot(1-t)+\Lambda_{\beta'}(s)\cdot t+\underbrace{2\pi\cdot\rho(\alpha)}_{\in 2\pi\cdot\mathbb{Z}}. \\ & \overset{\text{follows from the hypothesis that } \rho(\alpha)=\rho(\beta)}{=} & \end{array}$$

(2) Let $t \in [0,1]$. Note that by (II) we know that $\Lambda_{\alpha'}(0) > 0$ and that $\Lambda'_{\beta'}(0) > 0$. It follows that the derivative of $s \mapsto \widetilde{\alpha'}(s)\cdot(1-t)+\Lambda_{\beta'}(s)\cdot t$ is positive at $s=0$. It follows that Θ_t is non-constant. ⊞

We use this homotopy $\Theta\colon \mathbb{R}\times[0,1]\to S^1$ to define the following map:

$$\begin{array}{rcl} \widetilde{F}\colon \mathbb{R}\times[0,1] & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & \int\limits_{r=0}^{r=s} \Theta_t(r)\,dr. \end{array}$$

Claim 2. The map $\widetilde{F}$ has the following properties:
(1) $\widetilde{F}$ is smooth.
(2) $\widetilde{F}_0 = \alpha\circ\Xi$ and $\widetilde{F}_1 = \beta\circ\Xi$.

Proof.

(1) Note that α and β are smooth. As we mentioned in Lemma 34.8, it follows from the fact that $q\colon\mathbb{R}\to S^1$ is a local diffeomorphism that $\Lambda_{\alpha'}$ and $\Lambda_{\beta'}$ are smooth. It now follows from standard facts in real analysis, e.g. the Leibniz Integral Rule [**PedS2015**, Theorem 9.2.11], that $\widetilde{F}$ is smooth.
(2) Given any $s\in\mathbb{R}$ we perform the following calculation:

$$\begin{array}{rcccccl} \widetilde{F}(s,0) & = & \int\limits_{r=0}^{r=s}\Theta(r,0)\,dr & = & \int\limits_{r=0}^{r=s}(\Xi\circ\Lambda_{\alpha'})(r)\,dr & = & \int\limits_{r=0}^{r=s}(\alpha\circ\Xi)'(r)\,dr \quad = \quad (\alpha\circ\Xi)(s). \\ & \uparrow & & \uparrow & & \uparrow & \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\ & \text{by definition of } \widetilde{F} & & \text{by definition of } \Theta(r,0) & & \text{since we have } \Xi\circ\Lambda_{\alpha'}=\alpha'\circ\Xi=(\alpha\circ\Xi)' & \text{follows from the Fundamental Theorem of Calculus and fact that } (\alpha\circ\Xi)(0)=0 \end{array}$$

The same argument shows that $\widetilde{F}_1 = \beta\circ\Xi$. ⊞

All this sounds very promising. But unfortunately there is a problem with the homotopy $\widetilde{F}\colon\mathbb{R}\times[0,1]\to\mathbb{R}^2$: there is no reason why the maps $\widetilde{F}_t$ should be 2π-periodic, i.e. why

they should descend to a map $S^1 \to \mathbb{R}^2$. To fix this issue we consider the following map:[406]

$$\begin{array}{rccl} \widetilde{G}\colon \mathbb{R}\times[0,1] & \to & \mathbb{R}^2 & \\ (s,t) & \mapsto & \widetilde{F}(s,t) - \frac{s}{2\pi}\cdot\widetilde{F}(2\pi,t) & = \int\limits_{r=0}^{r=s} \Theta_t(r)\,dr \;-\; \frac{s}{2\pi}\cdot\int\limits_{r=0}^{r=2\pi}\Theta_t(r)\,dr. \end{array}$$

Claim 3. The map $\widetilde{G}$ has the following properties:
(1) Each $\widetilde{G}_t$ is 2π-periodic.
(2) $\widetilde{G}$ is smooth.
(3) $\widetilde{G}_0 = \alpha\circ\Xi$ and $\widetilde{G}_1 = \beta\circ\Xi$.
(4) For each $t\in[0,1]$ the map $\widetilde{G}_t\colon\mathbb{R}\to\mathbb{R}^2$ is an immersion.

Proof.

(1) Let $t\in[0,1]$. We need to show that for each $s\in\mathbb{R}$ we have $\widetilde{G}(s+2\pi,t) = \widetilde{G}(s,t)$. Evidently it suffices to show that for every $s\in[0,2\pi)$ and every $n\in\mathbb{Z}$ we have $\widetilde{G}(s+2\pi\cdot n,t) = \widetilde{G}(s,t)$. We perform the following elementary calculation:

$$\begin{aligned} \widetilde{G}(s+2\pi n,t) &= \int_0^{2\pi n+s}\Theta_t(r)\,dr \;-\; \tfrac{2\pi n+s}{2\pi}\cdot\int_0^{2\pi}\Theta_t(r)\,dr \;= \\ &\quad \text{(by definition and by the additivity of the integral)} \\ &= \sum_{k=0}^{n-1}\int_{2\pi k}^{2\pi(k+1)}\Theta_t(r)\,dr \;-\; n\cdot\int_0^{2\pi}\Theta_t(r)\,dr + \int_{2\pi n}^{2\pi n+s}\Theta_t(r)\,dr - \tfrac{s}{2\pi}\cdot\int_0^{2\pi}\Theta_t(r)\,dr \\ &= \underbrace{\sum_{k=0}^{n-1}\int_0^{2\pi}\Theta_t(r)\,dr \;-\; n\cdot\int_0^{2\pi}\Theta_t(r)\,dr}_{=0} + \underbrace{\int_0^{s}\Theta_t(r)\,dr - \tfrac{s}{2\pi}\cdot\int_0^{2\pi}\Theta_t(r)\,dr}_{=\widetilde{G}(s,t)} \;=\; \widetilde{G}(s,t) \end{aligned}$$

(since by Claim 1 (1) we know that Θ_t is 2π-periodic)

(2) It follows easily from Claim 2 (1) that $\widetilde{G}$ is smooth.
(3) Let $s\in\mathbb{R}$. We see that

$$\begin{aligned} \widetilde{G}_0(s) &\overset{\text{by definition}}{=} \widetilde{F}_0(s) - \tfrac{s}{2\pi}\cdot\widetilde{F}_0(2\pi) \overset{\text{by Claim 2 (2)}}{=} (\alpha\circ\Xi)(s) - \tfrac{s}{2\pi}\cdot(\alpha\circ\Xi)(2\pi) \\ &= (\alpha\circ\Xi)(s) - \tfrac{s}{2\pi}\cdot\underbrace{(\alpha\circ\Xi)(0)}_{=0 \text{ by (III)}} \;=\; (\alpha\circ\Xi)(s). \end{aligned}$$

(since $\alpha\circ\Xi$ is 2π-periodic)

The same argument shows that $\widetilde{G}_1 = \beta\circ\Xi$.

[406] While writing this chapter the author regretted on numerous occasions the fact that 1 is not equal to 2π.

(4) Let $t \in [0,1]$. We need to show that for every $s \in \mathbb{R}$ we have $\widetilde{G}_t{}'(s) \neq 0$. Thus let $s \in \mathbb{R}$. Note that

$$\|\widetilde{G}_t{}'(s)\| \;=\; \left\| \Theta_t(s) - \frac{1}{2\pi} \int_{r=0}^{r=2\pi} \Theta_t(r)\, dr \right\| \;\geq\; \|\Theta_t(s)\| - \frac{1}{2\pi} \cdot \left\| \int_{r=0}^{r=2\pi} \Theta_t(r)\, dr \right\|$$

$=$: by the Fundamental Theorem of Calculus applied to the first term of $\widetilde{G}_t(s)$ and by linearity of the second term of $\widetilde{G}_t(s)$

$\geq$: triangle inequality

$$> \; \underbrace{\|\Theta_t(s)\|}_{=1} - \frac{1}{2\pi} \cdot \int_{r=0}^{r=2\pi} \underbrace{\|\Theta_t(r)\|}_{=1}\, dr \; > \; 0.$$

$>$: follows from Lemma 41.10, since we know by Claim 1 (2) that the map Θ_t is not constant ⊞

It follows from Claim 3 (1) and (3) together with Lemma 41.2 (2b) that there exists a smooth map

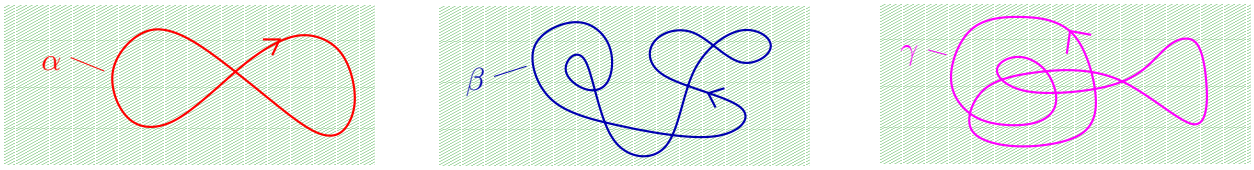
$$G\colon S^1 \times [0,1] \;\to\; \mathbb{R}^2$$

such that for all $(s,t) \in \mathbb{R} \times [0,1]$ we have $G(\Xi(s),t)) = \widetilde{G}(s,t)$. It follows easily from the above properties of $\widetilde{G}$ that G is the desired regular homotopy between α and β. ■

Exercises for Chapter 41.

Exercise 41.1. Let $n \geq 3$. Show that any two immersions $S^1 \to \mathbb{R}^n$ are regularly homotopic.
Hint. Use Propositions 30.2 and 30.3.

Exercise 41.2. Let $n \in \mathbb{Z} \setminus \{0\}$. Use Lemma 41.9 to give a new proof of Lemma 41.5, i.e. show that



$$\rho \begin{pmatrix} S^1 & \to & \mathbb{C} \\ z & \mapsto & z^n \end{pmatrix} \;=\; n.$$

Exercise 41.3. Let $\mu\colon S^1 \to \mathbb{R}^n$ be a smooth map. As on page 958 we define its length as

$$\text{length of } \mu \;:=\; \int_{r=0}^{r=2\pi} \|(\mu \circ \Xi)'(r)\|\, dr.$$

(Here we use the notation from page 953.) Show that if $\Phi\colon S^1 \to S^1$ is a diffeomorphism, then the lengths of μ and $\mu \circ \Phi$ agree.

Exercise 41.4. Determine the rotation numbers of the immersions indicated in the figure below.

Exercise 41.5. Let $\alpha, \beta\colon S^1 \to \mathbb{R}^2$ be immersions. We suppose that there exists a continuous map $F\colon S^1 \times [0,1] \to \mathbb{R}^2$ with the following properties:

(1) Each F_t is an immersion.
(2) $F_0 = \alpha$ and $F_1 = \beta$.

(3) For each $z \in S^1$ the map $[0,1] \to \mathbb{R}^2$ given by $t \mapsto F'_t(z)$ is continuous.

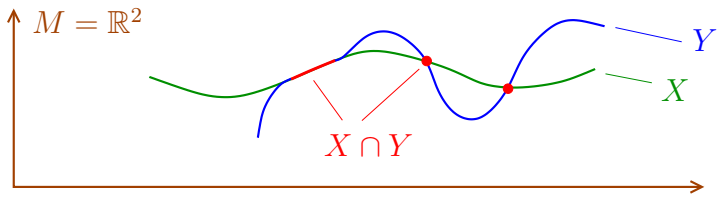
Does this imply that the rotation numbers of α and β agree?

42. The transversality theorem

In this chapter we will do the following:

(1) We will define what it means for two submanifolds of a given smooth manifold to be transverse.
(2) We will see that if two submanifolds are transverse, then the intersection is again a submanifold.
(3) We will see that given two submanifolds we can always perform an isotopy of one of the two submanifolds to obtain a transverse intersection.

Throughout this chapter we will work with two already familiar conventions which will make our life much easier. First we recall the following convention from page 633



Convention. Let M be a smooth manifold.

(1) Given $P \in \partial M$ we view $\mathrm{T}_P \partial M$ as a vector subspace of $\mathrm{T}_P M$.
(2) Given a submanifold W and given $P \in W$ we view $\mathrm{T}_P W$ as a vector subspace of $\mathrm{T}_P M$.

Secondly we adopt the following convention.

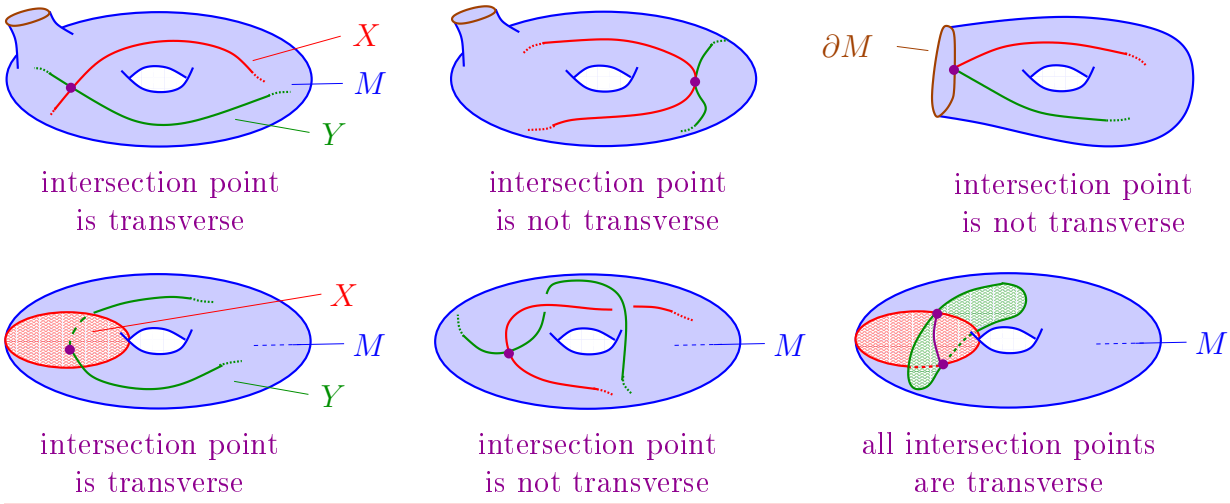
Convention. Given a smooth submanifold M of some $\mathbb{R}^n$ and given $P \in M$ we use the natural isomorphism from the Tangent Space-Isomorphism Proposition 23.16 as an excuse for not distinguishing in our notation between the abstract tangent space $\mathrm{T}_P M$ and the physical tangent space $\widetilde{\mathrm{T}}_P M$. We will always just write $\mathrm{T}_P M$.

42.1. **The Transversal Intersection Theorem.** In this section we want to study the following question: given a smooth manifold M and two submanifolds X and Y, is the intersection $X \cap Y$ again a submanifold of M? It is not difficult to show that in general the answer is negative. For example consider $M = \mathbb{R}^2$ with the two submanifolds X and Y that are shown in the below. The intersection $X \cap Y$ has three components, one of which is a submanifold of dimension one, and the other two components consist of a single point. We see that $X \cap Y$ is not a smooth manifold (after all, what would its dimension be?), in particular it is not a submanifold of M.

If one spends some time pondering the question why in the previous example the intersection $X \cap Y$ is not a submanifold, then one is inexorably led towards the following definition.

Definition. Let M be a smooth manifold. Let X and Y be proper submanifolds of M.

(1) Let $P \in X \cap Y$. We say P is a transverse intersection point if X and Y intersect transversally in P, i.e. if the equality[407]



$$\mathrm{T}_P X + \mathrm{T}_P Y \;=\; \mathrm{T}_P M$$

holds. If $P \in \partial M$, then we also demand that[408]

$$\mathrm{T}_P(X \cap \partial M) + \mathrm{T}_P(Y \cap \partial M) \;=\; \mathrm{T}_P\,\partial M.$$

(2) We say that X and Y intersect transversally if each intersection point is a transverse intersection point.

(3) We abbreviate the expression "X and Y intersect transversally" by $X \pitchfork Y$.

intersection point is transverse | intersection point is not transverse | intersection point is not transverse

intersection point is transverse | intersection point is not transverse | all intersection points are transverse

Theorem 42.1. (Submanifold Transversal Intersection Theorem) Let M be an m-dimensional smooth manifold, let $X \subset M$ be a proper submanifold of codimension k and let Y be a proper submanifold of M of codimension l.

(1) Let $P \in M$ be a transverse intersection point of X and Y.

(a) If $P \notin \partial M$, then there exists a chart $\Phi\colon U \to V$ of type (i) around P with

$$\Phi(U \cap X) = V \cap (\mathbb{R}^{m-k} \times \{0\}) \quad \& \quad \Phi(U \cap Y) = V \cap (\{0\} \times \mathbb{R}^{m-l}).$$

(b) If $P \in \partial M$, then there exists a chart $\Phi\colon U \to V$ of type (ii) around P with

$$\Phi(U \cap X) = V \cap (\mathbb{R}^{m-k-1} \times \{0\} \times \mathbb{R}_{\geq 0}) \quad \& \quad \Phi(U \cap Y) = V \cap (\{0\} \times \mathbb{R}^{m-l-1} \times \mathbb{R}_{\geq 0}).$$

(2) If the submanifolds X and Y intersect transversally, i.e. if $X \pitchfork Y$, then the following statements hold:

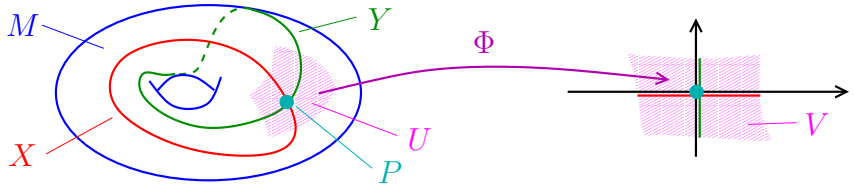
(a) The intersection $X \cap Y$ is a proper submanifold of M of codimension $k + l$. Furthermore $X \cap Y$ is proper submanifold of X and of Y.

(b) For every $P \in X \cap Y$ we have

$$\mathrm{T}_P(X \cap Y) \;=\; \mathrm{T}_P X \cap \mathrm{T}_P Y \;\subset\; \mathrm{T}_P M.$$

(c) Let M, X and Y be oriented.

(i) By hypothesis for each $P \in X \cap Y$ the vector spaces $\mathrm{T}_P M$, $\mathrm{T}_P X$ and $\mathrm{T}_P Y$ are oriented. By (2b) we can equip $\mathrm{T}_P(X \cap Y) = \mathrm{T}_P X \cap \mathrm{T}_P Y$ with the

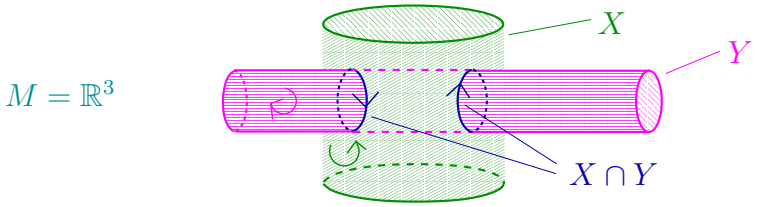


[407] Since X is a submanifold of M we can use the above convention to view the tangent space $\mathrm{T}_P X$ as a vector subspace of $\mathrm{T}_P M$.

[408] Note that in Exercise 19.31 (a) we showed that $X \cap \partial M$ and $Y \cap \partial M$ are submanifolds of ∂M, thus it makes sense to consider their tangent spaces.

intersection orientation that we introduced on page 673. These orientations define an orientation on $X \cap Y$.

(ii) The orientations on the smooth manifolds $\partial X \cap \partial Y$ and $\partial(X \cap Y)$ agree.[409]



(d) If one of X or Y is compact, then so is $X \cap Y$.

Remark. In the next section we will prove the Transversal Preimage Theorem 42.3 which is a generalization of the Submanifold Transversal Intersection Theorem 42.1 (2).

Definition. Let M be a smooth manifold and let X and Y be proper oriented submanifolds of M that intersect transversally. We refer to the orientation on $X \cap Y$ that we introduced in the Submanifold Transversal Intersection Theorem 42.1 (2) as the intersection orientation.

Example. In the figure below we see two oriented infinite cylinders X and Y in the oriented smooth manifold $\mathbb{R}^3$. The cylinders are submanifolds of codimension one. They intersect transversally and the intersection consists of two circles, i.e. $X \cap Y$ is a one-dimensional submanifold of $\mathbb{R}^3$. Put differently, $X \cap Y$ is a submanifold of codimension two.

Auxiliary Lemma 42.2. Let W be an m-dimensional real vector space, let U be an $(m-k)$-dimensional vector subspace of W and let V be an $(m-l)$-dimensional vector subspace of W. We assume that $U + V = W$. Furthermore let $\Theta\colon W \to \mathbb{R}^l \oplus \mathbb{R}^{m-k-l} \oplus \mathbb{R}^k$ be an isomorphism. If $\Theta(U) = \mathbb{R}^l \oplus \mathbb{R}^{m-k-l} \oplus \{0\}$ and if $\Theta(U \cap V) = \{0\} \oplus \mathbb{R}^{m-k-l} \oplus \{0\}$, then the map

$$V \xrightarrow{\Theta} \mathbb{R}^l \oplus \mathbb{R}^{m-k-l} \oplus \mathbb{R}^k \xrightarrow{\text{projection}} \mathbb{R}^{m-k-l} \oplus \mathbb{R}^k$$

is an isomorphism.

Proof of Lemma 42.2. For dimension reasons we only have to show that the given map $V \to \mathbb{R}^{m-k-l} \oplus \mathbb{R}^k$ is an epimorphism. Thus let $y \oplus z \in \mathbb{R}^{m-k-l} \oplus \mathbb{R}^k$. Since Θ is an isomorphism there exists a $w \in W$ with $\Theta(w) = 0 \oplus y \oplus z$. Since $U + V = W$ there exist $u \in U$ and $v \in V$ with $u + v = w$. By hypothesis $\Theta(u) = x' \oplus y' \oplus 0$ for some $x' \in \mathbb{R}^l$ and $y' \in \mathbb{R}^{m-k-l}$. Furthermore by hypothesis we have $\Theta(U \cap V) = \{0\} \oplus \mathbb{R}^{m-k-l} \oplus \{0\}$. From $U + V = W$ it follows from elementary linear algebra that $U \cap V$ is also of dimension

[409] Here we give $X \cap Y$ the orientation from (i) and we give $\partial(X \cap Y)$ the boundary orientation from page 689. Furthermore we equip ∂X, ∂Y and ∂M with the boundary orientations. By definition of transverse intersection we also have $\partial X \pitchfork \partial Y$. Thus we can use (i) to equip $\partial X \cap \partial Y$ with an orientation.

$m-k-l$. Thus the map $\Theta\colon U\cap V\to\{0\}\oplus\mathbb{R}^{m-k-l}\oplus\{0\}$ is actually an isomorphism. Thus there exists a $\widetilde{v}\in V$ with $\Theta(\widetilde{v})=0\oplus y'\oplus 0$. Now we see that

$$\Theta(v-\widetilde{v}) \;=\; \Theta(w)-\Theta(u)-\Theta(\widetilde{v}) = 0\oplus y\oplus z - x'\oplus y'\oplus 0 - 0\oplus y'\oplus 0 \;=\; (-x')\oplus y\oplus z.$$

Thus we have shown that $y\oplus z$ lies in the image of the given map $V\to\mathbb{R}^{m-k-l}\oplus\mathbb{R}^k$. ■

Proof of the Submanifold Transversal Intersection Theorem 42.1. Let M be an m-dimensional smooth manifold, let $X\subset M$ be a proper submanifold of codimension k and let Y be a proper submanifold of M of codimension l.

(1) Let $P\in M$ be a transverse intersection point of X and Y. In the following we will deal with the case that $P\notin\partial M$. The case $P\in\partial M$ is proved in a similar fashion, we leave it to the reader to fill in the details for the case $P\in\partial M$.

Since X is a proper submanifold of M and since $P\notin\partial M$ we can pick a submanifold chart $\Theta\colon A\to B$ of type (α) for X around P. We can arrange that $\Theta(P)=0$. Note that $\mathrm{D}\Theta_P(\mathrm{T}_PX)=\mathbb{R}^{m-k}\times\{0\}$. Since P is a transverse intersection point we see that $\mathrm{D}\Theta_P(\mathrm{T}_PX\cap\mathrm{T}_PY)$ is a vector subspace of $\mathbb{R}^{m-k}\times\{0\}\subset\mathbb{R}^m$ of dimension $m-k-l$. Elementary linear algebra shows that there exists an $A\in\mathrm{GL}(m,R)$ with $A\cdot(\mathbb{R}^{m-k}\times\{0\})=\mathbb{R}^{m-k}\times\{0\}$ and $A\cdot\mathrm{D}\Theta_P(\mathrm{T}_PX\cap\mathrm{T}_PY)=\{0\}\times\mathbb{R}^{m-k-l}\times\{0\}\subset\mathbb{R}^m$. After composing Θ with multiplication by the matrix A we might as well assume that $\mathrm{D}\Theta_P(\mathrm{T}_PX\cap\mathrm{T}_PY)=\{0\}\times\mathbb{R}^{m-k-l}\times\{0\}\subset\mathbb{R}^m$.

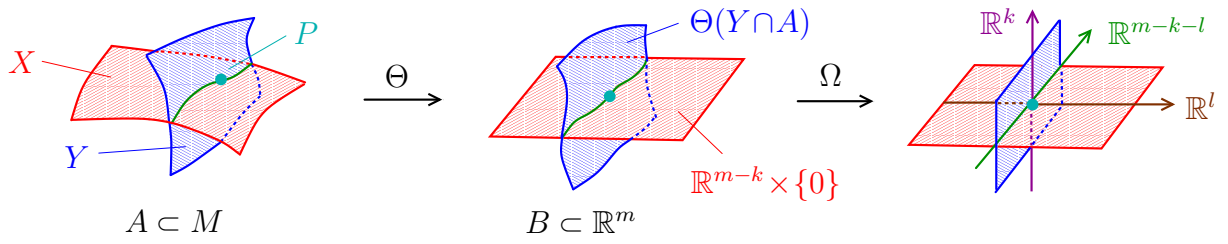
Next we consider the projections

$$\begin{array}{rcl} p_1\colon \mathbb{R}^m=\mathbb{R}^l\times\mathbb{R}^{m-l} & \to & \mathbb{R}^l \\ (x_1,x_2) & \mapsto & x_1 \end{array} \qquad\text{and}\qquad \begin{array}{rcl} p_2\colon \mathbb{R}^m=\mathbb{R}^l\times\mathbb{R}^{m-l} & \to & \mathbb{R}^{m-l} \\ (x_1,x_2) & \mapsto & x_2. \end{array}$$

Since P is a transverse intersection point we obtain from the elementary Lemma 42.2 that $p_2\colon \mathrm{T}_P(\Theta(Y\cap A))\to\mathbb{R}^{m-l}$ is an isomorphism. It follows from the Inverse Mapping Theorem 24.1 that $p_2\colon\Theta(Y\cap A)\to\mathbb{R}^{m-l}$ is a local diffeomorphism at 0. This implies that there exists an open neighborhood B_2 of $0\in\mathbb{R}^{m-l}$ such that the restriction of p_2 to $\Theta(Y\cap A)\cap(\mathbb{R}^l\times B_2)\to B_2$ is a diffeomorphism. We denote by q_2 the inverse. We pick an open subset $B_1\subset\mathbb{R}^l$ such that $B_1\times B_2\subset B$ and we consider the map

$$\begin{array}{rcl} \Omega\colon B_1\times B_2 & \to & \mathbb{R}^l\times\mathbb{R}^{m-l} \\ (x_1,x_2) & \mapsto & (x_1-(p_1\circ q_2)(x_2),x_2). \end{array}$$

Claim. The map



$$\Phi \;:=\; \Omega\circ\Theta\colon \Theta^{-1}(B_1\times B_2) \;\to\; \Omega(B_1\times B_2)$$

has all the desired properties.

Proof. One can easily verify that an inverse to Ψ is given by

$$\begin{array}{rcl} \Psi\colon \Omega(B_1\times B_2) & \to & \Theta^{-1}(B_1\times B_2) \\ (x_1,x_2) & \mapsto & \Theta^{-1}(x_1+(p_1\circ q_2)(x_2),x_2). \end{array}$$

This shows that Φ is a bijection. Furthermore one can easily verify that the differential of Φ at each point is invertible. Thus it follows from the Inverse Mapping Theorem 24.1 together with the Smooth Pasting Proposition 19.23 (2) that Φ is actually a diffeomorphism. This shows that Φ is a chart of type (i). Finally note that by construction we have $\Phi(U\cap X)=V\cap(\mathbb{R}^{m-k}\times\{0\})$ and $\Phi(U\cap Y)=V\cap(\{0\}\times\mathbb{R}^{m-l})$. ⊞

(2) (a) The charts constructed in (1) define, after possibly reordering the coordinates, submanifold charts of type (α) and (β) for $X \cap Y \subset M$. Since X and Y are closed the intersection $X \cap Y$ is also closed. This shows that $X \cap Y$ is a proper submanifold of codimension $k+l$ of M.
A slight modification of the above argument shows that $X \cap Y$ is also a proper submanifold of X and of Y.

(b) Let $P \in X \cap Y$. By (2a) we know that $X \cap Y$ is a proper submanifold of M of codimension $k+l$. Thus $\mathrm{T}_P(X \cap Y)$ is a vector space of dimension $m-k-l$. Since P is a transverse intersection we obtain from an elementary linear algebra argument that $\mathrm{T}_P X \cap \mathrm{T}_P Y$ is also of dimension $m-k-l$. As discussed in (2a), $X \cap Y$ is a proper submanifold of X and Y, thus $\mathrm{T}_P(X \cap Y) \subset \mathrm{T}_P X \cap \mathrm{T}_P Y$. Since the dimensions are equal we see that the vector spaces are the same.

(c) (i) We leave it to the reader to go through the dull task of verifying that the given recipe defines an orientation on $X \cap Y$.

(ii) In the Transversal Preimage Theorem 42.3 (3b) we will prove a generalization of this statement. The proof is a little delicate. To avoid lengthy repetitions we refer the reader to the later argument.

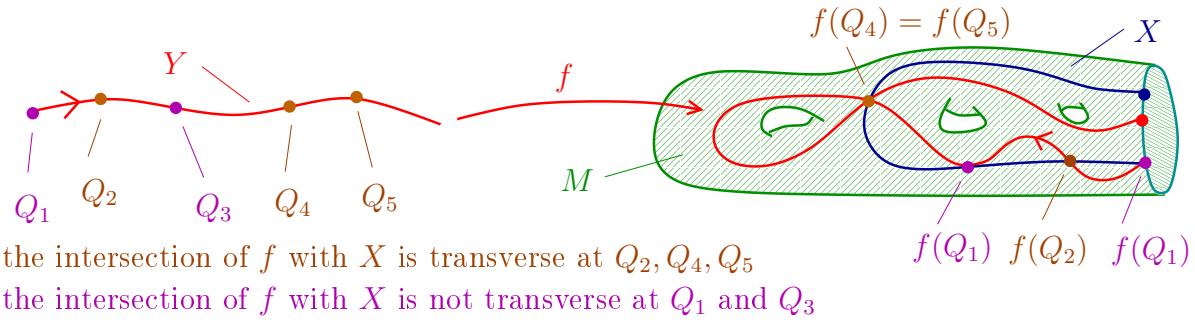
(d) By symmetry we can assume that Y is compact. Since X is a proper submanifold of M it is in particular a closed subset of M. By definition of the subspace topology on Y we see that $X \cap Y$ is a closed subset of the compact space Y. By the Compact-Closed Lemma 1.21 (1) this implies that $X \cap Y$ itself is compact. ■

42.2. **The Transversal Preimage Theorem.** The following definition can be viewed as generalization of the definition from page 968.

Definition. Let M be a smooth manifold and let X be a proper submanifold of M. Let Y be some other smooth manifold and let $f\colon Y \to M$ be a smooth map such that $f^{-1}(\partial M)$ is a union of components of ∂Y.

(1) Let $Q \in Y$ with $f(Q) \in X$. We say X intersects f transversally in Q if

$$\mathrm{D}f_Q(\mathrm{T}_Q Y) + \mathrm{T}_{f(Q)} X \;=\; \mathrm{T}_{f(Q)} M.$$



If $Q \in \partial Y$ then we also demand that $f(Q) \in \partial M$ and that [410]

$$\mathrm{D}f_Q(\mathrm{T}_Q(\partial Y)) + \mathrm{T}_{f(Q)}(\partial X) \;=\; \mathrm{T}_{f(Q)}(\partial M).$$

(2) Let C be a subset of Y. We say X intersects f transversally on C if for every $Q \in C$ with $f(Q) \in X$ the submanifold X intersects the map f transversally in Q.

(3) We say X intersects f transversally if for every $Q \in Y$ with $f(Q) \in X$ the submanifold X intersects the map f transversally in Q.

(4) We abbreviate the expression "X intersects f transversally" by $X \pitchfork f$.

Examples.

(1) Let M be a smooth manifold and let X and Y be two proper submanifolds of M. We denote by $i\colon Y \to M$ the inclusion map. It follows immediately from the definitions that i intersects X transversally if and only if X intersects Y transversally in the sense of the definition on page 968.

(2) Let Y and M be smooth manifolds and let $f\colon Y \to M$ be a smooth map. Furthermore let $x \in M \setminus \partial M$. By definition the map f is transverse to the 0-dimensional submanifold $\{x\}$ if and only if x is a regular value of f, as defined on page 701.

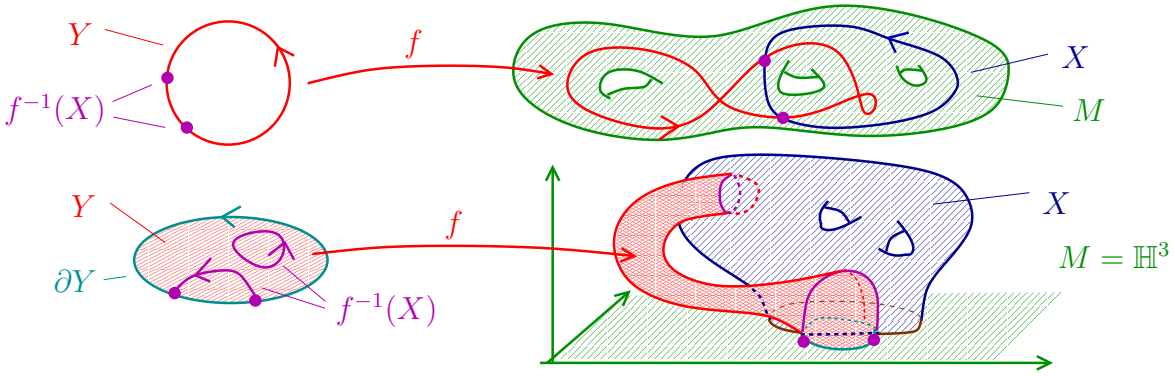
The following theorem might ring a bell. Considering the above examples we see that it is quite close to the statement of the Submanifold Transversal Intersection Theorem 42.1 (2) and to the statement of the Regular Value Theorem 26.4.

Theorem 42.3. (Transversal Preimage Theorem) Let M be a smooth manifold and let X be a proper submanifold of M of codimension l. Furthermore let Y be some other smooth manifold and let $f\colon Y \to M$ be a smooth map such that $f^{-1}(X \setminus \partial X) \subset Y \setminus \partial Y$ and such that $f^{-1}(\partial M)$ is a union of components of ∂Y. We denote by $f_\partial\colon \partial Y \to \partial M$ the restriction of f to ∂Y. If X intersects f transversely, i.e. if $X \pitchfork f$, then the following statements hold:

(1) The preimage $f^{-1}(X)$ is a proper submanifold of Y of codimension l where the boundary $\partial(f^{-1}(X))$ is given by $(f_\partial)^{-1}(X) = (f_\partial)^{-1}(\partial X)$.

(2) For every $P \in f^{-1}(X)$ we have

$$\mathrm{T}_P(f^{-1}(X)) \;=\; (\mathrm{D}f_P)^{-1}(\mathrm{T}_{f(P)}X).$$



(3) Let M, X and Y be oriented. Furthermore let $P \in Y$.

(a) By hypothesis the homomorphism $\mathrm{D}f_P\colon \mathrm{T}_PY \to \mathrm{T}_{f(P)}M$ intersects T_PX transversally. Thus we can equip $\mathrm{T}_P(f^{-1}(X)) \;=\; (\mathrm{D}f_P)^{-1}(\mathrm{T}_{f(P)}X)$ with the preimage orientation that we introduced on page 673. These orientations define an orientation on the smooth manifold $f^{-1}(X)$.

(b) The equality $\partial(f^{-1}(X)) = (f_\partial)^{-1}(\partial X)$ is an equality of oriented smooth manifolds.[411]

[410] If $Q \in \partial Y$ with $f(Q) \in \partial X$, then by hypothesis the component C of ∂Y that contains Q satisfies $f(C) \subset \partial M$. It follows from the hypothesis that f is smooth together with the Smooth Manifold Boundary Proposition 19.26 (2a) and (2c) that f restricts to a smooth map $f\colon C \to \partial M$. Thus we obtain that $\mathrm{D}f_Q(\mathrm{T}_Q(\partial Y)) = \mathrm{D}f_Q(\mathrm{T}_Q C)$ is a vector subspace of $\mathrm{T}_{f(Q)}(\partial M)$.

(4) If Y is compact, then so is $f^{-1}(X)$.

Remark.

(1) The preimage orientation that we introduced on page 673 is defined via the following diagram

$$\begin{array}{ccccc} \mathrm{T}_{f(P)}X & \hookrightarrow & \mathrm{T}_{f(P)}M & \twoheadrightarrow & \mathrm{T}_{f(P)}M/\mathrm{T}_{f(P)}X \\ & & & & \cong\uparrow{\scriptstyle [v]\mapsto[\mathrm{D}f_P(v)]} \\ \mathrm{T}_P(f^{-1}(X)) & \hookrightarrow & \mathrm{T}_PY & \twoheadrightarrow & \mathrm{T}_PY/\mathrm{T}_P(f^{-1}(X)). \end{array}$$

The orientation on $\mathrm{T}_P(f^{-1}(X))$ is the unique orientation that makes the orientations in the short exact sequences compatible[412] and the right vertical map orientation-preserving.

(2) Let X and Y be proper submanifolds of a smooth submanifold M. If we apply the Transversal Preimage Theorem 42.3 to the inclusion $i\colon Y \to M$, then we see that $i^{-1}(X) = X \cap Y$ is a proper submanifold of Y. It follows from an elementary argument, see Exercise 19.31 (a), that $i^{-1}(X)$ is also a proper submanifold of M. This discussion shows that we can recover the statement of the Submanifold Transversal Intersection Theorem 42.1 (2) from the Transversal Preimage Theorem 42.3.

(3) Suppose that in the setting of the Transversal Preimage Theorem 42.3 the submanifold X consists of a single point $\{x\}$. We equip this 0-dimensional manifold with the orientation given by $+1$. Inspecting the definitions one sees that the preimage orientation on $f^{-1}(x)$ that we just introduced agrees with the orientation on $f^{-1}(x)$ that we introduced in the Regular Value Theorem 26.4 (3).

Proof. Let M be an m-dimensional smooth manifold and let X be a proper submanifold of M of codimension l. Let Y be some other smooth manifold and let $f\colon Y \to M$ be a smooth map such that $f^{-1}(X \setminus \partial X) \subset Y \setminus \partial Y$ and such that $f^{-1}(\partial M)$ is a union of components of ∂Y.

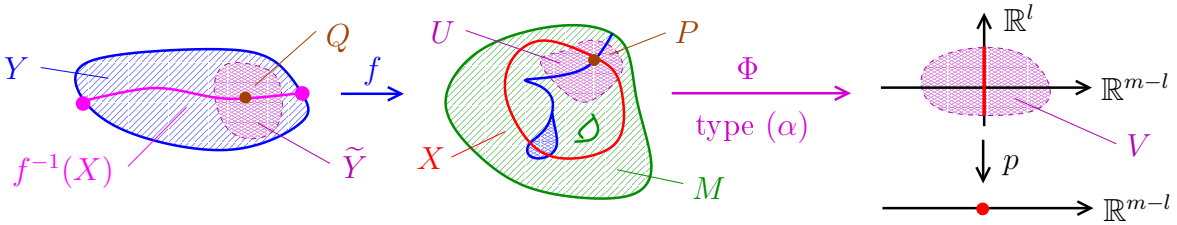
(1) We need to show that the preimage $f^{-1}(X)$ is a proper submanifold of Y of codimension l with boundary $\partial(f^{-1}(X)) = (f_\partial)^{-1}(\partial X)$. First note that X is a closed subset

[411] It takes a while to figure out what orientations we are talking about. We give $f^{-1}(X)$ the orientation from (3a) and we give $\partial(f^{-1}(X))$ the boundary orientation from page 689. Furthermore we equip ∂X, ∂Y and ∂M with the boundary orientations. By definition of transverse intersection we also have $\partial X \pitchfork f_\partial$. Thus $(f_\partial)^{-1}(\partial(X))$ is a proper submanifold of ∂Y and we use (3a) to equip $(f_\partial)^{-1}(\partial X)$ with an orientation.

[412] We refer to page 671 for the definition of compatible orientations.

of M since X is a proper submanifold. Therefore $f^{-1}(X)$ is a closed subset of Y. Furthermore note that it follows from our hypothesis that X is a proper submanifold of M and our hypotheses on $f^{-1}(X\backslash\partial X)$ and on $f^{-1}(\partial M)$ that $(f_\partial)^{-1}(\partial X) = f^{-1}(X)\cap\partial Y$. Thus it remains to show that every point Q in $f^{-1}(X)$ admits a submanifold chart of type (α) or of type (β). To prove this statement it suffices to show that every point Q in $f^{-1}(X)$ admits an open neighborhood $\widetilde{Y} \subset Y$ such that $f^{-1}(X)\cap\widetilde{Y}$ is a proper submanifold of $\widetilde{Y}$.

Let $Q \in f^{-1}(X)$. We set $P := f(Q) \in X$. We need to distinguish the two cases that $P \in X \setminus \partial X$ and that $P \in \partial X$.

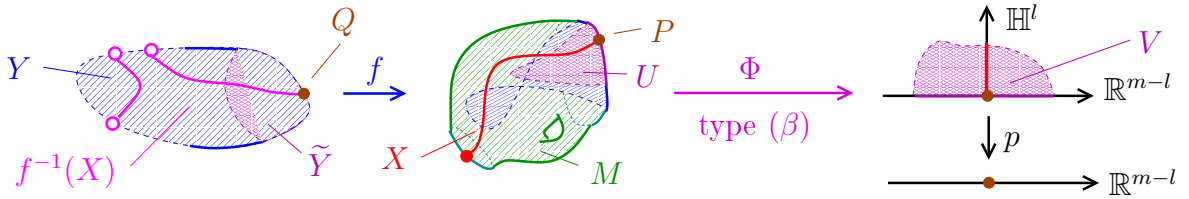


(a) First we consider the case that $P \in X \setminus \partial X$. In this case it follows from the hypothesis that X is a proper submanifold of M that there exists a submanifold chart $\Phi\colon U \to V$ of type (α) around P such that $\Phi(P) = 0$.
Since we assume that $f^{-1}(X \setminus \partial X) \subset Y \setminus \partial Y$ we see that $\widetilde{Y} := f^{-1}(U)\cap(Y \setminus \partial Y)$ is an open neighborhood of Q. Now it suffices to prove the following claim.

Claim. The subset $f^{-1}(X)\cap\widetilde{Y}$ is a proper submanifold of $\widetilde{Y}$.

Proof. We write $\widetilde{f} := f|_{\widetilde{Y}}$. Since Φ is a submanifold chart of type (α) we know that we have $\Phi(X\cap U) = \{0\}\times\mathbb{R}^l$. We denote by $p\colon \mathbb{R}^m = \mathbb{R}^{m-l}\times\mathbb{R}^l \to \mathbb{R}^{m-l}$ the natural projection. Note that

$$f^{-1}(X)\cap\widetilde{Y} \;=\; \widetilde{f}^{-1}(X)\cap\widetilde{Y} \;=\; \widetilde{f}^{-1}(X\cap U) \;=\; (p\circ\Phi\circ\widetilde{f})^{-1}(0).$$



Note that the Regular Value Theorem 26.4 says that $(p\circ\Phi\circ\widetilde{f})^{-1}(0)$ is a proper submanifold of $\widetilde{Y}$ if 0 is a regular value of $p\circ\Phi\circ\widetilde{f}\colon \widetilde{Y} \to \mathbb{R}^{m-l}$. So it remains to show that 0 is a regular value of $p\circ\Phi\circ\widetilde{f}\colon \widetilde{Y} \to \mathbb{R}^{m-l}$. By definition of a regular value we need to show that each $Q' \in \widetilde{Y}$ is a regular point of $p\circ\Phi\circ\widetilde{f}$. By our clever choice of $\widetilde{Y}$ we know that $Q' \notin \partial\widetilde{Y}$. Therefore we only need to show that $\mathrm{D}(p\circ\Phi\circ\widetilde{f})^{-1}_{Q'}\colon \mathrm{T}_{Q'}\widetilde{Y} \to \mathrm{T}_0\mathbb{R}^{m-l}$ is an epimorphism. The fact that this map is indeed an epimorphism follows easily from our hypothesis that f is transverse to X together with Lemma 42.2. ⊞

(b) Now we consider the case that $P \in \partial X$. In this case it follows from the hypothesis that X is a proper submanifold of M that there exists a submanifold chart $\Phi\colon U \to V$ of type (β) around P such that $\Phi(P) = 0$. By our hypothesis on $f^{-1}(\partial M)$ we know that there exists a component C of ∂Y with $C \in \partial Y$ and with $f(C) \subset \partial M$. By the Smooth Manifold Boundary Proposition 19.26 we know that $\partial M \setminus C$ is a closed subset. Thus we see that $\widetilde{Y} := (f^{-1}(U)) \cap (M \setminus (\partial M\backslash))$ is an open neighborhood of Q. Now it suffices to prove the following claim.

Claim. The subset $f^{-1}(X) \cap \widetilde{Y}$ is a proper submanifold of $\widetilde{Y}$ with boundary $(f_\partial)^{-1}(\partial X) \cap \widetilde{Y}$.

Proof. We write $\widetilde{f} := f|_{\widetilde{Y}}$. Since Φ is a submanifold chart of type (β) we know that V is an open subset of $\mathbb{H}^m$ and that $\Phi(X \cap U) = \{0\} \times \mathbb{H}^l$. As in the previous claim we need to show that each $Q' \in \widetilde{Y}$ is a regular point of $p \circ \Phi \circ \widetilde{f}$.
Let $Q' \in \widetilde{Y}$. It follows as before that $\mathrm{D}(p \circ \Phi \circ \widetilde{f})^{-1}_{Q'} \colon \mathrm{T}_{Q'}\widetilde{Y} \to \mathrm{T}_0\mathbb{R}^{m-l}$ is an epimorphism. Now assume that $Q' \in \partial\widetilde{Y}$. From the definition of $\widetilde{Y}$ we see that $Q' \in C$, in particular $Q' \in \partial Y$ and $f(Q') \in \partial M$. It follows from the definition on page 971, that $\mathrm{D}(p \circ \Phi \circ \widetilde{f})^{-1}_{Q'} \colon \mathrm{T}_{Q'}(\partial\widetilde{Y}) \to \mathrm{T}_0\mathbb{R}^{m-l}$ is also an epimorphism. Thus we see that Q' satisfies all the conditions of a regular point as laid out on page 701. ⊞

(2) Let $Q \in f^{-1}(X)$. Evidently we have $(\mathrm{D}f_{f(Q)})^{-1}(\mathrm{T}_Q(f^{-1}(X))) \subset \mathrm{T}_{f(Q)}(X)$, which implies that $\mathrm{T}_Q(f^{-1}(X)) \subset (\mathrm{D}f_{f(Q)})^{-1}(\mathrm{T}_{f(Q)}(X))$. Both sides are vector spaces of dimension $m-k-l$, which implies that equality holds.

(3) (a) We leave the verification of this statement to the reader.

(b) We need to show that the two orientations on $\partial(f^{-1}(X)) = (f_\partial)^{-1}(\partial X)$ agree. Thus let $P \in \partial f^{-1}(X)$ we write $Q = f(P)$. For orientation it might help to consider the following diagram

$$\begin{array}{ccccc}
\mathrm{T}_Q X & \longrightarrow & \mathrm{T}_Q M & \longrightarrow & \mathrm{T}_Q M/\mathrm{T}_Q X \\
 & & & & \uparrow{\scriptstyle \mathrm{D}f_P} \\
\mathrm{T}_P(f^{-1}(X)) & \longrightarrow & \mathrm{T}_P Y & \longrightarrow & \mathrm{T}_P Y/\mathrm{T}_P(f^{-1}(X)) \\
\uparrow & & \uparrow & & \uparrow{\scriptstyle \cong} \\
\mathrm{T}_P((f_\partial)^{-1}(\partial X)) & \longrightarrow & \mathrm{T}_P(\partial Y) & \longrightarrow & \mathrm{T}_P(\partial Y)/\mathrm{T}_P((f_\partial)^{-1}(\partial X))
\end{array}$$

In the following we make a few preparations.

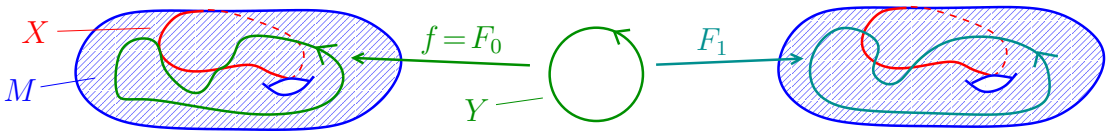
(i) The orientations on $\mathrm{T}_Q X$ and $\mathrm{T}_Q M$ define an orientation on $\mathrm{T}_Q M/\mathrm{T}_Q X$. We pick vectors $v_1, \dots, v_l \in \mathrm{T}_Q M/\mathrm{T}_Q X$ which represent this orientation.

(ii) We pick $\widetilde{v}_1, \dots, \widetilde{v}_l \in \mathrm{T}_P Y$ such that $\mathrm{D}f_P(\widetilde{v}_i) = v_i$ for $i = 1, \dots, l$.

We use the following orientations:

$\mathrm{T}_P(f^{-1}(X))$	with the orientation from (3a) applied to $f \colon Y \to M$
$\mathrm{T}_P(\partial(f^{-1}(X)))$	with the boundary orientation from page 689
$\mathrm{T}_P((f_\partial)^{-1}(X))$	with the orientation from (3a) applied to $f_\partial \colon \partial Y \to M$
$\mathrm{T}_P Y$	with the given orientation
$\mathrm{T}_P(\partial Y)$	with the boundary orientation from page 689.

To simplify the notation we view $\mathrm{T}_P(f^{-1}(X))$ as a vector subspace of $\mathrm{T}_P Y$. We pick an outward pointing vector $o \in \mathrm{T}_P(f^{-1}(X))$. It follows from Exercise 23.8 that o, viewed as a vector in $\mathrm{T}_P Y$, is also outward pointing. Now let $u_1, \dots, u_d$ be a basis of $\mathrm{T}_P(\partial(f^{-1}(X))) = \mathrm{T}_P(f_\partial)^{-1}(\partial X)$. We see:



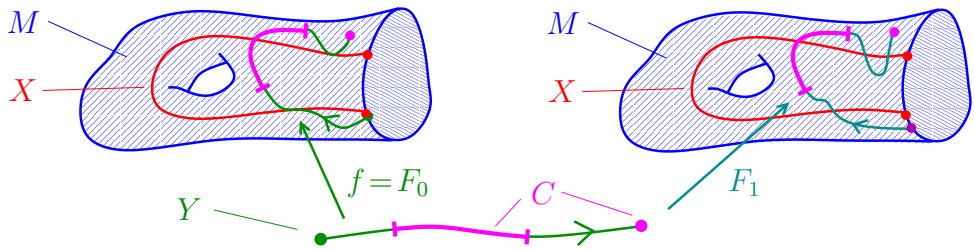
$$\begin{array}{lll} & u_1, \dots, u_d & \text{is a positive basis of } \mathrm{T}_P\left(\partial(f^{-1}(X))\right) \\ \iff & o, u_1, \dots, u_d & \text{is a positive basis of } \mathrm{T}_P(f^{-1}(X)) \\ \iff & o, u_1, \dots, u_d, \widetilde{v}_1, \dots, \widetilde{v}_l & \text{is a positive basis of } \mathrm{T}_P Y \\ \iff & u_1, \dots, u_d, \widetilde{v}_1, \dots, \widetilde{v}_l & \text{is a positive basis of } \mathrm{T}_P\left(\partial Y\right) \\ \iff & u_1, \dots, u_d & \text{is a positive basis of } \mathrm{T}_P((f_\partial)^{-1}(\partial X)). \end{array}$$

(4) Suppose that Y is compact. Since X is a proper submanifold of M it is in particular a closed subset of M. Therefore $f^{-1}(X)$ is a closed subset of the compact space Y. By the Compact-Closed Lemma 1.21 (1) this implies that $f^{-1}(X)$ itself is compact. ■

42.3. **The Transversality Theorem.** Our goal of this section is to state the Transversality Theorem. For the reader's convenience we first state a simplified version before we state the bells-and-whistles version.

Theorem 42.4. (Transversality Theorem) Let M be a smooth manifold with $\partial M = \varnothing$ and let X be a proper submanifold of M. Furthermore let Y be a compact smooth manifold and let $f\colon Y \to M$ be a smooth map.

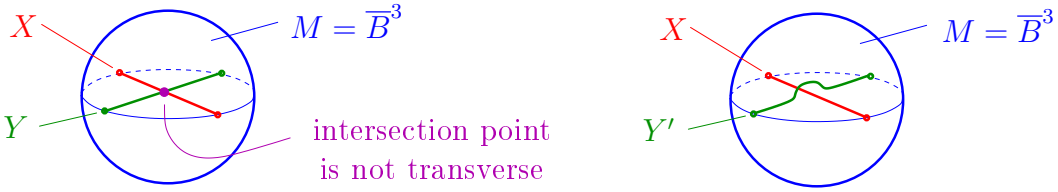
(1) There exists a smooth homotopy F from $F_0 = f\colon Y \to M$ to a map $F_1\colon Y \to M$ that is transverse to X.
(2) If f is a smooth embedding, then we can choose F to be a smooth isotopy.



We postpone the proof of the Transversality Theorem 42.4 to Section 42.4. We move straight on to a more general statement.

Theorem 42.5. (Transversality Theorem II) Let M be a smooth manifold and let X be a proper submanifold of M. Furthermore let Y be a compact smooth manifold and let $f\colon Y \to M$ be a smooth map such that $f^{-1}(\partial M)$ is a union of components of ∂Y. We assume that $X \pitchfork f$ on $\partial Y \setminus f^{-1}(\partial M)$. Finally let C be a closed subset of Y such that $X \pitchfork f$ on C.

(1) There exists a smooth homotopy $F\colon Y \times [0,1] \to M$ with the following properties:
  (a) F is a smooth homotopy *rel* C from $F_0 = f$ to a map F_1 with $X \pitchfork F_1$.
  (b) The set of $t \in [0,1]$ such that $X \pitchfork F_t$ has full measure.
  (c) For each $t \in [0,1]$ we have $F_t^{-1}(\partial M) = f^{-1}(\partial M)$.[413]
(2) If f is a smooth embedding, then we can choose F to be a smooth isotopy.



Remark.

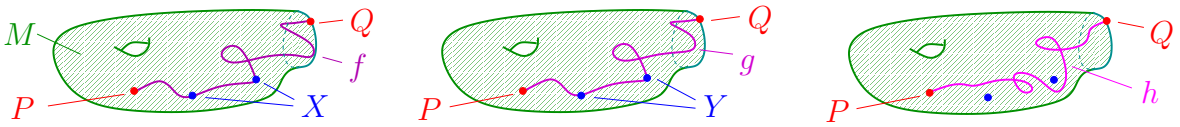
[413] In particular if f is proper, i.e. if $f^{-1}(\partial M) = \partial Y$, then for each t we have $F_t^{-1}(\partial M) = \partial Y$, i.e. each F_t is proper.

(1) Similar statements are also proved in [**Lee2002**, Theorem 6.36] and [**GP1974**, p. 70]. Most statements of the theorem also follow from Proposition 4.4.4, Theorem 4.5.6 and Proposition 4.5.7 of [**Wall2016**].[414]
(2) For many purposes the Avoid-Tubular Neighborhoods Proposition **??** can be a useful variation on the Transversality Theorem 42.4.

Example. Let M be a smooth manifold. Furthermore let X and Y be two proper submanifolds of M. If $\dim(X)+\dim(Y) < \dim(M)$, then one deduces easily from the definitions that X and Y intersect transversally if and only if X and Y are disjoint. With this observation the Transversality Theorem 42.4 (2) says in particular that any two proper 1-dimensional submanifolds X and Y of the 3-dimensional ball $\overline{B}^3$ can be made disjoint after a smooth isotopy. If the boundaries are already disjoint, then we can apply the Transversality Theorem 42.4 (2) with $C = \partial Y$ and we see that can make X and Y disjoint while keeping X and the boundary of Y fixed.

The following is a typical and often used consequence of the above transversality theorems.

Corollary 42.6. Let M be a connected n-dimensional smooth manifold and let X be a proper k-dimensional smooth submanifold of M. If $k \leq n-2$, then $M \setminus X$ is path-connected.



Proof. Let $P, Q \in M \setminus X$. Since M is connected we know by the Smooth Path-Connectivity Proposition 19.29 that there exists a smooth map $f\colon [0,1] \to M$ with $f(0) = P$ and $f(1) = Q$.

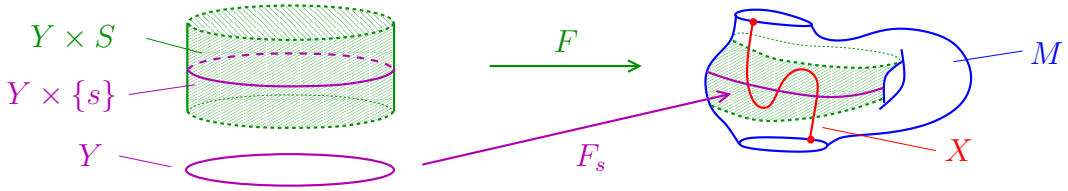
Using the Smooth Collar Neighborhood Theorem 28.3 one can show, see Exercise 28.5, that there exists in fact a smooth path $g\colon [0,1] \to M$ with $g(0) = P$ and $g(1) = Q$ and with $g^{-1}(\partial M) \subset \{0,1\}$.

Note that the fact that $P, Q \in M \setminus X$ implies that $X \pitchfork f$ on $\partial[0,1] = \{0,1\}$. Thus we can apply the Transversality Theorem 42.5 to the closed subset $C = \{0,1\}$ and we obtain a smooth map $h\colon [0,1] \to M$ with $h(0) = g(0) = f(0) = P$ and $h(1) = g(1) = f(1) = Q$ and

[414] A first look at [**Wall2016**, Theorem 4.5.6] might be slightly confusing since it demands that X is a "submanifold of $J^r(M,N)$" for some $r \in \mathbb{N}_0$. But as is explained on page 101 of [**Wall2016**], we have $J^0(M,Y) = M \times Y$, and $X \times \{*\}$ is clearly a submanifold of $M \times Y$ for any $* \in Y \setminus \partial Y$.

such that $X \pitchfork h$. But since $\dim(X) + \dim([0,1]) < \dim(M)$ the last condition just says that $X \cap h([0,1]) = \varnothing$. In other words, h is a path in $M \setminus X$ that connects P and Q. ■

We now turn to the proofs of the Transversality Theorems. In Section 42.4 we provide the proof of the Transversality Theorem 42.4. This proof has a neat idea and is quite readable. Afterwards in Section 42.5 we provide the proof of the Transversality Theorem 42.5. This proof is much more technical and arguably much less fun for the author and the reader.



42.4. **Proof of the Transversality Theorem 42.4.** First we introduce or recall the following easy-to-digest notation.

Notation. Let $Y \times S \to M$ be a map. For each $s \in S$ we set

$$\begin{array}{rccc} F_s\colon & Y & \to & M \\ & y & \mapsto & F(y,s). \end{array}$$

The proofs of the Transversality Theorems 42.4 and 42.5 rest on the following proposition.

Proposition 42.7. (Parametric Transversality Proposition) Let Y and M be smooth manifolds and let $X \subset M$ be a proper smooth submanifold. Furthermore let S be a smooth manifold with empty boundary. Finally let $F\colon Y \times S \to M$ be a proper smooth map. If $F\colon Y \times S \to M$ is transverse to X, then for almost every[415] $s \in S$ the map $F_s\colon Y \to M$ is also transverse to X.

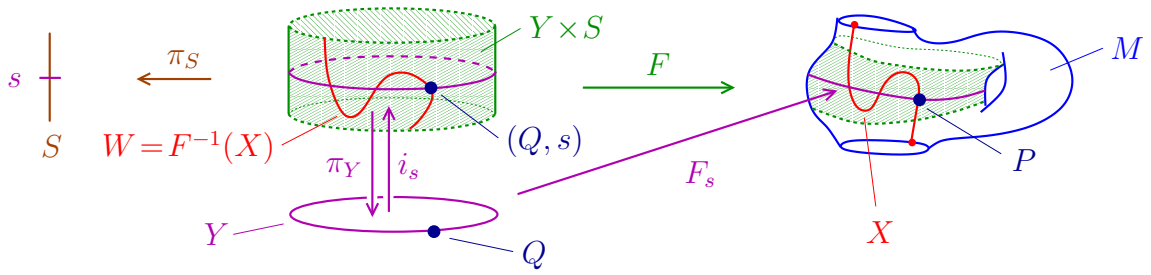
Proof of the Parametric Transversality Proposition 42.7. Since $F\colon Y \times S \to M$ is transverse to the proper submanifold $X \subset M$ we obtain from the Transversal Preimage Theorem 42.3 that $W := F^{-1}(X)$ is a submanifold of $Y \times S$. Let $\pi_S\colon Y \times S \to S$ be the obvious projection. By Sard's Theorem 31.1 we know that the set of regular values of the smooth maps $\pi_S\colon W \to S$ and $\pi_S\colon \partial W = \partial Y \times S \to S$ have full measure. Thus, according to the definition on page 971, it suffices to show the following claim.

Claim.

(1) If $s \in S$ is a regular value of $\pi_S|_W\colon W \to S$, then for any $Q \in Y$ with $F_s(Q) \in X$ we have $\mathrm{T}_{F_s(Q)}X + \mathrm{D}(F_s)_Q(\mathrm{T}_Q Y) = \mathrm{T}_{F_s(Q)}M$.

(2) If $s \in S$ is a regular value of $\pi_S|_{\partial W}\colon \partial W \to S$, then for any $Q \in \partial Y$ with $F_s(Q) \in \partial X$ we have $\mathrm{T}_{F_s(Q)}\partial X + \mathrm{D}(F_s)_Q(\mathrm{T}_Q \partial Y) = \mathrm{T}_{F_s(Q)}\partial M$.

[415] Recall that, according to the definition on page 762, the expression "almost every" means that the set of points $s \in S$ for which F_s is transverse to X has full measure.



In other words, if $s \in S$ is a regular value of $\pi_S|_W \colon W \to S$ and if $s \in S$ is a regular value of $\pi_S|_{\partial W} \colon \partial W \to S$, then $F_s \colon Y \to M$ is transverse to X.

Proof. We prove Statement (1). The proof of Statement (2) is basically identical. Thus let $s \in S$ be a regular value of $\pi_S|_W \colon W \to S$ and let $Q \in F_s^{-1}(X)$. We set $P := F_s(Q) \in X$. We need to show that $\mathrm{T}_P X + \mathrm{D}(F_s)_Q(\mathrm{T}_Q Y) = \mathrm{T}_P M$. We consider the following diagram

$$\begin{array}{ccccc}
\mathrm{T}_{(Q,s)}W \oplus \mathrm{T}_{(Q,s)}(Y \times \{s\}) & \xrightarrow{\cong} & \mathrm{T}_{(Q,s)}(Y \times S) & \xrightarrow{\mathrm{D}(\pi_Y)_{(Q,s)} \oplus \mathrm{D}(\pi_S)_{(Q,s)}} & \mathrm{T}_Q Y \oplus \mathrm{T}_s S \\
\downarrow{\scriptstyle \mathrm{D}F_{(Q,s)}} & & \downarrow{\scriptstyle \mathrm{D}F_{(Q,s)}} & & \downarrow{\scriptstyle \mathrm{D}F_{(Q,s)}} \\
\mathrm{T}_P X \oplus \mathrm{D}(F_s)_Q(\mathrm{T}_Q Y) & & \longrightarrow & & \mathrm{T}_P M \\
\uparrow{\scriptstyle \mathrm{D}(F_s)_Q} & & & & \downarrow \\
\mathrm{T}_Q Y & & \xrightarrow{\mathrm{D}(F_s)_Q} & & \mathrm{T}_P M / \mathrm{T}_P X.
\end{array}$$

We make the following clarifications and observations:

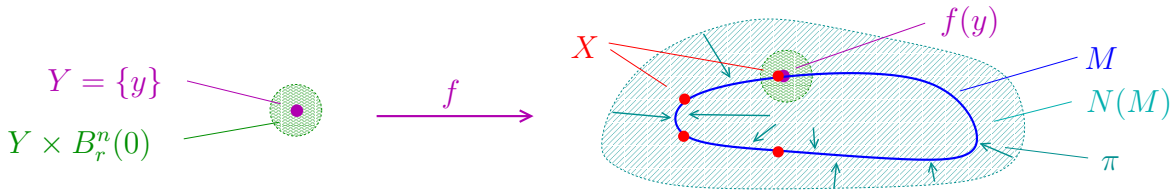
(1) The top right horizontal map is induced by the projection $\pi_Y \colon Y \times S \to Y$ and the projection $\pi_S \colon Y \times S \to S$.
(2) The undecorated maps are either given by inclusion maps or the natural projections.
(3) It is clear that the diagram commutes.
(4) Since s is a regular value of $\pi_S|_W \colon W \to S$ one sees easily that the composition of the top two horizontal maps is an epimorphisms. Since all vector spaces on the top row are of the same dimension we see that the horizontal map to the top left is actually an isomorphism.
(5) Recall that by hypothesis the map $F \colon Y \times S \to M$ is transverse to X. Thus we know that $\mathrm{T}_P X + \mathrm{D}F_{(Q,s)}(\mathrm{T}_{(Q,s)}(Y \times S)) = \mathrm{T}_P M$. This implies that the composition of the middle two vertical maps is an epimorphism.
(6) By the Transversal Preimage Theorem 42.3 we have $\mathrm{T}_{(Q,s)}W = (\mathrm{D}F_{(Q,s)})^{-1}(\mathrm{T}_P X)$, which implies that $\mathrm{D}F_{(Q,s)}(\mathrm{T}_{(Q,s)}W) \subset \mathrm{T}_P X$.
(7) Evidently we have $\mathrm{D}F_{(Q,s)}(\mathrm{T}_{(Q,s)}(Y \times \{s\})) = \mathrm{D}(F_s)_Q(\mathrm{T}_Q Y)$.
(8) It follows from the above that the map $\mathrm{D}(F_s) \colon \mathrm{T}_Q Y \to \mathrm{T}_P M / \mathrm{T}_P X$ is an epimorphism. But that implies of course that $\mathrm{T}_P X + \mathrm{D}(F_s)_Q(\mathrm{T}_Q Y) = \mathrm{T}_P M$, which is exactly what we needed to show. ∎

Proof of the Transversality Theorem 42.4. Let M be a smooth manifold such that $\partial M = \varnothing$ and let X be a proper submanifold of M. Furthermore let Y be a compact smooth manifold and let $f \colon Y \to M$ be a smooth map. First we need to show that there

exists a smooth homotopy F from $F_0 = f\colon Y \to M$ to a map $F_1\colon Y \to M$ that is transverse to X. To do so, we make the following preparations:

(1) By the Euclidean Embedding Theorem 27.1 and the Smooth Embedding Theorem 24.10 we can assume that M is a proper smooth submanifold of some $\mathbb{R}^n$.
(2) By the Neighborhood Projection Theorem 28.1 there exists an open neighborhood $N(M)$ of $M \subset \mathbb{R}^n$ and a smooth map $\pi\colon N(M) \to M$ which has the following two properties:
   (a) π is a retraction,
   (b) π is a submersion, i.e. for each $Q \in N(M)$ the differential $\mathrm{D}\pi_Q$ is an epimorphism.

Since Y is compact we obtain from the Compact Image Lemma 2.13 together with the elementary Exercise 6.1 that there exists an $r > 0$ such that for each $y \in Y$ we have $B^n_r(f(y)) \subset N(M)$. Therefore we can consider the map



$$\begin{array}{rcl} F\colon Y \times B^n_r(0) & \to & M \\ (y, v) & \mapsto & \pi(f(y) + v). \end{array}$$

Evidently the map $Y \times B^n_r(0) \to N(M)$ given by $(y, v) \mapsto f(y) + v$ is a submersion. Furthermore by (2b) we know that $\pi\colon N(M) \to M$ is a submersion. This discussion shows that for each $(y, v) \in Y \times B^n_r(0)$ the map $\mathrm{D}F_{(y,v)}$ is an epimorphism. This implies that $F\colon Y \times B^n_r(0) \to M$ is transverse to X.

By the Parametric Transversality Proposition 42.7 there exists a $v \in B^n_r(0)$ such that $F_v\colon Y \to M$ is transverse to X. The desired smooth homotopy is now given by the map

$$\begin{array}{rcl} H\colon Y \times [0,1] & \to & M \\ (y, t) & \mapsto & F_{t\cdot v}(y) = F(y, t \cdot v) = \pi(f(y) + t \cdot v). \end{array}$$

Now assume that f is a smooth embedding. Since $F_0 = f$ it follows from the Deform Smooth Embedding Proposition 33.6 (1) that, after possibly shrinking r, we can assume that for each $v \in B^n_r(0)$ the map $F_v\colon Y \to M$ is a smooth embedding. In this setting the above map H is now actually a smooth isotopy. ∎

42.5. **Proof of the Transversality Theorem 42.5.** In hindsight the proof of the Transversality Theorems 42.4 was not all that bad. The proof of the considerably more elaborate Transversality Theorem 42.5 will be, well, considerably more elaborate.

We start out with the following lemma, which is of independent interest.

Lemma 42.8. Given any $m, n, r \in \mathbb{N}_0$ the set

$$\{A \in \mathrm{M}(m \times n, \mathbb{R}) \mid \mathrm{rank}(A) \geq r\}$$

is an open subset of $\mathrm{M}(m \times n, \mathbb{R})$.

Remark. Lemma 42.8 is a slight generalization of Exercise 2.41.

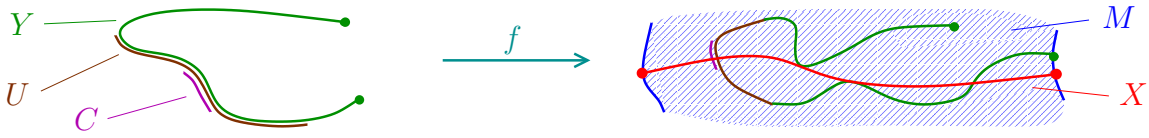
Proof. Given $I \subset \{1,\dots,m\}$ and $J \subset \{1,\dots,n\}$ with $\#I = r$ and $\#J = r$ we consider the map

$$\begin{array}{rccl} \det_{I,J}\colon & \mathrm{M}(m\times n,\mathbb{R}) & \to & \mathbb{R} \\ & A=(a_{ij}) & \mapsto & \text{determinant of the } r\times r\text{-matrix } (a_{ij})_{i\in I, j\in J}. \end{array}$$

It follows from the Leibniz formula that $\det_{I,J}$ is continuous. Using this notation we can formulate the following claim.

Claim. Let $A = (a_{ij}) \in \mathrm{M}(m \times n, \mathbb{R})$. The following two statements are equivalent:

(1) $\mathrm{rank}(A) \geq r$.
(2) There exist subsets $I \subset \{1,\dots,m\}$ and $J \subset \{1,\dots,n\}$ with $\#I = r$ and $\#J = r$ such that $\det_{I,J}(A) \neq 0$.



Proof. We leave it to the reader to pull out their favorite linear algebra book and to prove the claim. ⊞

It follows from the claim that

$$\{A \in \mathrm{M}(m\times n,\mathbb{R}) \mid \mathrm{rank}(A) \geq r\} \;=\; \bigcup_{\substack{I,J \text{ with} \\ \#I=r \text{ and } \#J=r}} (\det_{I,J})^{-1}(\mathbb{R}\setminus\{0\}).$$

Since each $\det_{I,J}$ is continuous we see that the set to the left is indeed open. ■

Lemma 42.9. (Transversality-Extends-to-Neighborhood Lemma) Let M be a smooth manifold and let X be a proper submanifold of M. Furthermore let Y be a smooth manifold and let $f\colon Y \to M$ be a smooth map such that $f^{-1}(\partial M) = \partial Y$. If C is a closed subset of Y such that $X \pitchfork f$ on C, then there exists an open neighborhood U of C such that $X \pitchfork f$ on U.

Proof. It suffices to show that for each $P \in C \cap f^{-1}(X)$ there exists an open neighborhood V of $P \in Y$ such that $X \pitchfork f$ on V.

First we consider the case that $P \notin \partial Y$. After using charts of type (i) for $P \in Y$ and for $f(P) \in X$ we can assume that Y is an open subset of $\mathbb{R}^l$, that M is an open subset of $\mathbb{R}^m$ and that $X = \{0\} \times \mathbb{R}^k$. The fact that $X \pitchfork f$ on P implies that the $(m \times l + k)$-matrix

$$(\mathrm{D}f_P \; e_{m-k+1} \; \dots \; e_m)$$

has rank m. It follows from Lemma 42.8 that this condition is satisfied in an open neighborhood of P.

The case that $P \in \partial Y$ is dealt with in almost the same way. In this case we use a chart of type (ii) for $P \in \partial Y$ and for $f(P) \in \partial X$. With the same argument as above one can find an open neighborhood V_1 of $P \in Y$ that satisfies the first condition for transversality and one can find an open neighborhood V_2 of $P \in \partial Y$ that satisfies the second condition for transversality of points on the boundary. On the open neighborhood $V = V_1 \cap (M \setminus (\partial M \setminus V_2))$ we now have $X \pitchfork f$. ■

Now we turn to actual proof of the Transversality Theorem 42.5. The following lemma implies in particular the Transversality Theorem 42.5 if $\partial Y = \varnothing$.

Lemma 42.10. Let M be a smooth manifold and let X be a proper submanifold of M. Furthermore let Y be a compact smooth manifold, let $f\colon Y \to M$ be a smooth map and let C be a closed subset of Y such that $X \pitchfork f$ on C. We assume that $f^{-1}(\partial M) \subset C$.

(1) There exists a smooth homotopy F *rel* C from $F_0 = f$ to a map F_1 with $F_1 \pitchfork X$ with the following properties:
   (a) F is a smooth homotopy *rel* C from $F_0 = f$ to a map F_1 with $X \pitchfork F_1$.
   (b) The set of $t \in [0,1]$ such that $X \pitchfork F_t$ has full measure.
   (c) For each $t \in [0,1]$ we have $F_t^{-1}(\partial M) = f^{-1}(\partial M)$.[416]

(2) If f is a smooth embedding, then we can choose F to be a smooth isotopy.

Proof. Let M be a smooth manifold and let X be a proper submanifold of M. Furthermore let Y be a compact smooth manifold, let $f\colon Y \to M$ be a smooth map and let C be a closed subset of Y such that $X \pitchfork f$ on C and such that $f^{-1}(\partial M) \subset C$.

By the Transversality-Extends-to-Neighborhood Lemma 42.9 there exists an open neighborhood U of $C \subset Y$ such that $X \pitchfork f$ on U. By the Manifold Paracompact-Normal Proposition 18.9 (2) we know that Y is normal. Using the Normal-Open-Closed-Neighborhood Lemma 8.2 twice we see that there exist open subsets V, W of Y with $C \subset W \subset \overline{W} \subset V \subset \overline{V} \subset U$.

Since $\overline{V}$ and $Y \setminus U$ are disjoint closed subsets of Y we obtain from Urysohn's Lemma 21.7 for Manifolds that there exists a smooth map $\tau\colon Y \to \mathbb{R}$ with $\tau|_{\overline{V}} \equiv 0$ and $\tau|_{Y\setminus U} \equiv 1$. In the following we proceed similar to the proof on page 979.

(1) By the Euclidean Embedding Theorem 27.1 and the Smooth Embedding Theorem 24.10 we can assume that M is a proper smooth submanifold of some $\mathbb{H}^n$.

(2) By hypothesis we have $f^{-1}(\partial M) \subset C$. It follows that $f(Y \setminus W) \subset M \setminus \partial M$. Since Y is compact we know by the Compact Image Lemma 2.13 that $f(Y \setminus W)$ is a closed subset of M that is disjoint from ∂M. We now know by Exercise 28.9, which is a mild generalization of the Neighborhood Projection Theorem 28.1, that there exists an open neighborhood N of $f(Y \setminus W) \subset \mathbb{R}^n$ with $N \cap \partial M = \varnothing$ and a smooth map $\pi\colon N \to M$ which has the following two properties:
   (a) for each $P \in f(Y \setminus W)$ we have $\pi(P) = P$,
   (b) π is a submersion, i.e. for each $Q \in N(M)$ the differential $\mathrm{D}\pi_Q$ is an epimorphism.

Since $Y \setminus W$ is compact we obtain from the Compact Image Lemma 2.13 together with the elementary Exercise 6.1 that there exists an $r > 0$ such that for each $y \in f(Y \setminus W)$ we have $B_r^n(f(y)) \subset N(M)$. Therefore we can consider the map

$$\begin{array}{rcl} F\colon Y \times B_r^n(0) & \to & M \setminus \partial M \\ (y, v) & \mapsto & \begin{cases} \pi(f(y) + \tau(y) \cdot v), & \text{if } y \in Y \setminus \overline{W}, \\ y, & \text{if } y \in \overline{W}. \end{cases} \end{array}$$

Since $\tau|_{\overline{V}} \equiv 0$ we see that on the open set $V \times B_r^n(0)$ the map F is just given by the smooth map $(y, v) \mapsto y$. Furthermore by construction F is smooth on $(Y \setminus \overline{W}) \times B_r^n(0)$. Since F is smooth on open sets that cover $Y \times B_r^n(0)$ we see that F is indeed smooth.

Claim. We have $X \pitchfork F$.

Proof. Let $y \in Y$.

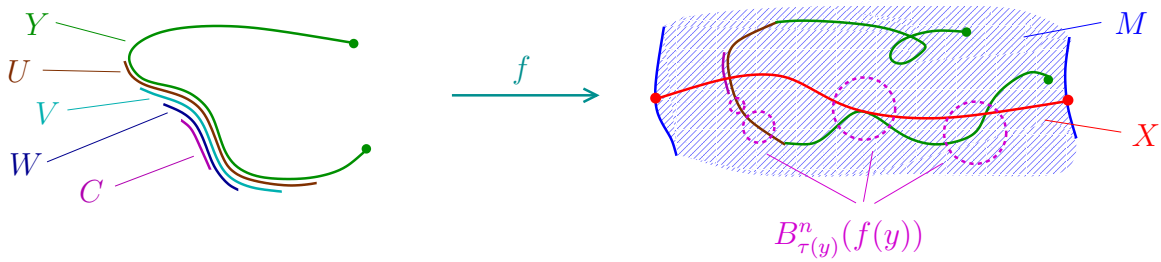
- If $\tau(y) = 0$, then by construction of τ we have $y \in U$. By the choice of U this implies that $X \pitchfork f$ at y. But since $\tau(y) = 0$ this implies that $X \pitchfork F$ at every (y, v).
- If $\tau(y) \neq 0$, then it follows from the fact that $f(y) + \tau(y) \cdot B^n_r(0) = B^n_{\tau(y)}(f(y))$ is an open neighborhood of $f(y) \in M \subset N(M) \subset \mathbb{R}^n$ and the fact that π is a submersion that for each $(y, v) \in Y \times B^n_r(0)$ the map $\mathrm{D}F_{(y,v)}$ is an epimorphism, i.e. $X \pitchfork F$ at (y, v). ⊞

The remainder of the argument is similar to the proof on page 979. By the Parametric Transversality Proposition 42.7, together with Exercise 30.2 (which is a consequence of the Mini-Fubini Lemma 30.11), there exists a $v \in B^n_r(0)$ such that $X \pitchfork F_v$, i.e. such that $F_v \colon Y \to M$ is transverse to X, and such that the following condition is satisfied:

$(*)$ The set of $t \in [0, 1]$ such that $X \pitchfork F_{t \cdot v}$ has full measure in $[0, 1]$.

Next we consider the map

$$\begin{array}{rcl} H \colon Y \times [0,1] & \to & M \\ (y, t) & \mapsto & F_{t \cdot v}(y) = F(y, t \cdot v). \end{array}$$



It remains to to verify that the map H has all the desired properties:

(a) Since F is smooth we see that H is smooth. By construction H is a homotopy from $H_0 = f$ to a map H_1 with $X \pitchfork H_1$. Note that for $y \in C$ we have, by the choice of τ, that $H(y, t) = y$ for all $t \in [0, 1]$. In other words, H is indeed a homotopy rel C.

(b) It follows from $(*)$ that the set of $t \in [0, 1]$ such that $X \pitchfork H_t$ has full measure.

(c) Since $N \cap \partial M = \varnothing$ and since $\partial M \subset C$ we see that for each $t \in [0, 1]$ we have $H_t^{-1}(\partial M) = f^{-1}(\partial M)$.

Finally assume that f is a smooth embedding. Since $F_0 = f$ it follows from the Deform Smooth Embedding Proposition 33.6 (1) that, after possibly shrinking r, we can assume that for each $s \in B^n_r(0)$ the map $F_s \colon Y \to M$ is a smooth embedding. In this setting the above map H is now actually a smooth isotopy. ■

Proof of the Transversality Theorem 42.5. Let M be a smooth manifold and let X be a proper submanifold of M. Furthermore let Y be a compact smooth manifold and let $f \colon Y \to M$ be a smooth map such that $f^{-1}(\partial M)$ is a union of components of ∂Y. To simplify the language and notation we actually assume that $f^{-1}(\partial M) = \partial Y$. Finally let C be a closed subset of Y such that $X \pitchfork f$ on C. Recall that we need to show the following:

(1) There exists a smooth homotopy $F \colon Y \times [0, 1] \to M$ with the following properties:
  (a) F is a smooth homotopy *rel* C from $F_0 = f$ to a map F_1 with $X \pitchfork F_1$.
  (b) The set of $t \in [0, 1]$ such that $X \pitchfork F_t$ has full measure.

(c) For each $t \in [0,1]$ we have $F_t^{-1}(\partial M) = \partial M$, i.e. F is a proper smooth homotopy.

(2) If f is a smooth embedding, then we can choose F to be a smooth isotopy.

We start out with the following claim.

Claim.

(1) There exists a proper smooth homotopy G rel C from f to a map $g\colon Y \to M$ such that $X \pitchfork g$ on $C \cup \partial Y$.

(2) If f is a smooth embedding, then we can choose G to be a smooth isotopy.

Proof. [417] We make the following preparations:

(a) We write $f_\partial := f|_{\partial Y}\colon \partial Y \to \partial M$.

(b) By the definition of transversality we know that the submanifold $\partial X \subset \partial M$ is transversal to the map $f_\partial\colon \partial Y \to \partial M$ on $\partial Y \cap C$.

(c) By the Transversality-Extends-to-Neighborhood Lemma 42.9 there exists an open neighborhood U of $\partial Y \cap C \subset \partial Y$ such that $f|_\partial \pitchfork f|_{\partial Y}$ on U.

(d) By the Manifold Paracompact-Normal Proposition 18.9 (2) we know that ∂Y is normal. By the Normal-Open-Closed-Neighborhood Lemma 8.2 this implies that there exists an open subset $V \subset \partial Y$ with $\partial Y \cap C \subset V \subset \overline{V} \subset U$.

(e) By the Smooth Collar Neighborhood Theorem 28.3 we can pick a collar $[0,1] \times \partial Y$ for Y and we can pick a collar $[0,1] \times \partial M$ for M.

(f) Since Y is compact, since $C \subset Y$ is closed and since $[0,1] \times \partial Y$ is closed we see that $C \cap ([0,1] \times \partial Y)$ is compact. Furthermore since $[0,1] \times \partial Y$ is a neighborhood of ∂Y and since V is a neighborhood of $C \cap \partial Y \subset \partial Y$ it follows from Exercise 5.7 that we can pick an $\epsilon > 0$ such that $C \cap ([0,\epsilon] \times \partial Y) = C \cap ([0,\epsilon] \times V)$.

(g) It follows from the Basics-of-Collars Lemma 28.4, and the compactness of ∂Y, that after possibly shrinking ϵ, we can also assume that $f([0,\epsilon]) \subset [0,1) \times \partial M$.

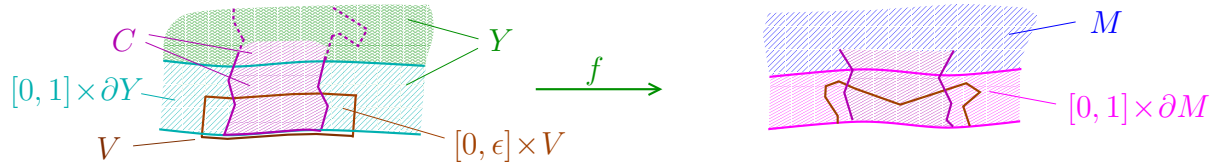
(h) We denote by $\pi\colon [0,1] \times \partial M \to [0,1]$ the projection onto the first factor.

(i) By the Smooth Transition Function Lemma 19.4 we can pick a smooth function $\eta\colon [0,\epsilon] \to \mathbb{R}$ such that $\eta(0) = 0$ and $\eta(t) = 1$ for $t \in [\frac{\epsilon}{2}, \epsilon]$ and we can pick a smooth function $\tau\colon [0,\epsilon] \to \mathbb{R}$ such that $\tau(0) = 1$ and $\tau(t) = 0$ for $t \in [\frac{\epsilon}{2}, \epsilon]$ and

Now we can provide the actual proof of the claim. Since $\partial\partial Y = \varnothing$ we know by Lemma 42.10 that there exists a smooth homotopy $F\colon \partial Y \times [0,1] \to \partial M$ rel $\partial Y \cap \overline{V}$ such that $\partial X \pitchfork F_1$ and such that the following statement holds:

($*$) The set of $t \in [0,1]$ with $\partial X \pitchfork F_t$ has full measure in $[0,1]$.

Now we consider the map



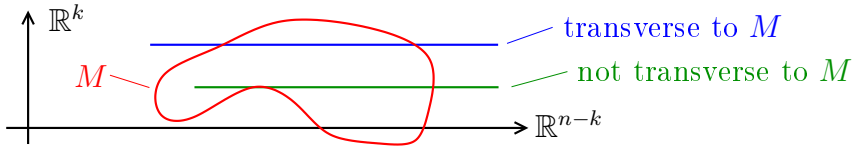
$$\begin{aligned} G\colon Y \times [0,1] &\to M \\ (y,t) &\mapsto \begin{cases} f(y), & \text{if } y \notin [0,\epsilon] \times \partial Y, \\ (\underbrace{F(\widetilde{y}, \tau(s))}_{\in \partial M}, \underbrace{\eta(f(y))}_{\in [0,1]}), & \text{if } y = (s,\widetilde{y}) \in [0,\epsilon] \times \partial Y. \end{cases} \end{aligned}$$

First note that by design the map $G\colon Y \times [0,1] \to M$ is smooth on the open subsets $(Y \setminus [0, \frac{\epsilon}{2}]) \times [0,1]$ and $([0,1) \times \partial Y) \times [0,1]$. It follows from the Smooth Pasting Proposition 19.23

[417] In many situations this claim can also be proved fairly easily using the Homotopic-to-Product-Near-Boundary Lemma 28.6 and Lemma 42.10 applied to ∂Y. But for the most general statements we have to get our hands dirty again.

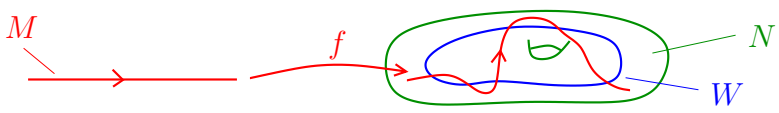
that G is smooth. Note that this is a smooth homotopy with $G_0 = f$. Furthermore for each $t \in [0,1]$ we have $G_t^{-1}(\partial M) = \partial Y$. Next note that G is constant outside of $[0,\epsilon] \times Y$. Furthermore it is constant on $[0,\epsilon] \times \overline{V}$. By the choice of ϵ this means that G is constant on C. In other words, the above is the desired smooth homotopy.

If f is a smooth embedding then we can arrange, using $(*)$ and the Deform Smooth Embedding Proposition 33.6 (2), by rescaling the original map G that G is actually a smooth isotopy. ⊞



It follows from the claim and the Smooth Isotopy Transitivity Proposition 33.3 that it remains to consider the case that $f\colon Y \to M$ is a smooth map with $f^{-1}(\partial M) = \partial Y$ such that $X \pitchfork f$ on $C \cup \partial Y$, where C is a closed subset of Y. But this case we have dealt with in Lemma 42.10. ■

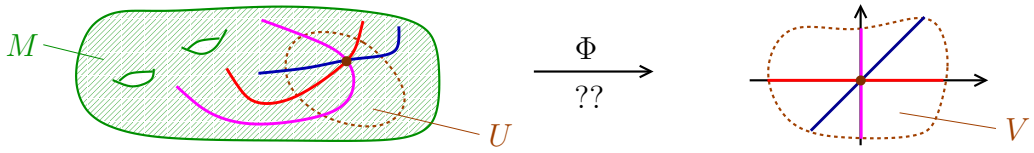
Exercises for Chapter 42.



Exercise 42.1. Let $M \subset \mathbb{R}^n$ be a smooth submanifold. Show that the set

$$\{P \in \mathbb{R}^k \mid M \text{ is not transverse to the submanifold } \mathbb{R}^{n-k} \times \{P\}\}$$

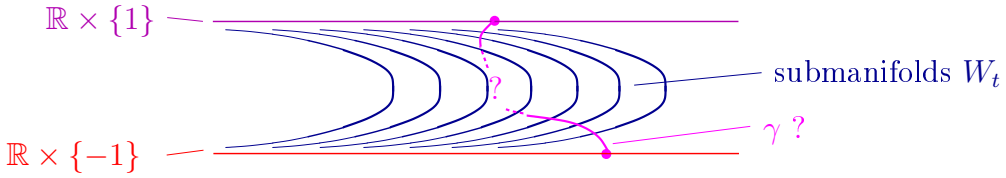
has measure zero in $\mathbb{R}^k$.



Exercise 42.2. Let M and N be two smooth manifolds with empty boundary. We suppose that $\dim(M) < \dim(N)$. Furthermore let W be a submanifold of N without boundary. Finally we suppose that for every point $P \in M$ with $f(P) \in W$ we have the equality $\mathrm{D}f_P(\mathrm{T}_P M) + \mathrm{T}_{f(P)}W = \mathrm{T}_{f(P)}N$. Show that $W \setminus f(M)$ has full measure in W.
Hint. Use the Local Smooth Embedding Theorem 24.8, the Submanifold Transversal Intersection Theorem 42.1 (2) and the Measure-Zero Properties Proposition 30.2.

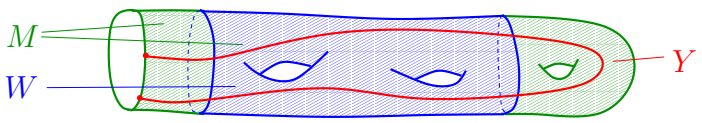
Exercise 42.3. Let M be an oriented smooth manifold and let X and Y be two proper smooth submanifolds that intersect transversally. By the Submanifold Transversal Intersection Theorem 42.1 we obtain oriented submanifolds $X \cap Y$ and $Y \cap X$. What is the relationship between the orientations of $X \cap Y$ and $Y \cap X$?
Remark. This exercise is just a reminder for the reader to do Exercise 25.2.

Exercise 42.4. Let M be a 2-dimensional smooth manifold with $\partial M = \varnothing$, let A, B, C be three 1-dimensional smooth submanifolds of M and let $P \in A \cap B \cap C$ be a point such that all pairs among A, B and C intersect transversally. Does there exist a chart $\Phi\colon U \to V$ for $P \in M$ with $\Phi(P) = (0,0)$, $\Phi(A) \subset \mathbb{R} \times \{0\}$, $\Phi(B) \subset \{0\} \times \mathbb{R}$ and with $\Phi(C) \subset \{(x,x) \in \mathbb{R}^2 \,|\, x \in \mathbb{R}\}$?



Exercise 42.5. Let $L \subset S^1 \times S^2$ be a 1-dimensional smooth submanifold. Show that L is smoothly isotopic to a 1-dimensional smooth submanifold that is contained in $S^1 \times S^2_{\geq 0}$.

Exercise 42.6. We consider the smooth manifold $M = \mathbb{R} \times [-1,1]$ together with the submanifolds



$$W_t \;:=\; \{(t + \tfrac{1}{y^2-1}, y) \,|\, y \in (-1,1)\} \qquad \text{where } t \in \mathbb{R}.$$

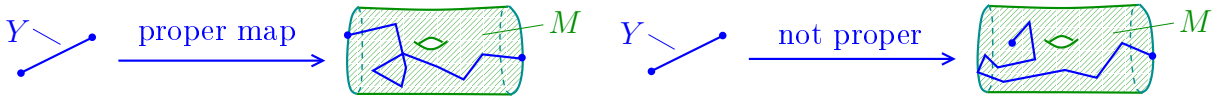
Show that there is no smooth path $\gamma\colon [-1,1] \to M$ that connects the bottom $\mathbb{R} \times \{-1\}$ with the top $\mathbb{R} \times \{1\}$ such that γ is transverse to every W_t, i.e. such that for any $s \in (-1,1)$ with $\gamma(s) \in W_t$ we have $\gamma'(s) \notin V_{\gamma(s)} W_t$.
Remark. This decomposition of the interior of $M = \mathbb{R} \times [-1,1]$ into submanifolds is sometimes called a *Reeb foliation*.

Exercise 42.7. Let M be a closed smooth manifold and let $\alpha\colon S^k \to M$ be a map. Show that there exists an $r \in \mathbb{N}_0$ and a smooth embedding $\varphi\colon S^k \to \partial(M \times \overline{B}^r)$ such that the maps $S^k \xrightarrow{\alpha} M \xrightarrow{x \mapsto (x,0)} M \times \overline{B}^r$ and $\varphi\colon S^k \to M \times \overline{B}^r$ are homotopic.

Exercise 42.8. Let M be an m-dimensional smooth manifold, let W be compact codimension-zero submanifold of M and let Y be a proper submanifold of M that intersects ∂W transversally. Show that $Y \cap W$ is a proper submanifold of W.

Exercise 42.9. Let M be an n-dimensional smooth manifold with $\partial M = \varnothing$ and let X and Y be proper submanifolds of M of dimensions k and l. We assume that there exists an $m \in \mathbb{N}_0$ such that for any $P \in X \cap Y$ we have $\dim(\mathrm{T}_P X + \mathrm{T}_P Y) = m$. Show that $X \cap Y$ is a proper submanifold of M of dimension $k + l - m$.
Hint. Given any $P \in M$ you can assume, after applying a chart, that you are working in an open subset of $\mathbb{R}^n$. Apply the Submanifold Transversal Intersection Theorem 42.1 to a suitable setting.

Project 42.1. Formulate and prove a version of the Submanifold Transversal Intersection Theorem 42.1 for three, or more generally $n \in \mathbb{N}$, submanifolds.



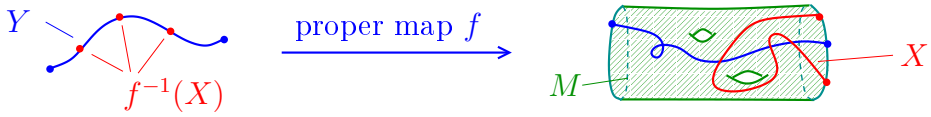
43. The algebraic intersection number

In this section we will use the results from the last chapter to introduce the algebraic intersection number between transverse submanifolds of complementary dimension. The algebraic intersection number is one of the most popular notions of geometric topology. In this chapter we will use this concept to prove the Generalized Smooth Jordan-Brouwer Separation Theorem 43.10 which implies, as we will see in Corollary 43.13, that there is no smooth embedding of $\mathbb{R}\mathrm{P}^2$ or the Klein bottle into $\mathbb{R}^3$.

43.1. The Algebraic intersection number between a submanifold and a map.

We start out with the following definition, which is a special case of the definition on page 650.

Definition. Let M be a topological manifold and let Y be a compact topological manifold. We say that a map $f\colon Y \to M$ is proper if $f^{-1}(\partial M) = \partial Y$.[418]



Definition. Let M be an m-dimensional smooth manifold and let $X \subset M$ be a compact proper submanifold of dimension k.

(1) Let Y be a compact smooth manifold of dimension $m-k$ and let $f\colon Y \to M$ be a proper smooth map that intersects X transversally in the sense of the definition on page 971, i.e. such that $X \pitchfork f$. By the Transversal Preimage Theorem 42.3 we know that $f^{-1}(X)$ is a compact 0-dimensional manifold. As we remarked on page 514 this means that $f^{-1}(X)$ is a finite set. Thus we can define

$$\text{geometric intersection number of } X \text{ and } f \;:=\; \#f^{-1}(X).$$

(2) If Y is a compact proper $(m-k)$-dimensional submanifold of M with $X \pitchfork Y$, then we define

$$\text{geometric intersection number of } X \text{ and } Y \;:=\; \#(X \cap Y).$$

The geometric intersection number (except perhaps for its parity) is frankly not a very interesting number. In the presence of orientations we can introduce a significantly more interesting number.

Definition. Let M be an oriented m-dimensional smooth manifold and let $X \subset M$ be a compact oriented proper submanifold of dimension k.

(1) Let Y be a compact oriented smooth manifold of dimension $m-k$ and let $f\colon Y \to M$ be a proper smooth map with $X \pitchfork f$. By the Transversal Preimage Theorem 42.3 we know that $f^{-1}(X)$ is a compact *oriented* 0-dimensional submanifold. Thus we

[418] It follows from the Compact Image Lemma 2.13 that for a compact topological manifold this definition is equivalent to the definition on page 650.

can define

$$\text{algebraic intersection number of } X \text{ and } f \;:=\; X \cdot f \;:=\; \sum_{P \in f^{-1}(X)} \underbrace{\text{orientation of } P}_{\in\{-1,1\}}.$$

(2) If Y is a compact proper $(m-k)$-dimensional submanifold of M with $X \pitchfork Y$, then we define[419]

$$\text{algebraic intersection number of } X \text{ and } Y \;:=\; X \cdot Y \;:=\; \sum_{P \in X \cap Y} \underbrace{\text{orientation of } P}_{\in\{-1,1\}}.$$

Example. Let M and Y be compact oriented smooth manifolds of the same dimension and let $f\colon Y \to M$ be a smooth map with $f^{-1}(\partial M) \subset \partial Y$. By Sard's Theorem 31.1 there exists a regular value $P \in M \setminus \partial M$. Basically by definition the fact that P is regular means that the map $f\colon Y \to M$ is transverse to the 0-dimensional submanifold $\{P\}$. As usual we give $\{P\}$ the orientation given by $+1$. If one goes through the definitions one sees that

$$\{P\} \cdot f \;=\; \deg(f\colon Y \to M),$$

where $\deg(f\colon Y \to M)$ denotes the degree that we introduced on pages 899 and 925.

The above definition of the algebraic intersection number is very elegant, but it is arguably not very intuitive. Therefore we now give an alternative description of the algebraic intersection number.

Definition. Let M be an oriented m-dimensional smooth manifold and let $X \subset M$ be a compact oriented proper submanifold of dimension $k \in \{1, \dots, m-1\}$.

(1) Let Y be a compact oriented smooth manifold of dimension $m-k$ and let $f\colon Y \to M$ be a proper smooth map with $X \pitchfork f$. Let $P \in f^{-1}(X)$. We set $\operatorname{sign}(P) := 1$, if

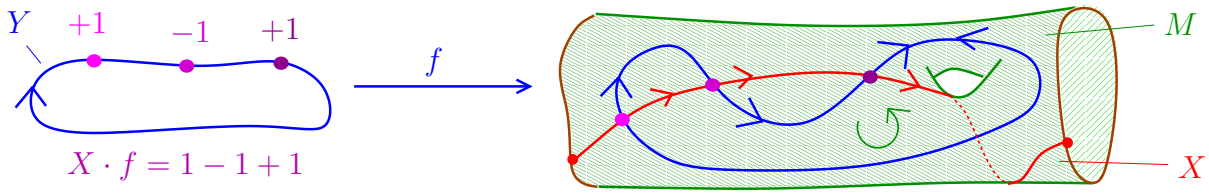
$$(\text{positive basis of } \mathrm{T}_{f(P)}X, \mathrm{D}f_P(\text{positive basis of } \mathrm{T}_P Y)) \;=\; \text{positive basis of } \mathrm{T}_{f(P)}M.$$

Otherwise we set $\operatorname{sign}(P) := -1$.[420]

(2) If Y is a compact oriented proper submanifold of M of dimension $m-k$, then for any $P \in X \cap Y$ we define $\operatorname{sign}(P)$ as in (1).

Lemma 43.1. We suppose that we are in the setting of the above definition. We have

$$X \cdot f \;=\; \sum_{P \in f^{-1}(X)} \operatorname{sign}(P).$$



In particular, if Y is a compact proper submanifold of M with $X \pitchfork Y$, then

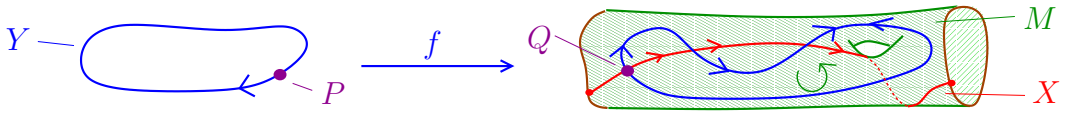
$$X \cdot Y \;=\; \sum_{P \in X \cap Y} \operatorname{sign}(P).$$

Proof. The lemma follows almost immediately from the definitions. But, for peace of mind, let us provide at least some details, to make sure that the sign conventions really do work out. It suffices to show the following claim.

[419] If $\iota\colon Y \to M$ denotes the inclusion map, then it follows immediately from the remark on page 674 that $X \cdot Y = X \cdot \iota$.

[420] It is a straightforward exercise in linear algebra to show that the definition of $\operatorname{sign}(P)$ does not depend on the choice of the positive bases of $\mathrm{T}_P X$ and $\mathrm{T}_P Y$.

geometric intersection number of X and f $= 3$
algebraic intersection number of X and f $= 1$

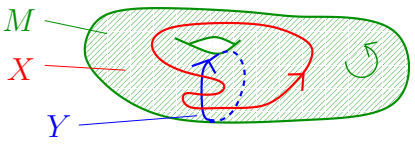


Claim. For each $P \in f^{-1}(X)$ the preimage orientation on P equals $\operatorname{sign}(P)$.

Proof. Let $P \in f^{-1}(X)$. We write $Q = f(P)$. Note that by the Transversal Preimage Theorem 42.3 (2) we have $(\mathrm{D}f_P)^{-1}(\mathrm{T}_Q X) = \mathrm{T}_P\{P\}$. Using this observation, we consider, as in the definition of the preimage orientation on page 673, the following diagram:

$$\begin{array}{ccccc} \mathrm{T}_Q X & \hookrightarrow & \mathrm{T}_Q M & \twoheadrightarrow & \mathrm{T}_Q M/\mathrm{T}_Q X \\ & \nearrow^{\mathrm{D}f_P}_{\cong} & & & \cong\uparrow{\scriptstyle [v]\mapsto[\mathrm{D}f_P(v)]} \\ \mathrm{T}_P\{P\} & \hookrightarrow & \mathrm{T}_P Y & \xrightarrow[\cong]{} & \mathrm{T}_P Y/\mathrm{T}_P\{P\}. \end{array}$$

The diagonal map exists since $\mathrm{T}_P\{P\}$ is 0-dimensional. We equip $\mathrm{T}_Q M/\mathrm{T}_Q X$ with the orientation given by the orientation on $\mathrm{T}_P Y$ and the isomorphism $\mathrm{D}f_P$. It follows immediately from this diagram that the following three statements are equivalent:



(1) The preimage orientation of $P \in f^{-1}(X)$ equals $+1$.
(2) The orientations on $\mathrm{T}_Q X, \mathrm{T}_Q M$ and $\mathrm{T}_Q M/\mathrm{T}_Q X$ are compatible in the sense of the definition on page 671.
(3) $\operatorname{sign}(P) = 1$. ∎

If we are given two oriented submanifolds X and Y of M, then of course it makes sense to consider $X \cdot Y$ as well as $Y \cdot X$. The following lemma elucidates the relationship between these algebraic intersection numbers.[421]

Lemma 43.2. Let M be an oriented smooth manifold and let $X, Y \subset M$ be compact oriented proper submanifolds of M with $\dim(X) + \dim(Y) = \dim(M)$. If $X \pitchfork Y$, then also $Y \pitchfork X$ and

$$Y \cdot X \;=\; (-1)^{\dim(X)\cdot\dim(Y)} \;\cdot\; X \cdot Y.$$

$$\begin{aligned} X \cdot Y &= +1 - 1 + 1 = +1 \\ Y \cdot X &= -1 + 1 - 1 = -1 \end{aligned}$$

Proof. We set $k = \dim(X)$, $l = \dim(Y)$ and $m = \dim(M)$. The cases $k = 0$ and $l = 0$ follow easily from the definitions. Thus let us now suppose that $k, l \in \{1, \dots, m-1\}$. In this

[421] The next lemma deals with a special case of Exercise 42.3.

case it follows from the claim in the proof of Lemma 43.1 that at each $P \in X \cap Y = Y \cap X$ the orientations differ by the sign of the determinant of the following matrix:

$$\begin{pmatrix} 0_{l\times k} & \mathrm{id}_l \\ \mathrm{id}_k & 0_{k\times l} \end{pmatrix}.$$

We leave it to the reader to bring out their favorite tricks for computing determinants to show that the determinant of this matrix equals $(-1)^{k\cdot l}$. ■

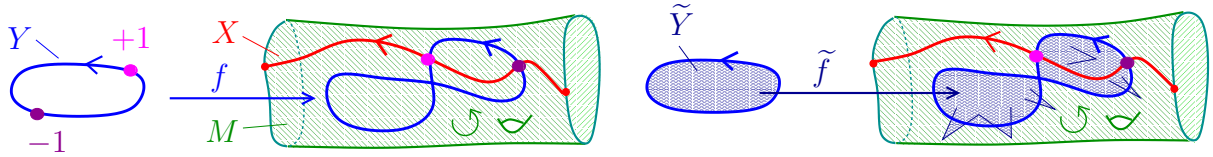
The following elementary lemma shows how the algebraic intersection number is affected by several basic operations.

Lemma 43.3. Let M be an oriented m-dimensional smooth manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k, let Y be a compact oriented smooth manifold of dimension $m-k$ and let $f\colon Y \to M$ be a proper smooth map with $X \pitchfork f$.

(1) As usual we denote by $-X$ the submanifold with the opposite orientation. We have

$$(-X)\cdot f \;=\; -X\cdot f.$$

(2) Let $\widetilde{M}$ be an oriented smooth manifold with $\dim(\widetilde{M}) = \dim(M)$. If $\Phi\colon M \to \widetilde{M}$ is a smooth embedding, then



$$\Phi(X)\cdot(\Phi\circ f) \;=\; \begin{cases} X\cdot f, & \text{if } \Phi \text{ is orientation-preserving} \\ -X\cdot f, & \text{if } \Phi \text{ is orientation-reversing.} \end{cases}$$

(3) Let $\widetilde{Y}$ be an oriented smooth manifold. If $\Psi\colon \widetilde{Y} \to Y$ is a diffeomorphism, then

$$X\cdot(f\circ\Psi) \;=\; \begin{cases} X\cdot f, & \text{if } \Psi \text{ is orientation-preserving} \\ -X\cdot f, & \text{if } \Psi \text{ is orientation-reversing.} \end{cases}$$

Proof. All statements follow easily from the definitions together with the Compatible Orientations Lemma 25.5 (2). ■

Proposition 43.4. (Intersection-Number Zero-if-Extends Proposition) Let M be an oriented m-dimensional smooth manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k, let Y be a *closed* oriented smooth manifold of dimension $m-k$ and let $f\colon Y \to M$ be a proper[422] smooth map with $X \pitchfork f$. If there exists a compact oriented smooth manifold $\widetilde{Y}$ with[423] $\partial\widetilde{Y} = Y$ and if there exists a map[424] $\widetilde{f}\colon \widetilde{Y} \to M$ with $\widetilde{f}|_{\partial\widetilde{Y}} = f$, then $X\cdot f = 0$.

Remark. The Intersection-Number Zero-if-Extends Proposition 43.4 gives in particular a solution to Exercise 38.11.

[422] Since Y is closed this just means that $f(Y) \subset M \setminus \partial M$.

[423] On page 689 we introduced the natural orientation of the boundary of an oriented smooth manifold. With this definition the equality $\partial\widetilde{Y} = Y$ is supposed to be an equality of oriented smooth manifolds.

[424] Note that we do not assume that $\widetilde{f}$ is smooth.

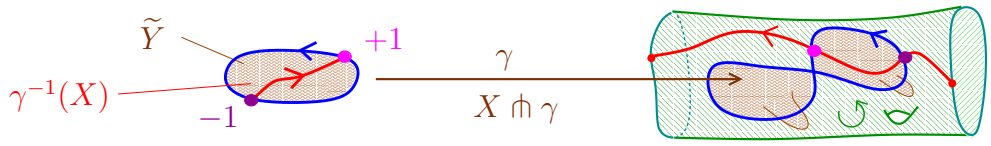
Proof. Let $\widetilde{Y}$ be a compact oriented smooth manifold of dimension $m-k+1$ with $\partial\widetilde{Y} = Y$ and let $\widetilde{f}\colon \widetilde{Y} \to M$ be a map with $\widetilde{f}|_{\partial\widetilde{Y}} = f$. We need to show that $X \cdot f = 0$.

Claim. There exists a smooth map $\gamma\colon \widetilde{Y} \to M \setminus \partial M$ with $\gamma|_{\partial\widetilde{Y}} = f$ such that $X \pitchfork \gamma$.

Proof. We will perform three upgrades to $\widetilde{f}$ to get the desired map.

(α) Since $\widetilde{f}|_{\partial\widetilde{Y}} = f$ is smooth we obtain from the Smooth-on-Boundary-Submanifold Lemma 29.4 together with the Whitney Approximation Theorem 29.1[425] that we can replace $\widetilde{f}$ by a *smooth* map $\alpha\colon \widetilde{Y} \to M$ with $\alpha|_{\partial\widetilde{Y}} = f$.

(β) By hypothesis the map $f\colon Y \to M$ is proper, which in this setting just means that $f(Y) = \alpha(Y) \subset M \setminus \partial M$. It follows from the Push-Away-from-Boundary Corollary 28.5 that we can replace α by a smooth map $\beta\colon \widetilde{Y} \to M \setminus \partial M$ with $\beta|_{\partial\widetilde{Y}} = \alpha|_{\partial\widetilde{Y}} = f$.



(γ) It follows from $X \pitchfork f$ that $X \pitchfork \beta$ on $Y = \partial\widetilde{Y}$. Since β takes values in $M \setminus \partial M$ we can apply the Transversality Theorem 42.5 to the map $\beta\colon \widetilde{Y} \to M \setminus \partial M$ and the closed subset $C := Y = \partial\widetilde{Y}$ of $\widetilde{Y}$. We obtain a smooth map $\gamma\colon \widetilde{Y} \to M \setminus \partial M$ with $\gamma|_{\partial\widetilde{Y}} = \widetilde{f}$ and with $X \pitchfork \gamma$. ⊞

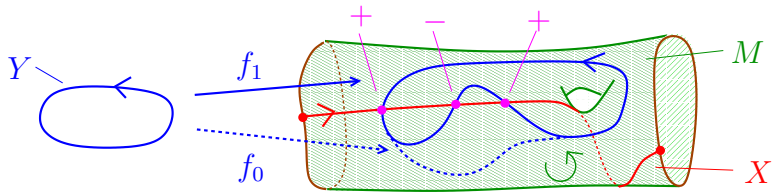
Given a compact oriented 0-dimensional smooth manifold A we denote by $\epsilon(A) \in \mathbb{Z}$ the sum of the orientations of the points in M. We now see that

$$X \cdot f \underset{\uparrow}{=} \epsilon(f^{-1}(X)) \underset{\uparrow}{=} \epsilon(\partial\gamma^{-1}(X)) \underset{\uparrow}{=} \epsilon\Big(\begin{smallmatrix}\text{compact oriented 1-dimensional}\\ \text{smooth manifold}\end{smallmatrix}\Big) \underset{\uparrow}{=} 0.$$

by definition — by the Transversal Preimage Theorem 42.3 (3) and (4), here we use that $X \pitchfork \gamma$, that $\gamma|_{\partial\widetilde{Y}} = f$ and that $\widetilde{Y}$ is compact — Boundary-of-Compact 1-Dimensional Smooth Manifold Proposition 25.18

We have thus proved that $X \cdot f = 0$. ■

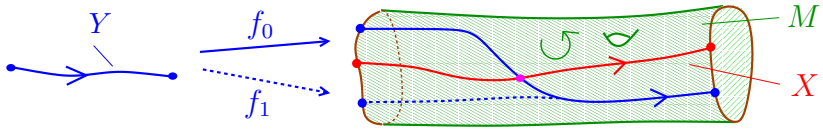
43.2. **The Intersection Number Homotopy Invariance Theorem.** The following theorem can be viewed as an analogue of the Degree Homotopy Invariance Theorem 38.3.



Theorem 43.5. (Intersection Number Homotopy Invariance Theorem) Let M be an oriented m-dimensional smooth manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k, let Y be a *closed* oriented smooth manifold of dimension $m-k$ and let $f_0, f_1\colon Y \to M$ be proper smooth maps with $X \pitchfork f_0$ and $X \pitchfork f_1$. If there exists a homotopy[426] $F\colon Y \times [0,1] \to M$ between f_0 and f_1, then

$$X \cdot f_0 \;=\; X \cdot f_1.$$

Example. Note that in the statement of the Intersection Number Homotopy Invariance Theorem 43.5 we cannot just drop the hypothesis that Y is closed. More precisely, in the



[425] Note that the hypothesis that $f\colon Y \to M$ is proper implies that $f(\partial\widetilde{Y}) \subset M \setminus \partial M$, so we can indeed apply the Whitney Approximation Theorem 29.1.

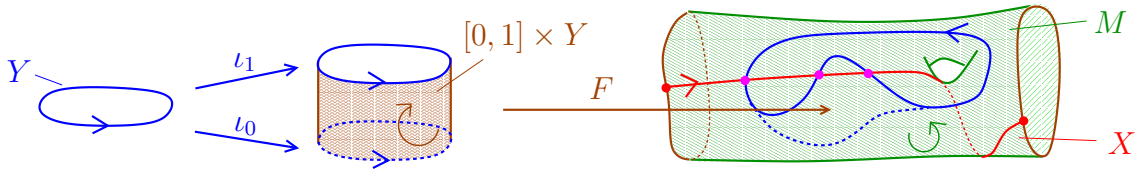
[426] Note that we do not demand that the homotopy is proper or smooth.

$$X \cdot f_1 = -1+1-1 = +1$$
$$X \cdot f_0 = +1$$

figure below we show a smooth manifold M, a proper submanifold X with $\partial X \neq \varnothing$ and two properly smoothly homotopic maps $Y \to M$ with $\partial Y \neq \varnothing$, which are both transverse to X, such that $X \cdot f_0 \neq X \cdot f_1$. As always in mathematics, under extra hypotheses one can in fact allow Y to have non-empty boundary. We will see one such instance with the Intersection Number Homotopy Invariance Theorem II 43.6 and we will see more examples in Chapter 126.

$$X \cdot f_0 = -1$$
$$X \cdot f_1 = 0$$

Proof. Let M be an oriented m-dimensional smooth manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k, let Y be a closed oriented smooth manifold of dimension $m-k$ and let $f_0, f_1 \colon Y \to M$ be smooth maps with $X \pitchfork f_0$ and $X \pitchfork f_1$ such that there exists a homotopy between f_0 and f_1. We need to show that $X \cdot f_1 - X \cdot f_0 = 0$.



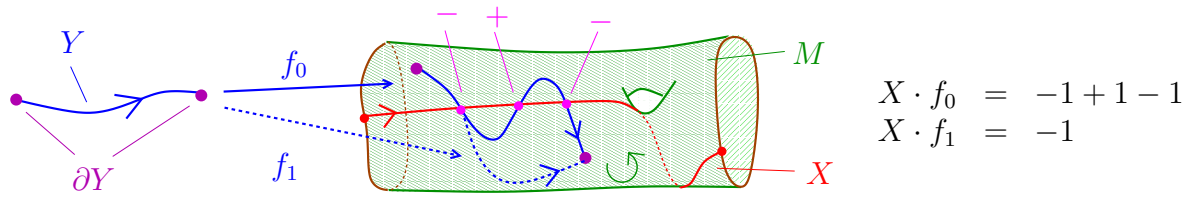
Given $t \in [0,1]$ we equip $\{t\} \times Y$ with the product orientation that we introduced on page 695. Furthermore we denote by

$$\begin{array}{rcl} \iota_t \colon Y & \to & \{t\} \times Y \\ y & \mapsto & (t,y) \end{array}$$

the obvious diffeomorphism. The hypothesis that f_0 and f_1 are homotopic implies that there exists a map $F \colon [0,1] \times Y \to M$ with $F \circ \iota_0 = f_0$ and $F \circ \iota_1 = f_1$. Now we perform the following calculation:

$$X \cdot f_1 - X \cdot f_0 = X \cdot (F \circ \iota_1) - X \cdot (F \circ \iota_0) \overset{\text{by Lemma 43.3 (1) since by the discussion on page 696 we know that } \iota_0 \text{ and } \iota_1 \text{ are orientation-preserving diffeomorphisms}}{=} X \cdot F|_{\{1\}\times Y} - X \cdot F|_{\{0\}\times Y}$$
$$\overset{\text{by Lemma 43.3 (2)}}{=} X \cdot F|_{\{1\}\times Y} + X \cdot F|_{-(\{0\}\times Y)} \overset{\text{since the algebraic intersection number is additive under disjoint unions}}{=} X \cdot F|_{\{1\}\times Y \cup -(\{0\}\times Y)} \overset{\text{see page 696}}{=} X \cdot F|_{\partial([0,1]\times Y)} \overset{\text{Proposition 43.4}}{=} 0.$$

■



Under suitable restrictions one can generalize the Intersection Number Homotopy Invariance Theorem 43.5 from the case of a closed smooth manifold Y to the case of non-empty boundary. In the next section we will make use of the following theorem.

Theorem 43.6. (Intersection Number Homotopy Invariance Theorem II) Let M be an oriented m-dimensional smooth manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k, let Y be a compact oriented smooth manifold of dimension $m-k$ and let $f_0, f_1 \colon Y \to M \setminus \partial M$ be smooth maps with $X \pitchfork f_0$ and $X \pitchfork f_1$. We make the following hypothesis on the behavior of the maps on the boundary:

(1) $f_0|_{\partial Y} = f_1|_{\partial Y}$.
(2) $f_0(\partial Y) \cap X = f_1(\partial Y) \cap X = \varnothing$.

If f_0 and f_1 are homotopic rel ∂Y, then

$$X \cdot f_0 \;=\; X \cdot f_1.$$

Proof. The proof can be found in the long version of the lecture notes. ■

Proof. Once again we need to show that $X \cdot f_1 - X \cdot f_0 = 0$. Since $[0,1] \times Y$ is a smooth manifold *with corner* $\partial Y \times \{0,1\}$ we cannot use the off-the-shelf approach that we took in the proof of the Intersection Number Homotopy Invariance Theorem 43.5. Therefore in the following we also need to look under the hood of the proof of the Intersection-Number Zero-if-Extends Proposition 43.4 to make the argument work.

We will outline the changes that need to be made. As before, given $t \in [0,1]$ we equip $\{t\} \times Y$ with the product orientation and we denote by

$$\begin{array}{rccc} \iota_t \colon & Y & \to & \{t\} \times Y \\ & y & \mapsto & (x,y) \end{array}$$

the obvious diffeomorphism.

Claim 1. There exists a map $\delta \colon [0,1] \times Y \to M$ with the following properties:

(1) We have $\delta \circ \iota_0 = f_0$ and $\delta \circ \iota_1 = f_1$.
(2) For each $t \in [0,1]$ and $P \in \partial Y$ we have $\delta(t,P) = f_0(P)$.
(3) We have $\delta([0,1] \times \partial Y) \cap \partial M = \varnothing$.
(4) The map δ is smooth.

Proof. The proof of the claim uses an approach similar to the one taken in the proof of the Intersection-Number Zero-if-Extends Proposition 43.4. Again we proceed in several steps:

(1) Since f_0 and f_1 are homotopic rel ∂Y there exists a map $\alpha \colon [0,1] \times Y \to M$ which satisfies (1) and (2).
(2) the Push-Away-from-Boundary Corollary 28.5 implies that we can replace α by a map β which now satisfies (1), (2) and (3).
(3) Next note that by the Trivial-Near-The-Ends-Lemma 33.4 we can replace β by a homotopy $\gamma \colon [0,1] \times Y \to M$ which has the following properties:
   (a) For each $t \in [0, \frac{1}{4}]$ we have $\gamma \circ \iota_t = f_0$.

[426] Again we do not demand that the homotopy is smooth.

(b) For each $t \in [\frac{3}{4}, 1]$ we have $\gamma \circ \iota_t = f_1$.

(4) We apply the Whitney Approximation Theorem 29.1 to $\gamma\colon (0,1)\times Y \to M \setminus \partial M$ and the closed subset $A = ((0, \frac{1}{8}]\times Y) \cup ((\frac{7}{8}, 1]\times Y) \cup ([0,1]\times \partial Y)$ to obtain a smooth map $\delta\colon (0,1)\times Y \to M\setminus\partial M$. We extend δ to $[0,1]\times M\setminus\partial M$ via f_0 and f_1. It follows from the obvious extension of the Smooth Pasting Proposition 19.23 to smooth manifolds with corner that this map $\delta\colon [0,1]\times Y \to M\setminus\partial M$ is smooth. By construction it has all the desired properties. ⊞

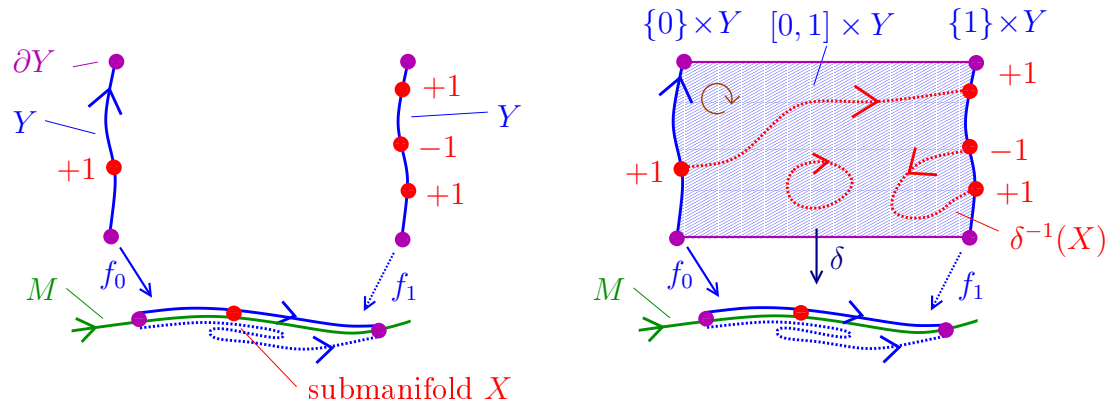
Claim 2. We have $X \cdot \delta_{\partial([0,1]\times Y)} = 0$.

Proof. If $\partial Y = \varnothing$, then this equality follows immediately from the Intersection-Number Zero-if-Extends Proposition 43.4. Now consider the case that $\partial Y \neq \varnothing$. We make the following two observations:

(1) By construction we have $\delta^{-1}(X) \subset M \setminus \partial M$.

(2) Since X is closed and since Y is compact we see that the preimage $\delta^{-1}(X)$ is compact.

Note that it follows from (1) and (2), and the argument of the proof of the Intersection-Number Zero-if-Extends Proposition 43.4, that $\delta^{-1}(X)$ is a compact submanifold of the smooth manifold $[0,1]\times(Y\setminus\partial Y)$. Therefore, by exactly the same argument as in the proof of the Intersection-Number Zero-if-Extends Proposition 43.4 we see that $X \cdot \delta_{\partial([0,1]\times Y)} = 0$. ⊞



Now we perform the following calculation:

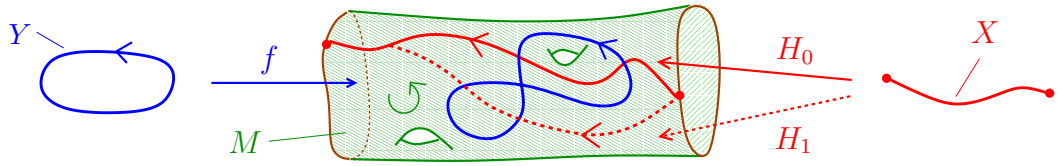
$$X\cdot f_1 - X\cdot f_0 \;=\; X\cdot(\delta\circ\iota_1) - X\cdot(\delta\circ\iota_0) \;\underset{\uparrow}{=}\; X\cdot\delta|_{\{1\}\times Y} - X\cdot\delta|_{\{0\}\times Y}$$

by Lemma 43.3 (1) since by the discussion on page 696 we know that ι_0 and ι_1 are orientation-preserving diffeomorphisms

$$\underset{\uparrow}{=} X\cdot\delta|_{\{1\}\times Y} + X\cdot\delta|_{-(\{0\}\times Y)} \underset{\uparrow}{=} X\cdot\delta|_{\{1\}\times Y \cup -(\{0\}\times Y)} \underset{\uparrow}{=} X\cdot\delta|_{\partial([0,1]\times Y)} \underset{\uparrow}{=} 0.$$

by Lemma 43.3 (2); since the algebraic intersection number is additive under disjoint unions; see page 696; Claim 2 ■

In the Intersection Number Homotopy Invariance Theorem 43.5 we showed that under suitable hypotheses the algebraic intersection number $X \cdot f$ stays constant if we "deform" f. The question arises, what happens if we "deform" the submanifold X by a smooth isotopy. If we are dealing with the algebraic intersection number between two submanifolds, then we



[426] Note that $[0,1]\times Y$ could be a smooth manifold with non-empty corner, but $(0,1)\times Y$ is fortunately smooth manifold without corner. This is the reason why we want to work with $(0,1)\times Y$.

can use the (anti-) symmetry from Lemma 43.2 to swap the roles of the two inputs and we can reduce the problem to the Intersection Number Homotopy Invariance Theorem 43.5.

In the general setting we have the following theorem:

Proposition 43.7. (Intersection Number Homotopy Invariance Theorem III) Let M be an oriented m-dimensional smooth manifold, let Y be a closed oriented smooth manifold of dimension $m-k$, let X be a compact oriented smooth manifold of dimension k and let $H\colon X\times[0,1]\to M$ be a proper smooth isotopy such that[427] $H_0(X)\pitchfork f$ and $H_1(X)\pitchfork f$. Then

$$H_0(X)\cdot f \;=\; H_1(X)\cdot f.$$

Proof. The natural idea would be to try to modify the argument of the Intersection Number Homotopy Invariance Theorem 43.5. We will do it differently though, namely we will employ the Isotopy Extension Theorem 36.1, to sidestep all difficulties.

By the Isotopy Extension Theorem 36.1 there exists a diffeotopy $\Phi\colon M\times[0,1]\to M$ with the following properties:

(1) $\Phi_0=\mathrm{id}$.
(2) $\Phi_1\circ H_0=H_1\colon X\to M$.

We now see that

$$H_0(X)\cdot f \;\underset{\uparrow}{=}\; \Phi_1(H_0(X))\cdot(\Phi_1\circ f) \;=\; H_1(X)\cdot(\Phi_1\circ f) \;\underset{\uparrow}{=}\; H_1(X)\cdot f.$$

since $\Phi_0=\mathrm{id}$ we know by the Smooth Isotopy-Orientation Proposition 34.2 that Φ_1 is an orientation-preserving diffeomorphism, the statement now follows from Lemma 43.3

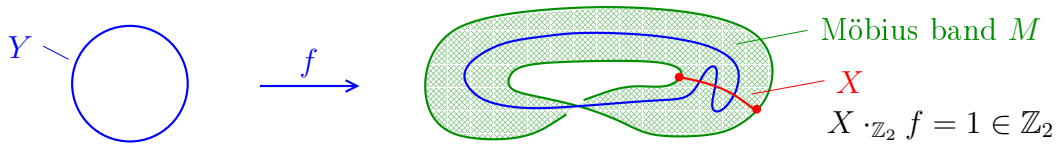
by the Intersection Number Homotopy Invariance Theorem 43.5, since $(x,t)\mapsto\Phi_t\circ f$ is a homotopy between $f=\mathrm{id}\circ f=\Phi_0\circ f$ and $\Phi_1\circ f$

■

43.3. **The $\mathbb{Z}_2$-algebraic intersection number.** If we do not have orientations at hand, then we cannot define the $\mathbb{Z}$-valued algebraic intersection number. We can of course still consider the geometric intersection number, but the geometric intersection number is clearly not invariant under homotopies. But, playing around with pictures shows that the parity of the geometric intersection number has a chance of being invariant under homotopies. This hope leads us to the following definition.

Definition. Let M be an m-dimensional smooth manifold and let $X\subset M$ be a compact proper submanifold of dimension k.

(1) Let Y be a compact smooth manifold of dimension $m-k$ and let $f\colon Y\to M$ be a proper smooth map with $X\pitchfork f$. We define the



$$\mathbb{Z}_2\text{-valued intersection number of } X \text{ and } f \;:=\; X\cdot_{\mathbb{Z}_2} f \;:=\; [\#f^{-1}(X)]\in\mathbb{Z}_2.$$

[427] Note that it follows from the Smooth Embedding Theorem 24.10 that each $H_t(X)$ is indeed a proper smooth submanifold of M.

(2) If Y is a compact proper $(m-k)$-dimensional submanifold of M with $X \pitchfork Y$, then we define

$$\mathbb{Z}_2\text{-valued intersection number of } X \text{ and } Y \;:=\; X \cdot_{\mathbb{Z}_2} Y \;:=\; [\#(X \cap Y)] \in \mathbb{Z}_2.$$

Remark. In the setting of the above definition, if X, Y and M are actually oriented, then we evidently have $X \cdot_{\mathbb{Z}_2} f = X \cdot f \mod 2$.

Our previous results on the algebraic intersection numbers in the oriented setting also have obvious analogues in the unoriented "mod 2"-setting. We just need to delete the adjective "oriented" and replace $\mathbb{Z}$ by $\mathbb{Z}_2$. For example we have the following analogue the Intersection-Number Zero-if-Extends Proposition 43.4.

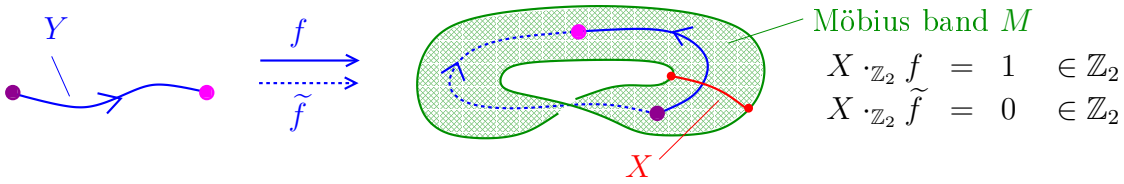
Proposition 43.8. (Intersection-Number Zero-if-Extends Proposition) Let M be an m-dimensional smooth manifold, let $X \subset M$ be a compact proper submanifold of dimension k, let Y be a closed smooth manifold of dimension $m-k$ and let $f\colon Y \to M$ be a proper smooth map with $X \pitchfork f$. If there exists a compact smooth manifold $\widetilde{Y}$ with $\partial\widetilde{Y} = Y$ and a map $\widetilde{f}\colon \widetilde{Y} \to M$ with $\widetilde{f}|_{\partial\widetilde{Y}} = f$, then $X \cdot_{\mathbb{Z}_2} f = 0$.

Proof. The proof is almost identical to the proof of the Intersection-Number Zero-if-Extends Proposition 43.4. ■

At the end of the day, the only result about $\mathbb{Z}_2$-value intersection numbers we really care about is the following analogue of the Intersection Number Homotopy Invariance Theorem 43.6. In fact we will put it to good use in the next section in our proof of the Generalized Smooth Jordan-Brouwer Separation Theorem 43.10.

Theorem 43.9. (Intersection Number Homotopy Invariance Theorem) Let M be an m-dimensional smooth manifold, let $X \subset M$ be a compact proper submanifold of dimension k and let Y be compact oriented smooth manifold of dimension $m-k$. Furthermore let $f_0, f_1\colon Y \to M \setminus \partial M$ be smooth maps with $X \pitchfork f_0$ and $X \pitchfork f_1$. We make the following hypotheses on the behavior of the maps on the boundary:

(1) $f_0|_{\partial Y} = f_1|_{\partial Y}$.
(2) $f_0(\partial Y) \cap X = f_1(\partial Y) \cap X = \varnothing$.



If f_0 and f_1 are homotopic rel ∂Y, then

$$X \cdot_{\mathbb{Z}_2} f_0 \;=\; X \cdot_{\mathbb{Z}_2} f_1.$$

Proof. Again the proof is a worry-free analogue of the proof of the original Intersection Number Homotopy Invariance Theorem 43.6. Along the way we just need to replace the Intersection-Number Zero-if-Extends Proposition 43.4 by the above Intersection-Number Zero-if-Extends Proposition 43.8. ■

Example. Let M be the Möbius band. We consider the proper 1-dimensional submanifold X and the two maps $f, \widetilde{f}\colon [0,1] \to M$ shown in the figure below. Since $X \cdot_{\mathbb{Z}_2} f = 0 \in \mathbb{Z}_2$

and $X \cdot_{\mathbb{Z}_2} \widetilde{f} = 0 \in \mathbb{Z}_2$ we obtain from the Intersection Number Homotopy Invariance Theorem 43.9 that the two maps are not homotopic rel $\{0,1\}$.

43.4. The Smooth Jordan-Brouwer Separation Theorem.

Theorem 43.10. (Generalized Smooth Jordan-Brouwer Separation Theorem) Let M be a connected non-empty smooth codimension-one submanifold of $\mathbb{R}^n$ that is closed if viewed as a smooth manifold in its own right.

(1) The complement $\mathbb{R}^n \setminus M$ has precisely two path-components[428], one of which is bounded and one which is unbounded.
(2) Let A and B be the two path-components of $\mathbb{R}^n \setminus M$. The following statements hold:
  (a) The closures $\overline{A}$ and $\overline{B}$ are codimension-zero submanifolds of $\mathbb{R}^n$.
  (b) $\partial A = \partial \overline{A} = \partial B = \partial \overline{B} = \overline{A} \cap \overline{B} = M$.[429]

As an almost immediate corollary we obtain the following result:

Corollary 43.11. (Smooth Jordan-Brouwer Separation Theorem) Let $n \in \mathbb{N}$.

(1) Let M be a closed connected non-empty n-dimensional smooth manifold. Given any smooth embedding $f\colon M \to \mathbb{R}^{n+1}$ the complement $\mathbb{R}^{n+1} \setminus f(M)$ has precisely two path-components.
(2) If $f\colon S^n \to \mathbb{R}^{n+1}$ is a smooth embedding, then $\mathbb{R}^{n+1} \setminus f(S^n)$ has precisely two path-components.

Proof of Corollary 43.11. The first statement follows from the Smooth Embedding Theorem 24.10 together with the Generalized Smooth Jordan-Brouwer Separation Theorem 43.10. The second statement is evidently an immediate consequence of the first statement. ■

Remark.

(1) The case $n = 1$ is sometimes referred to as the *Smooth Jordan Curve Theorem*.

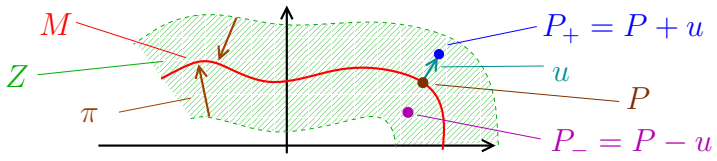
[428] It follows from the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 (2) that $\mathbb{R}^n \setminus M$ is an open subset of $\mathbb{R}^n$. Thus it follows from the Topological Manifolds-Local Properties Lemma 18.8 that the path-components of $\mathbb{R}^n \setminus M$ are also the components of $\mathbb{R}^n \setminus M$.

[429] Since $\overline{A}$ and $\overline{B}$ are closed subsets and since they are codimension-zero submanifolds it follows from the Codimension-Zero Submanifold Proposition 19.38 that the boundaries of $\overline{A}$ and $\overline{B}$ viewed as smooth manifolds agree with the boundaries of $\overline{A}$ and $\overline{B}$ viewed as subsets of $\mathbb{R}^n$.

(2) (a) In the Jordan–Brouwer Separation Theorem 82.2 we will generalize the Smooth Jordan-Brouwer Separation Theorem 43.11 from smooth embeddings $S^n \to \mathbb{R}^{n+1}$ to injective continuous maps $S^n \to \mathbb{R}^{n+1}$.
(b) In the Generalized Jordan–Brouwer Separation Theorem 124.4 we will generalize the Smooth Jordan-Brouwer Separation Theorem 43.11 (1) from smooth embeddings $M \to \mathbb{R}^{n+1}$ of closed connected non-empty smooth manifolds to embeddings $M \to \mathbb{R}^{n+1}$ of closed connected non-empty topological manifolds.

Proof of the Generalized Smooth Jordan-Brouwer Separation Theorem 43.10. Let M be a connected non-empty smooth codimension-one submanifold of $\mathbb{R}^n$ that is closed if viewed as a smooth manifold in its own right. On several occasions we will use that it follows from the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 (2) that M is a closed subset of $\mathbb{R}^n$. The cases $n = 0$ and $n = 1$ are trivial, hence we now assume that $n \geq 2$.

Since M is closed we obtain from the Neighborhood Projection Theorem 28.1 that there exists an $\epsilon > 0$ such that



$$Z := \left\{P + w \,|\, P \in M \text{ and } w \in \left(\widetilde{\mathrm{T}}_P M\right)^\perp \text{ with } \|w\| < \epsilon\right\}$$

is an open neighborhood of $M \subset \mathbb{R}^n$ and such that the map

$$\begin{array}{rcll} \pi\colon Z & \to & M & \\ P + w & \mapsto & P & \text{where } P \in M \text{ and } w \in \left(\widetilde{\mathrm{T}}_P M\right)^\perp \end{array}$$

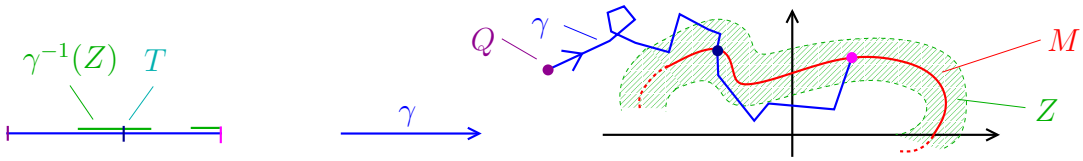
is well-defined. We also saw that the map π is smooth and that π is a retraction $Z \to M$.

Since M is non-empty we can pick a point $P \in M$. Since M has codimension 1 in $\mathbb{R}^n$ there exist precisely two vectors $u \in (\widetilde{\mathrm{T}}_P M)^\perp$ with $\|u\| = \frac{\epsilon}{2}$. Let u be one of the two vectors. We set $P_\pm = P \pm u$.

Claim 0. The topological space $Z \setminus M$ contains at most two path-components.

Proof. Let $Q \in Z \setminus M$. By Lemma 2.30 we know that being connected via a path is an equivalence relation. Thus it suffices to show that there exists a path from Q to P_- or P_+. We pick $z \in M$ and $v \in (\widetilde{\mathrm{T}}_P M)^\perp$ with $\|v\| < \epsilon$ and with $z + v = Q$. Since M is connected there exists a path $\gamma\colon [0,1] \to M$ with $\gamma(0) = z$ and $\gamma(1) = P$. Since M is a codimension-one submanifold one can show easily, either by hand[430] or using the Path-Thickening Proposition 37.1 together with the cross product from page 678, that there is a smooth map $\widetilde{\gamma}\colon [0,1] \to \mathbb{R}^n$ with the following properties:

(a) $\widetilde{\gamma}(0) = \gamma(0) + v$,
(b) for each $t \in [0,1]$ we have $\widetilde{\gamma}(t) - \gamma(t) \in (\widetilde{\mathrm{T}}_{\gamma(t)} M)^\perp$,
(c) for each $t \in [0,1]$ we have $\|\widetilde{\gamma}(t) - \gamma(t)\| = \|v\|$.



[430] The "by hand" approach is the content of Exercise 25.16.

Note that $\widetilde{\gamma}(1) = P + \lambda \cdot u$ for some $\lambda \in (-2, 0) \cup (0, 2)$. It follows that $\widetilde{\gamma}(1)$ is connected via a path in $Z \setminus M$ to $P + \lambda \cdot u$, thus $\widetilde{\gamma}(1)$ is also connected via a path in $Z \setminus M$ to P_- or to P_+. ⊞

Claim 1. The topological space $\mathbb{R}^n \setminus M$ contains at most two path-components.

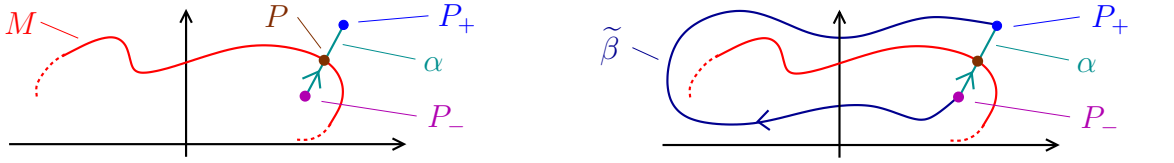
Proof. Let $Q \in \mathbb{R}^n \setminus M$. Since $\mathbb{R}^n$ is path-connected we know that there exists a path $\gamma\colon [0,1] \to \mathbb{R}^n$ with $\gamma(0) = Q$ and $\gamma(1) \in M$. Since M is a closed subset of $\mathbb{R}^n$ we know that $\gamma^{-1}(M) \subset [0,1]$ is a closed subset of the compact space $[0,1]$. It follows from the Compact-Closed Lemma 1.21 that $\gamma^{-1}(M)$ is compact. Since $0 \notin \gamma^{-1}(M)$ we deduce from the Compact Image Lemma 2.13 (2) that $\gamma^{-1}(M)$ has a minimal element, i.e. there exists a $T \in \gamma^{-1}(M)$ such that $[0,T) \cap \gamma^{-1}(M) = \varnothing$. Since Z is an open neighborhood of $M \subset \mathbb{R}^n$ there exists an $\epsilon > 0$ such that $(T-\epsilon, T) \subset \gamma^{-1}(Z)$. Thus the restriction of γ to the interval $[0, T - \frac{\epsilon}{2}]$ gives us a path within $\mathbb{R}^n \setminus M$ from P to a point in $Z \setminus M$. It follows from Claim 0 that $\mathbb{R}^n \setminus M$ has indeed at most two path-components. ⊞

Claim 2.

(1) Let $P \in M$ and let $u \in (\widetilde{\mathrm{T}}_P M)^\perp$ with $\|u\| < \epsilon$. The points $P_\pm = P \pm u$ lie in two different path-components of $\mathbb{R}^n \setminus M$.

(2) The topological space $\mathbb{R}^n \setminus M$ contains at least two path-components.

Proof. Since M is non-empty we see that (2) is an immediate consequence of (1). Therefore it suffices to prove (1). Thus let $P \in M$ and let $u \in (\widetilde{\mathrm{T}}_P u)^\perp$ with $\|u\| < \epsilon$. We set $P_\pm = P \pm u$. We need to show that the points $P_-, P_+ \in \mathbb{R}^n \setminus M$ lie in different path-components of $\mathbb{R}^n \setminus M$. Let $\alpha\colon [0,1] \to \mathbb{R}^n$ the "straight path" from P_- to P_+ that is given by $\alpha(t) = (1-t) \cdot P_- + t \cdot P$. It follows from the properties of Z and the choice of u that the path α from $P_- = P - u$ to $P_+ = P + u$ intersects M precisely at $t = \frac{1}{2}$ and that this intersection point is transverse. Suppose that there exists also a path $\beta\colon [0,1] \to \mathbb{R}^n \setminus M$ from P_- to P_+. Since M is a closed subset of $\mathbb{R}^n$ we know that $\mathbb{R}^n \setminus M$ is an open subset, in particular it is a smooth submanifold of $\mathbb{R}^n$. Thus it follows from the Smooth Path-Connectivity Proposition 19.29 that there exists in fact a smooth path $\widetilde{\beta}\colon [0,1] \to \mathbb{R}^n \setminus M$ from P_- to P_+. Note that



$$\begin{array}{rcl} F\colon [0,1] \times [0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \alpha(t) \cdot (1-s) + \widetilde{\beta}(t) \cdot s \end{array}$$

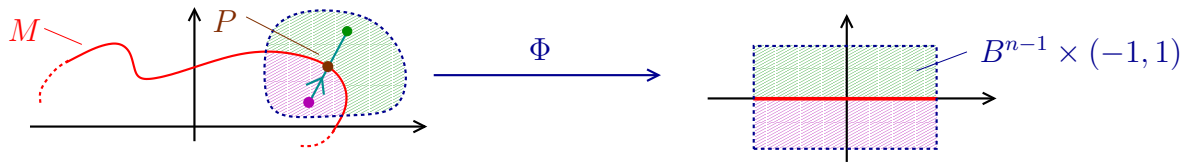
is a homotopy rel $\{0,1\}$ from α to $\widetilde{\beta}$. We obtain the following equality of intersection numbers of submanifolds of $\mathbb{R}^n$:

Intersection Number Homotopy Invariance Theorem 43.9

$$0 \underset{\uparrow}{=} M \cdot_{\mathbb{Z}_2} \widetilde{\beta} \overset{\downarrow}{=} M \cdot_{\mathbb{Z}_2} \alpha \underset{\uparrow}{=} 1 \in \mathbb{Z}_2.$$

since $\widetilde{\beta}$ takes values in $\mathbb{R}^n \setminus M$ since α intersects M transversally precisely in $t = 0$ ⊞

Claims 1 and 2 show that $\mathbb{R}^n \setminus M$ contains precisely two path-components. Since M is compact there exists an $r > 0$ such that $M \subset B_r(0)$. It follows from our hypothesis that $n \geq 2$ and the Complement Connected Lemma 2.29 that $\mathbb{R}^n \setminus B_r^n(0)$ is path-connected. Therefore $\mathbb{R}^n \setminus B_r^n(0)$ is contained in a path-component B of $\mathbb{R}^n \setminus M$. We denote the other path-component of $\mathbb{R}^n \setminus M$ by A. We set $\widetilde{A} := A \cup M$ and we set $\widetilde{B} := B \cup M$. By the Codimension-Zero Submanifold Proposition 19.38 it remains to prove the following claim.



Claim 3.
(1) $\widetilde{A}$ and $\widetilde{B}$ are closed subsets of $\mathbb{R}^n$.
(2) $\widetilde{A}$ is compact.
(3) $\widetilde{A}$ and $\widetilde{B}$ are codimension-zero submanifolds of $\mathbb{R}^n$ with $\partial\widetilde{A} = \partial\widetilde{B} = \widetilde{A} \cap \widetilde{B} = M$.

Proof.

(1) As we remarked above $\mathbb{R}^n \setminus M$ is an open subset of $\mathbb{R}^n$. In particular, as we remarked on page 176, $\mathbb{R}^n \setminus M$ is locally path-connected. It follows from Locally Path-Connected Lemma 2.40 and the Components-are-Closed Lemma 2.34 that A and B are open subsets of $\mathbb{R}^n \setminus M$. Since M is a closed subset of $\mathbb{R}^n$ we see that A and B are both open subsets of $\mathbb{R}^n$. It follows that $\widetilde{A} = \mathbb{R}^n \setminus B$ and $\widetilde{B} = \mathbb{R}^n \setminus A$ are closed.
(2) By design we have $\widetilde{A} \subset B_r^n$. Since $\widetilde{A}$ is closed it follows from the Heine-Borel Theorem 1.24 that $\widetilde{A}$ is in fact compact.
(3) We show that $\widetilde{A}$ is a codimension-zero submanifold of $\mathbb{R}^n$ with $\partial\widetilde{A} = M$. For the points in A the identity defines a submanifold chart. Now let $P \in M$. Since M is a codimension-zero submanifold there exists a chart $\Phi\colon U \to B^{n-1} \times (-1,1)$ around P such that $\Phi(U \cap M) = B^{n-1} \times \{0\}$. Note that $B^{n-1} \times (0,1)$ and $B^{n-1} \times (-1,0)$ are path-connected. Furthermore note that it follows almost immediately from Claim (3a) that $\Phi^{-1}(B^{n-1} \times (0,1))$ and $\Phi^{-1}(B^{n-1} \times (-1,0))$ lie in two different path-components of $\mathbb{R}^n \setminus M$. These two observations imply that either we have $\Phi(U \cap \widetilde{A}) = B^{n-1} \times [0,1)$ or we have $\Phi(U \cap \widetilde{A}) = B^{n-1} \times (-1,0]$. Either way we have found (possibly after composing Φ with a reflection) a submanifold chart of type (γ) for P.

The same argument works for $\widetilde{B}$. We have thus shown the desired statements. ■

Using the Smooth Jordan-Brouwer Separation Theorem 43.11 we can easily prove the following pretty proposition.

Proposition 43.12. (Smooth Codimension-One Orientability Proposition) Let M be some closed n-dimensional smooth manifold. If there exists a smooth embedding $M \to \mathbb{R}^{n+1}$, then M is orientable.

Remark.

(1) On page 2705 we will give an alternative proof of the Smooth Codimension-One Orientability Proposition 43.12.
(2) In the Topological Codimension-One Orientability Proposition 124.5 we will strengthen the result.

Proof. Let M be a closed n-dimensional smooth manifold. that admits a smooth embedding $M \to \mathbb{R}^{n+1}$. It is clear that we only need to deal with the case that M is non-empty and connected. Now let us show that M is orientable. The proof proceeds in three easy steps:

(1) By the Smooth Embedding Theorem 24.10 we know that $f(M)$ is a closed codimension-one smooth submanifold of $\mathbb{R}^{n+1}$ such that $f\colon M \to f(M)$ is a diffeomorphism.
(2) It follows from the Smooth Jordan-Brouwer Separation Theorem 43.11 that there exists a codimension-zero submanifold A of $\mathbb{R}^{n+1}$ such that $\partial A = f(M)$.
(3) By the Basics-of-Orientations Lemma 25.13 we know that A is orientable. It follows from the Boundary Orientation Lemma 25.17 that $\partial A = f(M)$ is orientable. Since f is a diffeomorphism we obtain that M itself is orientable. ■

In Question 24.13 (2) we asked whether $\mathbb{R}\mathrm{P}^2$ or the Klein bottle admit a smooth embedding into $\mathbb{R}^3$. We can now give a negative answer.

Corollary 43.13. Neither $\mathbb{R}\mathrm{P}^2$ nor the Klein bottle admit a smooth embedding into $\mathbb{R}^3$.

Remark. In Corollary 124.6 we will see $\mathbb{R}\mathrm{P}^2$ and the Klein bottle do not even admit a (possibly non-smooth) embedding into $\mathbb{R}^3$.

Proof. By the Surface Non-Orientability Lemma 25.20 we know that $\mathbb{R}\mathrm{P}^2$ and the Klein bottle are both non-orientable. Since both are closed 2-dimensional smooth manifolds it follows from the Smooth Codimension-One Orientability Proposition 43.12 that neither $\mathbb{R}\mathrm{P}^2$ nor the Klein bottle admit a smooth embedding into $\mathbb{R}^3$. ■

Proposition 43.14. If $n \in \mathbb{N}_{\geq 2}$ is even, then there is no smooth embedding from $\mathbb{R}\mathrm{P}^n$ into $\mathbb{R}^{n+1}$.

Proof. Let $n \in \mathbb{N}_{\geq 2}$ be even. It follows from the Real Projective Space Orientability Lemma 25.21 that $\mathbb{R}\mathrm{P}^n$ is non-orientable. Since $\mathbb{R}\mathrm{P}^n$ is a closed n-dimensional smooth manifold it follows from the Smooth Codimension-One Orientability Proposition 43.12 that there is no smooth embedding from $\mathbb{R}\mathrm{P}^n$ into $\mathbb{R}^{n+1}$. ■

Remark. In Proposition 123.11 we will see that the conclusion of Proposition 43.14 holds for any $n \in \mathbb{N}_{\geq 2}$, i.e. regardless of whether or not $\mathbb{R}\mathrm{P}^n$ is orientable, it cannot be smoothly embedded into $\mathbb{R}^{n+1}$.

Exercises for Chapter 43.

Exercise 43.1. Let $f\colon A \to M$ and $g\colon M \to N$ be smooth maps between compact oriented smooth manifolds. Let $Y \subset N$ be a compact oriented proper submanifold such that $Y \pitchfork g$. By the Transversal Preimage Theorem 42.3 we know that $g^{-1}(Y)$ is a compact oriented proper submanifold of M. We suppose that $\dim(A) + \dim(Y) = \dim(M)$ and we suppose that $g^{-1}(Y) \pitchfork f$. Show that

$$X \cdot (g \circ f) \;=\; g^{-1}(X) \cdot f.$$

Exercise 43.2. Let X be a closed oriented smooth manifold, let $f\colon X \to M$ be a smooth map to a compact oriented smooth manifolds and let $Y \subset N$ be a compact oriented proper submanifold with $\dim(X) + \dim(Y) = \dim(M)$. Finally let $\widetilde{X}$ be a closed oriented smooth manifold with $\dim(\widetilde{X}) = \dim(X)$ and let $\varphi\colon \widetilde{X} \to X$ be a smooth map. Show that

$$X \cdot (f \circ \varphi\colon \widetilde{X} \to M) \;=\; (X \cdot (f\colon X \to M)) \;\cdot\; \deg(\varphi\colon \widetilde{X} \to X).$$

Exercise 43.3. In the example on page 993 we saw that the conclusion of Theorem 43.5 does not hold if we do not assume that Y is closed. Go through the proof of Theorem 43.5 and find out where the proof fails if Y is not closed.

Exercise 43.4. Let M be a connected oriented smooth manifold and let X, Y be two closed oriented submanifolds with $\dim(X) = \dim(Y) = \dim(M)$. We suppose that $X \cdot Y = 0$. Does it follow that there exists a smooth homotopy $F\colon Y \times [0,1] \to M$ such that $F_0 = \mathrm{id}$ and $X \cap F_1(Y) = \varnothing$?

Exercise 43.5. Is the curve that goes twice around the Möbius band null-homotopic, i.e. is it homotopic to the constant curve?

Exercise 43.6.

(a) Show that every smooth map $f\colon S^1 \to S^2$ is null-homotopic, i.e. homotopic to a constant map.
(b) Show that S^2 not diffeomorphic to $S^1 \times S^1$.
(c) Can you upgrade the argument to show that S^2 is not homeomorphic to $S^1 \times S^1$?

Exercise 43.7. In the Intersection Number Homotopy Invariance Theorem 43.6 we studied the homotopy invariance of the algebraic intersection number under the following fairly strong hypotheses:

(1) $f_0|_{\partial Y} = f_1|_{\partial Y}$.
(2) $f_0(\partial Y) \cap X = f_1(\partial Y) \cap X = \varnothing$.
(3) There exists a homotopy F rel ∂Y.

Formulate the weakest hypothesis on the behavior of f_0, f_1 and F on ∂Y and prove the corresponding theorem.

Exercise 43.8. Let M be a codimension-zero smooth submanifold of $\mathbb{R}^n$ which is a closed smooth manifold. Determine the number of components of $\mathbb{R}^n \setminus M$ in terms of the number of components of M.

Exercise 43.9. Let M be a smooth manifold. For $i = 1, \dots, k$ let Y_i be a compact smooth manifold and let $f_i \colon Y_i \to M$ be a proper smooth embedding. Show that there exist proper smooth embeddings $\widetilde{f}_i \colon Y_i \to M$, $i = 1, \dots, k$ with the following properties:

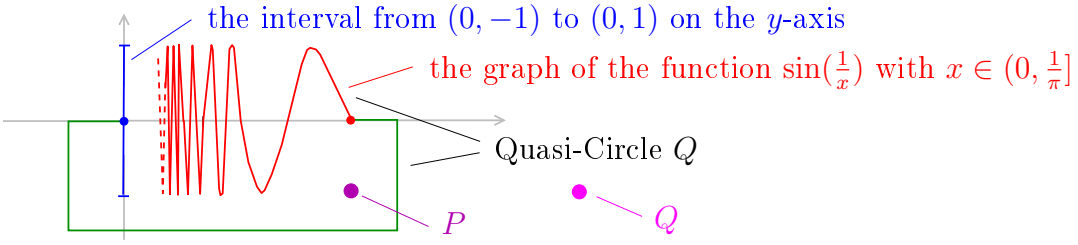
(1) Each $\widetilde{f}_i$ is smoothly isotopic to f_i.
(2) For any $i \neq j \in \{1, \dots, k\}$ we have $\widetilde{f}_i(Y_i) \pitchfork \widetilde{f}_j(Y_j)$.

Exercise 43.10. Let $\varphi \colon S^1 \to \mathbb{R}^2$ be a smooth embedding. Show that there exist distinct three points $x, y, z \in S^1$ such that $\varphi(x), \varphi(y), \varphi(z)$ from an equilateral triangle.
Hint. Use the Smooth Jordan-Brouwer Separation Theorem 43.11 for $n = 1$. Let $n \in \mathbb{N}$.

Exercise 43.11. Let

$$S \;:=\; \big\{(0, y) \,\big|\, y \in [-1, 1]\big\} \cup \big\{(x, \sin(\tfrac{1}{x})) \,\big|\, x \in (0, \tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2$$

be the "Topologist's Sine Curve" from page 164. As on page 276 we turn the Topologist's Sine curve into the *Quasi-Circle* Q by connecting the point $(0, 0)$ with $(\frac{1}{\pi}, 0)$ via the green curve shown in the figure below. We consider the points $A = (\frac{1}{\pi}, -1)$ and $B = (2, -1)$.

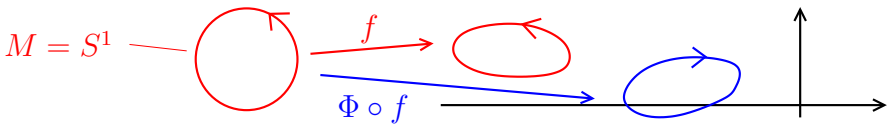


(a) Given $\epsilon > 0$ we consider the thickened up topological space

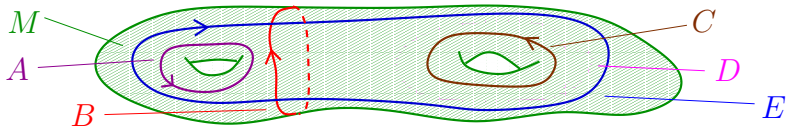
$$Q_\epsilon \;:=\; \{P \in \mathbb{R}^2 \,|\, \text{there exists } x \in Q \text{ with } d(x, P) < \epsilon\}.$$

Show that for every $\epsilon > 0$ there exists a smooth curve $\varphi \colon S^1 \to Q_\epsilon$ such that A and B lie in different path-components of $\mathbb{R}^2 \setminus \varphi(S^1)$.
Hint. Use the Smooth Jordan-Brouwer Separation Theorem 43.11.

(b) Show that there is no path $f \colon [0, 1] \to \mathbb{R}^2 \setminus Q$ from A to B.
Hint. By Exercise 5.30 we know that Q is compact. Lemma 6.3 might come in handy.



(c) Show that $\mathbb{R}^2 \setminus Q$ has precisely two path components.



Exercise 43.12. Let M be the smooth manifold that is obtained from the open disk B^2 by removing the three points $(0, -\frac{1}{2}), (0, 0)$ and $(0, \frac{1}{2})$. Show that there is no *proper* smooth embedding $f \colon M \to \mathbb{R}^2$.
Remark. This exercise can be viewed as the complement of Exercise 11.13.

Exercise 43.13. Let M be a closed connected non-empty n-dimensional smooth manifold and let $f \colon M \to \mathbb{R}^{n+1}$ be a smooth embedding. Furthermore let $\Phi \colon \mathbb{R}^{n+1} \to \mathbb{R}^{n+1}$ be an orientation-preserving diffeomorphism. Show that the smooth embeddings $f \colon M \to \mathbb{R}^{n+1}$ and $\Phi \circ f \colon M \to \mathbb{R}^{n+1}$ are not smoothly isotopic.

Hint. You could try to get the Generalized Smooth Jordan-Brouwer Separation Theorem 43.10 into the game.

Exercise 43.14. We consider the smooth manifold M together with the oriented submanifolds A, B, C, D and E are that are shown in the figure below. Show that the smooth submanifolds a pairwise non isotopic.

Exercise 43.15. Let $g \in \mathbb{N}_0$ and let Σ_g be the orientable surface of genus g. We equip Σ_g with some orientation. For the purpose of this exercise, given a closed oriented 1-dimensional submanifold $C \subset \Sigma_g$ we define the self-intersection number $C \cdot C := 0$. What is the maximal $k \in \mathbb{N}_0$ such that there exist closed oriented 1-dimensional submanifolds $A_1, \dots, A_k \subset \Sigma_g$ such that any two A_i, A_j with $i \neq j$ are transverse and such that the matrix $(A_i \cdot A_j)_{i,j=1,\dots,k}$ has non-zero determinant?
Remark. With the current techniques it is perhaps difficult to show that you have achieved the maximal k, but at least you can try to aim for the highest k possible.

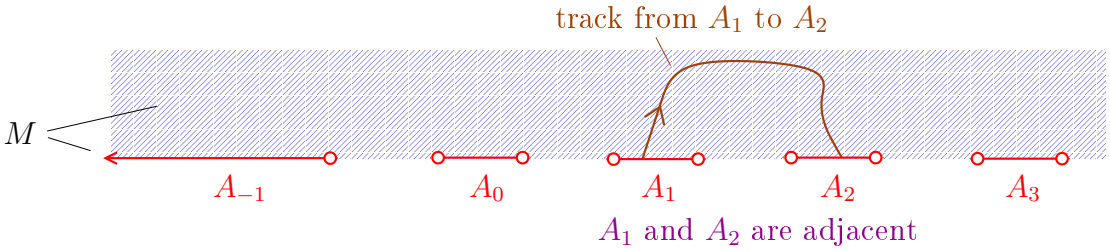
Exercise 43.16. We set

$$\begin{aligned} H &:= \{(x,y) \in \mathbb{R}^2 \,|\, y > 0\} && \text{the open half-plane} \\ A_{-1} &:= \{(x,0) \,|\, x < 0\} \\ \text{and for } k \in \mathbb{N}_0 \text{ we set } A_k &:= \{(x,0) \,|\, x \in (2k+1, 2k+2)\}, \\ \text{finally we set} M &:= H \cup (A_{-1} \cup A_0 \cup A_1 \cup \dots). \end{aligned}$$

We need to introduce some more language:

- Let $k \neq l$. A *track* from A_k to A_l is a connected oriented proper 1-dimensional smooth manifold T of M such that $\partial T = \{-P\} \cup \{Q\}$ where $P \in A_k$ and $Q \in A_l$.
- We say that two components A_k and A_l of ∂M are *adjacent* if there exists a track T from A_k to A_l such that all other components of ∂M are contained in one component of $M \setminus T$.

Now we turn to the actual problems:



(a) Show that $M := H \cup (A_{-1} \cup A_0 \cup A_1 \cup \dots)$ is a 2-dimensional smooth submanifold with $\partial M = A_{-1} \cup A_0 \cup A_1 \cup \dots$.

(b) Show that for any $k \neq l$ in $\mathbb{Z}_{\geq -1}$ the corresponding components A_k and A_l are adjacent if and only if $k - l \in \{-1, 1\}$.

(c) Let $f \colon M \to M$ be a self-diffeomorphism. Show that for each $k \in \mathbb{Z}_{\geq -1}$ we have $f(A_k) = A_k$.
Hint. Note that adjacency is preserved by diffeomorphisms.

(d) Show that every diffeomorphism of M is orientation-preserving.
Hint. Look at intersection numbers of tracks between components.

Remark. You can use the fact, which we will show later in Exercise 55.19, that any two tracks from A_k to A_l are properly isotopic.

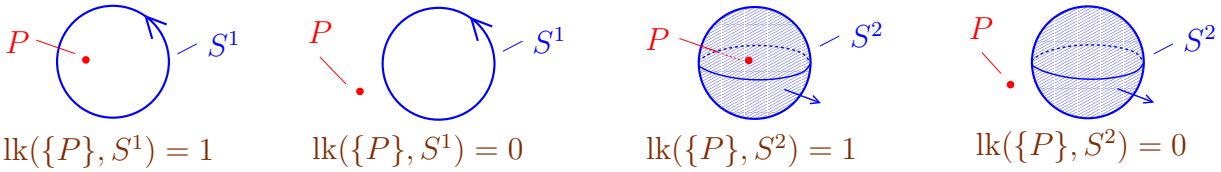
44. Linking numbers

In this short chapter we will use the techniques that we have developed over the last chapters to introduce and discuss linking numbers of suitable disjoint submanifolds in $\mathbb{R}^n$. To define the linking numbers it is convenient to generalize slightly the notion of the degree of a map between closed oriented connected smooth manifolds.

Definition. Let M be a closed oriented smooth manifold with components $M_1, \dots, M_k$ and let N be a closed oriented connected non-empty smooth manifold of the same dimension. Given any map $f\colon M \to N$ we define

$$\deg(f) \;:=\; \sum_{i=1}^{k} \underbrace{\deg(f|_{M_i}\colon M_i \to N)}_{\text{defined on page 899}}.$$

Now we can turn to the key definition of this section.

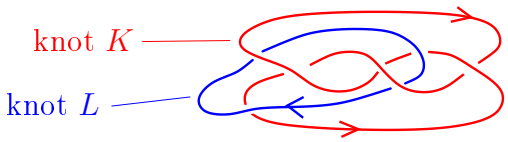


Definition. Let $n \in \mathbb{N}$. Let K and L be disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ with $\dim(K) + \dim(L) = n - 1$. We define the linking number $\operatorname{lk}(K, L)$ as[431]

$$\operatorname{lk}(K,L) \;:=\; (-1)^{\dim(L)} \cdot \deg \begin{pmatrix} K \times L & \to & S^{n-1} \\ (x,y) & \mapsto & \frac{x-y}{\|x-y\|} \end{pmatrix}$$

Remark. There are many ways think about the linking number. In particular on page 2865 we will also give an alternative definition of the linking number which we will discuss in detail in Section 131.4. In the Linking Number Reformulation Proposition 131.16 we will see that our two definitions of the linking number agree. Our sign convention is chosen in a way such that the latter definition becomes pretty, which unfortunately forces us to add the slightly ugly "$(-1)^{\dim(L)}$"-factor to the above definition.

Example. Let $n \in \mathbb{N}$, let $L = S^{n-1} \subset \mathbb{R}^n$ be the sphere equipped with the standard orientation from page 681 and let $K = \{P\}$ be the 0-dimensional submanifold that consists of a single point $P \in \mathbb{R}^n \setminus S^{n-1}$ and that is equipped with the orientation $+1$. In Exercise 44.3 we will see that



$$\operatorname{lk}(\{P\}, S^{n-1}) \;=\; \begin{cases} 1, & \text{if } P \in B^n, \\ 0, & \text{otherwise.} \end{cases}$$

Our main interest will be in the case $n = 3$ and $\dim(K) = \dim(L) = 1$. It is thus convenient to introduce the following definition.

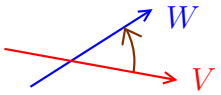
[431] Here we endow $K \times L$ with the product orientation that we defined on page 695 and we equip S^{n-1} with the standard orientation that we introduced on page 681. Thus we see that $K \times L$ is a closed oriented smooth manifold of dimension $n - 1$. Therefore it makes sense to talk of the degree of a map to S^{n-1}.

Definition. An oriented knot in $\mathbb{R}^3$ is an oriented submanifold of $\mathbb{R}^3$ that is diffeomorphic to S^1.

what is $\mathrm{lk}(K,L)$?

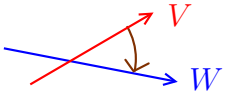
To formulate our next proposition we will need the following notation and definition.

Definition.



(1) Let $n \in \mathbb{N}$. We denote by

$$\begin{array}{rcl} \pi\colon \mathbb{R}^n & \to & \mathbb{R}^{n-1} \\ (x_1,\dots,x_n) & \mapsto & (x_1,\dots,x_{n-1}) \end{array} \quad \text{and} \quad \begin{array}{rcl} z\colon \mathbb{R}^n & \to & \mathbb{R} \\ (x_1,\dots,x_n) & \mapsto & x_n \end{array}$$

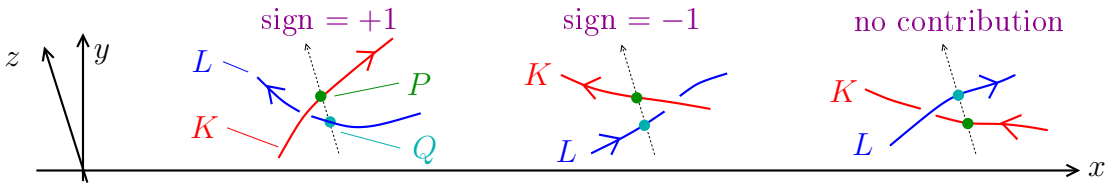


the projections onto the first $n-1$ coordinates and onto the last coordinate.

(2) Given two oriented vector subspaces V, W of $\mathbb{R}^m$ with $\dim(V)+\dim(W)=m$ and with $V+W=\mathbb{R}^m$ we set

$$\mathrm{sign}(V,W) := \begin{cases} +1, & \text{if } V\times W \to \mathbb{R}^m,\ (v,w)\mapsto v+w \text{ is orientation-preserving,} \\ -1, & \text{otherwise.} \end{cases}$$

$\mathrm{sign}(V,W)=+1$

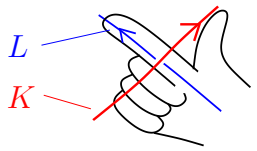


$\mathrm{sign}(V,W)=-1$

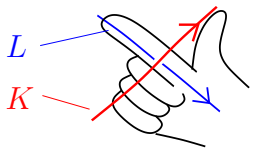
The next proposition presents one way to calculate linking numbers. In "real life" it gives a handy way to calculate the linking number of two disjoint oriented knots in $\mathbb{R}^3$. We will also make use of it for a more theoretical purpose.

Proposition 44.1. Let K and L be two disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ with $\dim(K)+\dim(L)=n-1$. We assume that for each $P\in K$ and $Q\in L$ with $\pi(P)=\pi(Q)$ we have $\pi(\widetilde{\mathrm{T}}_P K)+\pi(\widetilde{\mathrm{T}}_Q L)=\mathbb{R}^{n-1}$. Then there are only finitely many $(P,Q)\in K\times L$ with $\pi(P)=\pi(Q)$ and with $z(P)>z(Q)$. Furthermore[432]

$$\mathrm{lk}(K,L) \;=\; \sum_{\substack{P\in K \text{ and } Q\in L \\ \text{with } \pi(P)=\pi(Q) \text{ and} \\ z(P)>z(Q)}} \mathrm{sign}(\pi(\widetilde{\mathrm{T}}_P K), \pi(\widetilde{\mathrm{T}}_Q L)).$$



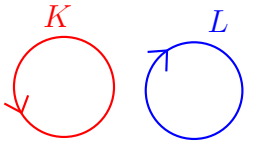
Example. We want to explain in slightly more detail how Proposition 44.1 can be used to calculate the linking number between two disjoint oriented knots K and L in $\mathbb{R}^3$. In



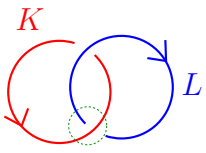
[432] Note that $\dim(K)+\dim(L)=n-1$ and $\pi(\widetilde{\mathrm{T}}_P K)+\pi(\widetilde{\mathrm{T}}_Q L)=\mathbb{R}^{n-1}$ imply that the restriction of π to $\widetilde{\mathrm{T}}_P K$ and to $\widetilde{\mathrm{T}}_Q L$ are both monomorphisms. Thus we can view $\pi(\widetilde{\mathrm{T}}_P K)$ and $\pi(\widetilde{\mathrm{T}}_Q L)$ as oriented vector subspaces of $\mathbb{R}^{n-1}$.

practice the knots K and L are given by a diagram, i.e. the images of the knots in the xy-plane and one remembers which z-coordinate is larger. In this setting Proposition 44.1 says the following:

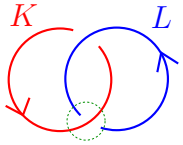
(1) To each point where K crosses over L we assign $+1$ if the following "right hand rule" is satisfied: if the thumb of the right hand points into the direction of the knot K, then the fingers point in the direction of the knot L. Otherwise we assign -1 to such a crossing point.
(2) We sum up over all signs defined in (1) and we obtain the linking number $\mathrm{lk}(K, L)$ of K and L.



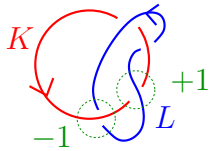
contributes $+1$ to $\mathrm{lk}(K, L)$



contributes -1 to $\mathrm{lk}(K, L)$



In practice it is now straightforward to calculate linking numbers of disjoint oriented knots in $\mathbb{R}^3$. Some calculations are shown in the following figure.



linking number $= 0$

linking number $= +1$

linking number $= -1$

linking number $= 0$

Proof of Proposition 44.1. We set $k := \dim(K)$ and $l := \dim(L)$. We consider the map

$$\begin{array}{rcl} \Theta\colon K \times L & \to & S^{n-1} \\ (P, Q) & \mapsto & \frac{P-Q}{\|P-Q\|}. \end{array}$$

Claim.

(1) For any $(P, Q) \in K \times L$ we have $\widetilde{\mathrm{T}}_{(P,Q)}(K \times L) = \widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L \subset \mathbb{R}^n \times \mathbb{R}^n$.
(2) For any $(P, Q) \in K \times L$ with $P - Q = \lambda \cdot e_n$ for some $\lambda > 0$ the map

$$\mathrm{D}(\pi \circ \Theta)_{(P,Q)}\colon \widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L \ \to \ \widetilde{\mathrm{T}}_{\pi(\Theta(P,Q))}\mathbb{R}^{n-1} = \mathbb{R}^{n-1}$$

is given by

$$(v, w) \ \mapsto \ \lambda \cdot (\pi(v) - \pi(w)).$$

(3) Given $P \in K$ and $Q \in L$ the following two statements are equivalent:
   (a) $\pi(P) = \pi(Q)$ and $z(P) > z(Q)$,
   (b) $\Theta(P, Q) = e_n$.
(4) $e_n \in S^{n-1}$ is a regular value of Θ.
(5) There are only finitely many $(P, Q) \in K \times L$ with $\pi(P) = \pi(Q)$ and with $z(P) > z(Q)$.

Proof.

(1) We know by Exercise 23.4 that $\widetilde{\mathrm{T}}_{(P,Q)}(K \times L) = \widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L$.

(2) Let $(P,Q) \in K \times L$ with $P - Q = \lambda \cdot e_n$ where $\lambda > 0$. We introduce the following two maps:

$$\begin{array}{rcl} \tau\colon \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}^n \\ (v,w) & \mapsto & v - w \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \nu\colon \mathbb{R}^n \setminus \{0\} & \to & S^{n-1} \\ x & \mapsto & \frac{x}{\|x\|}. \end{array}$$

Let $v \in \widetilde{\mathrm{T}}_P K$ and $w \in \widetilde{\mathrm{T}}_Q L$. We perform the following calculation:

$$\begin{array}{rcl} \mathrm{D}(\pi \circ \Theta)_{(P,Q)}(v,w) & \overset{\text{by definition of } \Theta}{\underset{\uparrow}{=}} & \mathrm{D}(\pi \circ \nu \circ \tau)_{(P,Q)}(v,w) \\ & = & \lambda \cdot (\pi \circ \tau)(v,w) \end{array} \quad \begin{array}{rcl} \overset{\text{Chain rule and since } \pi \text{ is linear}}{\underset{\downarrow}{=}} & \pi \circ (\mathrm{D}\nu_{\lambda \cdot e_n} \circ \mathrm{D}\tau_{(P,Q)})(v,w) \\ = & \lambda \cdot (\pi(v) - \pi(w)). \end{array}$$

explicit calculation of $\mathrm{D}\nu_{\lambda \cdot e_n}$ and since τ is linear

(3) This statement follows easily from the definitions.

(4) Note that $\mathrm{D}(\pi|_{S^{n-1}})_{e_n}\colon \widetilde{\mathrm{T}}_{e_n} S^{n-1} \to \mathbb{R}^{n-1}$ is an isomorphism. It follows from this observation, together with (2) and (3) and our hypothesis in the proposition, that e_n is a regular value of Θ.

(5) It follows from (3) and (4) and the Stack of Records Lemma 26.2, that there are only finitely $(P,Q) \in K \times L$ with $\pi(P) = \pi(Q)$ and with $z(P) > z(Q)$. ⊞

Before we move on to the actual calculation of the linking number let us introduce one more piece of notation: given any isomorphism $\varphi\colon V \to W$ between oriented vector spaces we write

$$\deg(\varphi) \;:=\; \begin{cases} +1, & \text{if } \varphi\colon V \to W \text{ is orientation-preserving,} \\ -1, & \text{if } \varphi\colon V \to W \text{ is orientation-reversing.} \end{cases}$$

Using this notation we calculate

$$\begin{array}{rcl} \mathrm{lk}(K,L) & \overset{\text{see above definition}}{\underset{\downarrow}{=}} & (-1)^l \cdot \deg \begin{pmatrix} K \times L \overset{\Theta}{\to} S^{n-1} \\ (x,y) \mapsto \frac{x-y}{\|x-y\|} \end{pmatrix} \overset{\text{by the definition of deg on page 899, since } e_n \text{ is a regular value}}{\underset{\downarrow}{=}} (-1)^l \cdot \sum_{(P,Q) \in \Theta^{-1}(e_n)} \deg(\widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L \xrightarrow{\mathrm{D}\Theta_{(P,Q)}} \widetilde{\mathrm{T}}_{e_n} S^{n-1}) \\ & \overset{\text{by the chain rule, and since by the definition of the standard orientation on } S^{n-1}\text{, see page 681, we see that the map } \mathrm{D}(\pi|_{S^{n-1}})_{e_n}\colon \widetilde{\mathrm{T}}_{e_n} S^{n-1} \to \mathbb{R}^{n-1} \text{ is an orientation-preserving isomorphism}}{\underset{\uparrow}{=}} & (-1)^l \cdot \sum_{(P,Q) \in \Theta^{-1}(e_n)} \deg(\mathrm{D}(\pi \circ \Theta)_{(P,Q)}\colon \widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L \to \mathbb{R}^{n-1}) \\ & \overset{\text{follows from Statement (2) of the claim, the fact that } z(P-Q) > 0 \text{ and the fact that } -\pi(w) = \pi(-w)}{\underset{\uparrow}{=}} & (-1)^l \cdot \sum_{(P,Q) \in \Theta^{-1}(e_n)} \deg \begin{pmatrix} \widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L \to \mathbb{R}^{n-1} \\ (v,w) \mapsto \pi(v) + \pi(-w) \end{pmatrix} \\ & \overset{\text{for the } l\text{-dimensional vector space } W = \widetilde{\mathrm{T}}_Q L \text{ the degree of the map } w \mapsto w \text{ equals } (-1)^l}{\underset{\uparrow}{=}} & \sum_{(P,Q) \in \Theta^{-1}(e_n)} \deg \begin{pmatrix} \widetilde{\mathrm{T}}_P K \times \widetilde{\mathrm{T}}_Q L \to \mathbb{R}^{n-1} \\ (v,w) \mapsto \pi(v) + \pi(w) \end{pmatrix} \overset{\text{by the definition of the sign}}{\underset{\uparrow}{=}} \sum_{(P,Q) \in \Theta^{-1}(e_n)} \mathrm{sign}(\pi(\widetilde{\mathrm{T}}_P K), \pi(\widetilde{\mathrm{T}}_Q L)). \end{array}$$

It follows from Statement (3) of the claim that the sum on the right hand side is precisely the sum on the right hand side of the proposition. ■

We continue with the development of the theory of linking numbers.

Proposition 44.2. Let K and L be disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ with $\dim(K)+\dim(L)=n-1$.

(1) If $F\colon (K\sqcup L)\times[0,1]\to\mathbb{R}^n$ is a smooth isotopy, then,

$$\operatorname{lk}(F_0(K),F_0(L)) \;=\; \operatorname{lk}(F_1(K),F_1(L)).$$

(2) We have the following equality

$$\operatorname{lk}(L,K) \;=\; (-1)^{\dim(K)\cdot\dim(L)+1}\cdot\operatorname{lk}(K,L).$$

Proof. We write $k=\dim(K)$ and $l=\dim(L)$.

(1) We consider the map

$$\begin{array}{rcl}\Xi\colon K\times L\times[0,1] & \to & S^2\\ (x,y) & \mapsto & \frac{F_t(x)-F_t(y)}{\|F_t(x)-F_t(y)\|}.\end{array}$$

Now we see that

$$\begin{array}{rcl}\operatorname{lk}(F_0(K),F_0(L)) &=& (-1)^l\cdot\deg(K\times L\xrightarrow{\Xi_0}S^2)\\ &\overset{\text{by the Degree Homotopy Invariance Theorem 38.3}}{\downarrow}&\\ &=& (-1)^l\cdot\deg(K\times L\xrightarrow{\Xi_1}S^2)\\ &=& \operatorname{lk}(F_1(K),F_1(L)).\end{array}$$

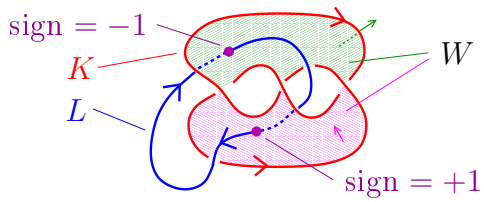
(2) We consider the three maps

$$\begin{array}{rcl}\Theta\colon K\times L & \to & S^{n-1}\\ (x,y) & \mapsto & \frac{x-y}{\|x-y\|}\end{array}\qquad\begin{array}{rcl}\tau\colon K\times L & \to & L\times K\\ (x,y) & \mapsto & (y,x)\end{array}\qquad\text{and}\qquad\begin{array}{rcl}\sigma\colon S^{n-1} & \to & S^{n-1}\\ z & \mapsto & -z.\end{array}$$

Then

$$\begin{array}{rcl}\operatorname{lk}(L,K) &\overset{\text{by definition}}{=}& (-1)^k\cdot\deg(\sigma\circ\Theta\circ\tau)\\ &=& (-1)^k\cdot(-1)^{k+l+1}\cdot\det(\Theta)\cdot(-1)^{k\cdot l}\\ &\overset{\text{by the Basics of Degree Lemma 38.8 and since}}{\uparrow}&\\ &&\sigma\text{ is orientation-preserving if and only if }n=k+l+1\text{ is even (see Exercise 25.5)}\\ &&\tau\text{ is orientation-preserving if and only if }k\cdot l\text{ is even (see Exercise 25.14)}\end{array}$$

$$\begin{array}{rcl}&\overset{\text{Degree Multiplicativity Theorem 38.4}}{=}&(-1)^k\cdot\deg(\sigma)\circ\deg(\Theta)\cdot\deg(\tau)\\ &=&(-1)^{k\cdot l+1}\cdot\operatorname{lk}(K,L).\end{array}$$



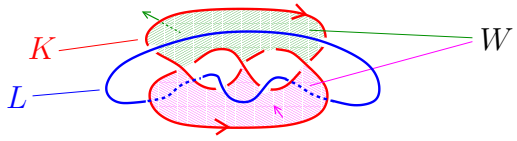
■

We conclude this chapter with the following proposition which can be very useful for calculating linking numbers of knots in $\mathbb{R}^3$.

Proposition 44.3. (Linking Numbers-via-Intersection Numbers Proposition) Let $n\in\mathbb{N}$ and let K and L be two disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ such that $\dim(K)+\dim(L)=n-1$. Suppose that there exists a compact orientable smooth submanifold W of $\mathbb{R}^n$ with $\partial W=K$ (as oriented smooth manifolds). If W intersects L transversally, then

$$\operatorname{lk}(K,L) \;=\; (-1)^{n+1}\cdot(W\cdot L)$$

where $W\cdot L$ denotes the algebraic intersection number that we introduced on page 989.



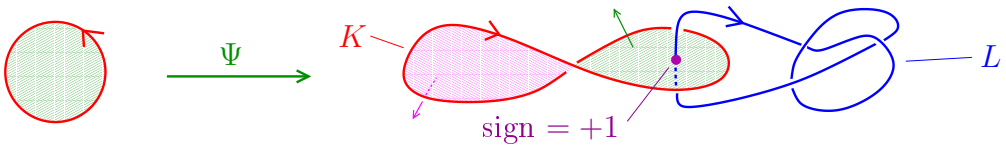
$$\operatorname{lk}(K,L)=W\cdot L=-1+1=0$$

Remark. In Proposition 131.13 we will give an alternative proof of the Linking Numbers-via-Intersection Numbers Proposition 44.3 in the special case that $n=3$.

We will prove the Linking Numbers-via-Intersection Numbers Proposition 44.3 by first considering two special cases.

Auxiliary Lemma 44.4. Let $n \in \mathbb{N}$ and let K and L be closed oriented smooth manifolds of $\mathbb{R}^n$ with $\dim(K) + \dim(L) = n - 1$. If there exists a compact orientable smooth submanifold W of $\mathbb{R}^n$ such that $\partial W = K$ (as oriented smooth manifolds) and which is disjoint from L, then $\mathrm{lk}(K, L) = 0$.

Proof of Lemma 44.4. Since W is disjoint from L we can consider the map



$$\begin{array}{rcl} \Theta\colon W \times L & \to & S^{n-1} \\ (x, y) & \mapsto & \frac{x-y}{\|x-y\|}. \end{array}$$

By Sard's Theorem 31.1 we know that $\Theta|_{K\times L}\colon K \times L \to S^{n-1}$ has a regular value $P \in S^{n-1}$. Now we see that[433]

$$\mathrm{lk}(K, L) \underset{\text{by definition}}{=} (-1)^{\dim(L)} \cdot \deg(\Theta|_{K\times L} \to S^{n-1}) \overset{\text{see page 989}}{=} (-1)^{\dim(L)} \cdot (\{P\} \cdot \Theta|_{K\times L}) \underset{\text{by the Intersection-Number Zero-if-Extends Proposition 43.4}}{=} 0. \qquad \blacksquare$$

Auxiliary Lemma 44.5. Let $n \in \mathbb{N}$ and let K and L be two disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ with $\dim(K) + \dim(L) = n - 1$. We suppose that there exists a smooth embedding $\Psi\colon \overline{B}^{\dim(K)+1} \to \mathbb{R}^n$ such that $\Psi\colon S^{\dim(K)} \to K$ is a diffeomorphism of oriented smooth manifolds. If $\Psi(\overline{B}^{k+1})$ intersects L transversally, then

$$\mathrm{lk}(K, L) = (-1)^{n+1} \cdot (\Psi(\overline{B}^{k+1}) \cdot L).$$

Proof of Lemma 44.5. First we consider a special case. Afterwards we will reduce the general case to the special case.

Claim 1. Let $\iota\colon \overline{B}^{k+1} \to \mathbb{R}^n$ be the standard smooth embedding that is given by $x \mapsto (x, 0)$. Furthermore let $\widetilde{L}$ be a closed oriented smooth submanifold of $\mathbb{R}^n$ that is disjoint from $\widetilde{K} := \iota(S^k)$ and with $\dim(\widetilde{L}) = n - k - 1$. If $\widetilde{L}$ is transverse to $\overline{B}^{k+1} \times \{0\}$ and to $S^k \times \{0\} \times \mathbb{R}$, then

$$\mathrm{lk}(\widetilde{K}, \widetilde{L}) = (-1)^{n+1} \cdot (\iota(\overline{B}^{k+1}) \cdot \widetilde{L}).$$

Proof. Since $\widetilde{L}$ is compact there exists an $r < 0$ such that $\widetilde{L} \subset \mathbb{R}^{n-1} \times (r, \infty)$. Using the Smooth Transition Function Lemma 19.4 one can easily show that there exists a smooth embedding

$$\begin{array}{rcl} \gamma\colon [0, 1] & \to & \mathbb{R}^2 \\ t & \mapsto & \gamma(t) = (\alpha(t), \beta(t)) \end{array}$$

[433] The argument becomes even more direct if one has solved Exercise 38.11.

with the following properties:

(1) For $t \in [0, \frac{1}{4}]$ we have $\gamma(t) = (t, -r-1)$.
(2) For $t \in [\frac{1}{4}, \frac{3}{4}]$ we have $\gamma(t) \in [\frac{1}{4}, 1] \times [-r-1, -r]$.
(3) For $t \in [\frac{3}{4}, 1]$ we have $\gamma(t) = (1, -r \cdot (1 - (t - \frac{3}{4})))$.

Next we consider the smooth map

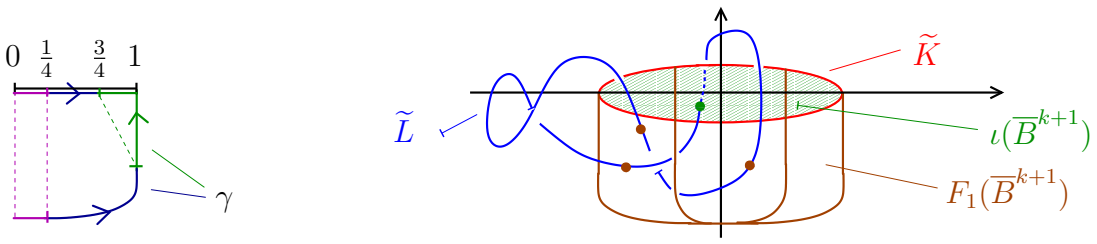
$$\begin{array}{rcl} \overline{B}^{k+1} \times [0,1] & \to & \mathbb{R}^n \\ (v,t) & \mapsto & \begin{cases} (v, 0, \ldots, 0, t \cdot (r+1)), & \text{if } \|v\| < \frac{1}{4}, \\ (\frac{v}{\|v\|} \cdot (\|v\| \cdot (1-t) + t \cdot \alpha(\|v\|)), 0, \ldots, 0, t \cdot \beta(\|v\|)), & \text{if } \|v\| > 0. \end{cases} \end{array}$$

We make the following observations and preparations:

(1) Note that $F_1(\overline{B}^{k+1}) \cap (\mathbb{R}^{n-1} \times (-\infty, 0]) = S^k \times \{0\} \times (-r, 0]$.
(2) As above we denote by $\pi \colon \mathbb{R}^n \to \mathbb{R}^{n-1}$ the projection onto the first $n-1$ coordinates.
(3) Since $\widetilde{L}$ is transverse to $S^k \times \{0\} \times \mathbb{R}$ we obtain from the Submanifold Transversal Intersection Theorem 42.1 that $(S^k \times \{0\} \times \mathbb{R}) \cap \widetilde{L}$ is a compact 0-dimensional submanifold, i.e. it is a finite set. We denote the intersection points of $F_1(\overline{B}^{k+1})$ with $\widetilde{L}$ by $(x_i, 0, t_i) \in S^k \times \{0\} \times (-r, 0)$, $1, \ldots, m$.
(4) Note that the points $(x_i, 0, t_i) \in \widetilde{L}$, $i = 1, \ldots, m$ are precisely the points on $\widetilde{L}$ such that $\pi(\widetilde{K}) \cap \pi(\widetilde{L}) \neq \varnothing$ and such that the last coordinate of the point on $\widetilde{K}$ is greater than the last coordinate of the point on $\widetilde{L}$.
(5) It follows from the Boundary Orientation Lemma 25.17 (4) together with the Product Orientation Proposition 25.22 (5) that the map $\Theta \colon (\frac{3}{4}, 1] \times S^k \to \overline{B}^{k+1}$ given by $(t, v) \mapsto t \cdot v$ is orientation-preserving.
(6) It follows easily from (5) that the map

$$\begin{array}{rcl} F_1 \colon \{v \in \overline{B}^{k+1} \mid \|v\| > \frac{3}{4}\} & \to & S^k \times \{0\} \times [0, r) \\ v & \mapsto & (\frac{v}{\|v\|}, 0, \ldots, 0, -r \cdot (1 - (\|v\| - \frac{3}{4}))) \end{array}$$

is *orientation-reversing*.
(7) We have $\det \begin{pmatrix} 0 & \mathrm{id}_{n-1} \\ 1 & 0 \end{pmatrix} = (-1)^n$.
(8) Let $i \in \{1, \ldots, m\}$. It follows easily from (6) and (7) and the various definitions that



$$\underbrace{\begin{array}{c}\text{sign of the intersection point} \\ (x_i, 0, t_i) \text{ of } F_1(\overline{B}^{k+1}) \text{ and } L\end{array}}_{\text{as defined on page 989}} = (-1)^{n+1} \cdot \underbrace{\mathrm{sign}(\pi(\widetilde{\mathrm{T}}_{(x_i,0,t)}\widetilde{K}), \pi(\widetilde{\mathrm{T}}_{(x_i,0,t)}\widetilde{L}))}_{\text{as defined on page 1008}}$$

Then we see that

$$\iota(\overline{B}^{k+1}) \cdot \widetilde{L} = F_0(\overline{B}^{k+1}) \cdot \widetilde{L} \underset{\uparrow}{=} F_1(\overline{B}^{k+1}) \cdot \widetilde{L} \underset{\uparrow}{=} \sum_{i=1}^{m} \mathrm{sign}(x_i) \underset{\uparrow}{=} (-1)^{n+1} \cdot \mathrm{lk}(\widetilde{K}, \widetilde{L}).$$

Intersection Number Homotopy Invariance Theorem 43.6 — Lemma 43.1 — follows from (8) and Proposition 44.1 ⊞

The statement of the following Claim 2 is identical to the statement of Claim 1, except that we will manage to drop the hypothesis that $\widetilde{L}$ is transverse to $S^k \times \{0\} \times \mathbb{R}$.

Claim 2. Let $\widehat{L}$ be a closed oriented smooth submanifold of $\mathbb{R}^n$ that is disjoint from the submanifold $\widetilde{K} := \iota(S^k)$ and with $\dim(\widehat{L}) = n-k-1$. If $\widehat{L}$ is transverse to $\overline{B}^{k+1} \times \{0\}$, then
$$\mathrm{lk}(\widetilde{K}, \widehat{L}) \;=\; (-1)^{n+1} \cdot (\iota(\overline{B}^{k+1}) \cdot \widehat{L}).$$

Proof. It follows easily from the Transversality-Extends-to-Neighborhood Lemma 42.9 together with the Transversality Theorem 42.5, applied to the smooth manifold $M = \mathbb{R}^n \setminus (S^k \times \{0\})$, that there exists a smooth isotopy $G\colon \widehat{L} \times [0,1] \to \mathbb{R}^n$ rel an open neighborhood of $\widehat{L} \cap (\overline{B}^{k+1} \times \{0\})$, such that $G_0 = \mathrm{id}_{\widehat{L}}$ and such that $(S^k \times \{0\} \times \mathbb{R}) \pitchfork G_1(\widehat{L})$. We set $\widetilde{L} := G_1(\widehat{L})$. Now we see that
$$\mathrm{lk}(\widetilde{K}, \widehat{L}) \underset{\text{Proposition 44.2}}{\uparrow=} \mathrm{lk}(\widetilde{K}, \widetilde{L}) \underset{\text{Claim 1}}{\uparrow=} (-1)^{n+1} \cdot (\iota(\overline{B}^{k+1}) \cdot \widetilde{L}) \underset{\text{since } \widetilde{L} = \widehat{L} \text{ in a neighborhood of } \iota(\overline{B}^{k+1})}{\uparrow=} (-1)^{n+1} \cdot (\iota(\overline{B}^{k+1}) \cdot \widehat{L}).$$
⊞

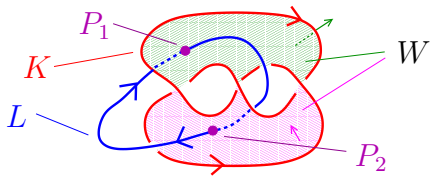
Now we finally turn to the general setting of the proposition. Thus let K and L be two disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ with $\dim(K) + \dim(L) = n-1$. We set $k := \dim(K)$. We suppose that there exists a smooth embedding $\Psi\colon \overline{B}^{k+1} \to \mathbb{R}^n$ such that $\Psi\colon S^k \to K$ is a diffeomorphism of oriented smooth manifolds. It follows from the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 that there exists a diffeotopy $F\colon \mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ such that $F_0 = \mathrm{id}$ and such that $F_1 \circ \Psi\colon \overline{B}^{k+1} \to \mathbb{R}^n$ is the standard embedding $\iota\colon \overline{B}^{k+1} \to \mathbb{R}^n$ given by $x \mapsto (x, 0)$. Note that it follows from $F_0 = \mathrm{id}$ and the Smooth Isotopy-Orientation Proposition 34.2 that F_1 is orientation-preserving. Now we see that
$$\mathrm{lk}(K, L) \underset{\text{Proposition 44.2}}{\uparrow=} \mathrm{lk}(F_1(K), F_1(L)) \underset{\substack{\text{by Claim 2 since} \\ F_1(K) = \widetilde{K}}}{\uparrow=} \iota(\overline{B}^{k+1}) \cdot F_1(L) \underset{\substack{\text{Lemma 43.3 applied to the} \\ \text{orientation-preserving diffeomorphism } F_1^{-1}}}{\uparrow=} \Psi(\overline{B}^{k+1}) \cdot L.$$
■

Proof of the Linking Numbers-via-Intersection Numbers Proposition 44.3. Let K and L be disjoint closed oriented smooth submanifolds of $\mathbb{R}^n$ with $\dim(K)+\dim(L) = n-1$. We suppose that there exists a compact orientable smooth submanifold W of $\mathbb{R}^n$ with $\partial W = K$ and with $W \pitchfork L$.

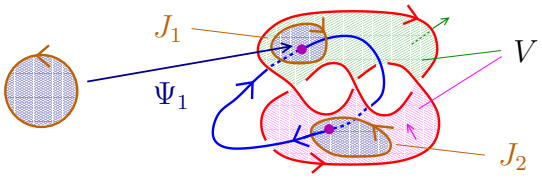
It follows from the Submanifold Transversal Intersection Theorem 42.1 that $W \cap L$ is a compact 0-dimensional submanifold of W. This means that $W \cap L$ consists of finitely many points $P_1, \ldots, P_m \in W \setminus \partial W$.

We set $k := \dim(K)$. Evidently we can pick orientation-preserving smooth embeddings $\Psi_i\colon \overline{B}^{k+1} \to W \setminus \partial W$, $i = 1, \ldots, m$, with disjoint images, and such that $\Psi_i(0) = P_i$ for

$i = 1, \dots, m$. We set $V := W \setminus \bigcup_{i=1}^{m} \Psi_i(B^{k+1})$ and for $i = 1, \dots, m$ we set $J_i := \Psi_i(S^k)$. We equip J_i with the orientation coming from the standard orientation of S^k.



By the Codimension-Zero Smooth Embedding Proposition 24.16 we know that V is a compact codimension-zero submanifold of W. If we equip V with the orientation coming from W, then it follows from Exercise 25.19 that $\partial V = K \cup \bigcup_{i=1}^{m} (-J_i)$. Finally we see that



$$\operatorname{lk}(K, L) \underset{\uparrow}{=} \operatorname{lk}\Big(K \cup \bigcup_{i=1}^{m}(-J_i), L\Big) + \sum_{i=1}^{m} \operatorname{lk}(J_i, L) \underset{\uparrow}{=} 0 + \sum_{i=1}^{m} \Psi_i(\overline{B}^{k+1}) \cdot L \underset{\uparrow}{=} W \cdot L$$

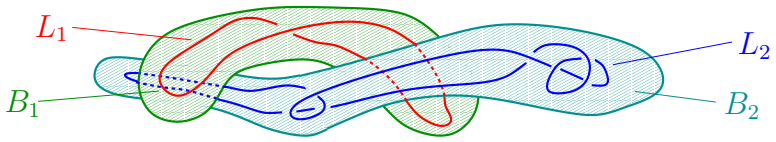
follows easily from the definition of the linking number and basic properties of the degree

by Lemma 44.4 since $\partial V = K \cup \bigcup_{i=1}^{m}(-J_i)$ and by Lemma 44.5, since $J_i = \partial \Psi_i(\overline{B}^{k+1})$

since $V \cap L = \varnothing$ ■

Exercises for Chapter 44.

Exercise 44.1. An *oriented link in* $\mathbb{R}^3$ is a closed oriented smooth submanifold of $\mathbb{R}^3$. We say an m-component link $L \subset \mathbb{R}^3$ is a *trivial link* if it bounds m disjoint smoothly embedded disks in $\mathbb{R}^3$. It follows immediately from the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 that all m-component trivial links are in fact smoothly isotopic.



(a) Give an example of two disjoint knots K, L in $\mathbb{R}^3$ such that K and L are smoothly isotopic to the trivial knot, such that $\operatorname{lk}(K, L) = 0$ but such that $K \sqcup L$ is not smoothly isotopic to a trivial link.

(b) Give an example of a 3-component link $L = L_1 \cup L_2 \cup L_3$ in $\mathbb{R}^3$ such that any two components are isotopic to a trivial link but such that L itself is not smoothly isotopic to a trivial link.

(c) Generalize (b) from $m = 3$ to any $m \in \mathbb{N}_{\geq 3}$.

Remark. We lack the tools right now to show that a link with zero linking numbers is not smoothly isotopic to a trivial link. Thus with the methods we have developed so far we cannot really give a complete answer to the challenges. But this should not prevent the reader from trying to find examples.

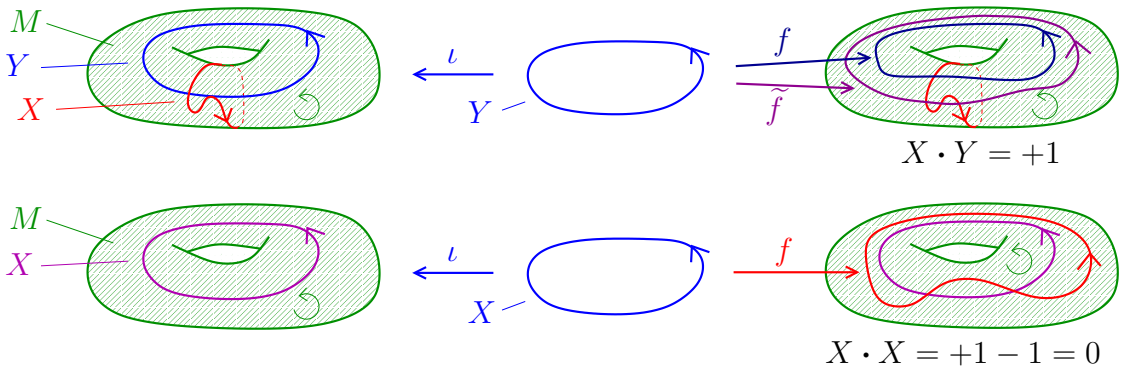
Exercise 44.2. An *oriented link in* $\mathbb{R}^3$ is a closed oriented smooth submanifold of $\mathbb{R}^3$. An m-component link $L = L_1 \sqcup \dots \sqcup L_m \subset \mathbb{R}^3$ is called *split link* if there exist disjoint smoothly embedded closed 3-dimensional balls $B_1, \dots, B_m \subset \mathbb{R}^3$ such that each L_i is contained in B_i. Show that if $L = L_1 \sqcup \dots \sqcup L_m \subset \mathbb{R}^3$ is a split link, then for any $i \neq j$ we have $\operatorname{lk}(L_i, L_j) = 0$.

Exercise 44.3. Let $n \in \mathbb{N}$, let $L = S^{n-1} \subset \mathbb{R}^n$ be the sphere equipped with the standard orientation from page 681 and let $K = \{P\}$ be the 0-dimensional submanifold that consists of a single point $P \in \mathbb{R}^n \setminus S^{n-1}$ and that is equipped with the orientation $+1$. Show that

$$\mathrm{lk}(\{P\}, S^{n-1}) \;=\; \begin{cases} 1, & \text{if } P \in B^n, \\ 0, & \text{otherwise.} \end{cases}$$

45. The smooth Euler characteristic and the Smooth Poincaré-Hopf Theorem

45.1. **The smooth Euler characteristic.** The following definition generalizes the definition from page 989 of the algebraic intersection number of two transverse submanifolds to the non-transverse case.



Definition. Let M be an oriented smooth manifold.

(1) Let X and Y be two closed oriented submanifolds of M of complementary dimension, i.e. we have $\dim(X) + \dim(Y) = \dim(M)$. Let $\iota\colon Y \to M$ be the inclusion map. By the Transversality Theorem 42.5 the map ι is smoothly isotopic to a smooth embedding $f\colon Y \to M$ with $X \pitchfork f$. It follows from the Intersection Number Homotopy Invariance Theorem 43.5 that

$$X \cdot Y \;:=\; X \cdot f \;\in\; \mathbb{Z}$$

does not depend on the choice of f. We refer to $X \cdot Y$ as the algebraic intersection number of X and Y.

(2) If M is even-dimensional and if X is a closed oriented submanifold of M such that $2 \cdot \dim(X) = \dim(M)$, then in (1) we can take $Y = X$ and we refer to $X \cdot X \in \mathbb{Z}$ as the algebraic self-intersection number of X

We continue with an analogue of Lemmas 43.2 and 43.3

Lemma 45.1. Let M be an oriented m-dimensional smooth manifold and let $X, Y \subset M$ be two closed oriented submanifolds of M with $\dim(X) + \dim(Y) = \dim(M)$.

(1) The following equality holds:

$$Y \cdot X \;=\; (-1)^{\dim(X)\cdot\dim(Y)} \;\cdot\; X \cdot Y.$$

(2) If we reverse the orientation of precisely one of X, Y or M, then the sign of the algebraic intersection number flips.

Proof.

(1) One might think that this statement is just a special case of Lemma 43.2. But that is not the case: in the definition of the algebraic intersection number in the non-transverse case we apply a smooth isotopy only to the second submanifold. Thus the definition of the algebraic intersection number is not symmetric in X and Y.

We write $k = \dim(X)$ and $l = \dim(Y)$. We denote by $i\colon X \to M$ and $j\colon Y \to M$ the inclusion maps. By the Transversality Theorem 42.4 there exists a smooth isotopy

$G\colon X \times [0,1] \to M$ with $X_0 = i\colon X \to M$ and such that $Y \pitchfork G_1$. By the Isotopy Extension Theorem 36.1 there exists a diffeotopy $H\colon M \times [0,1] \to M$ with $H_0 = \mathrm{id}$ such that for each $(y,t) \in Y \times [0,1]$ we have $H(y,t) = G(y,t)$. Now we see that

$$\begin{array}{lllll}
Y \cdot X & \overset{\text{by definition}}{=} & Y \cdot G_1 & \overset{\text{by Lemma 43.3 and the Smooth Isotopy-Orientation Proposition 34.2}}{=} & H_1^{-1}(Y) \cdot (H_1^{-1} \circ G_1) \\
& & & & = (-1)^{k\cdot l} \cdot X \cdot H_1^{-1}(Y) \\
& & & & \overset{\text{Lemma 43.2}}{=} (-1)^{k\cdot l} \cdot X \cdot H_1^{-1}(Y)
\end{array}$$

$$\begin{array}{lll}
H_1^{-1}(Y) \cdot (H_1^{-1} \circ G_1) & \overset{\text{since } H_1^{-1} \circ G_1 = j}{=} & H_1^{-1}(Y) \cdot X \\
(-1)^{k\cdot l} \cdot X \cdot H_1^{-1}(Y) & = & (-1)^{k\cdot l} \cdot X \cdot H_1^{-1} \\
\overset{\text{by definition}}{=} (-1)^{k\cdot l} \cdot X \cdot H_1^{-1} & = & (-1)^{k\cdot l} \cdot X \cdot Y.
\end{array}$$

by definition of $X \cdot Y$ since the map $Y \times [0,1] \to M,\ (y,t) \mapsto H_t^{-1}(y)$ is a smooth isotopy

(2) This statement follows from the Compatible Orientations Lemma 25.5 (2). ■

Before we can introduce the key definition of this chapter we need to state and prove the following elementary lemma.

Lemma 45.2. Let M be a smooth manifold with $\partial M = \varnothing$.

(1) The diagonal $\Delta_M := \{(x,x) \,|\, x \in M\}$ is a proper submanifold of the smooth manifold $M \times M$.

(2) The diagonal Δ_M is diffeomorphic to M.

Proof. [434] Let M be an n-dimensional smooth manifold with $\partial M = \varnothing$.

(1) Let $(x,x) \in \Delta_M$. We pick a chart $\Phi\colon U \to V$ for $x \in M$. It is straightforward to verify that the map

$$\begin{array}{ccccc}
U \times U & \xrightarrow{\Phi\times\Phi} & V \times V & \to & \{(c,d) \in \mathbb{R}^{2n} \,|\, c+d \in V \text{ and } d \in V\} \\
& & (a,b) & \mapsto & (a-b,b)
\end{array}$$

is a submanifold chart for Δ_M. Since M is by definition Hausdorff we know by Exercise 5.23 that the diagonal Δ_M is a closed subset of $M \times M$. This shows that Δ_M is a proper submanifold of $M \times M$.

(2) We consider the following two maps:

$$\begin{array}{rcl} p\colon \Delta_M & \to & M \\ (x,x) & \mapsto & x \end{array} \qquad \text{and} \qquad \begin{array}{rcl} d\colon M & \to & \Delta_M \\ x & \mapsto & (x,x). \end{array}$$

Evidently these two maps are inverses of one another. Furthermore it follows from the Smooth Manifold Product Proposition 19.31 and the Submanifold Smooth Structure Lemma 19.24 that p and d are smooth. This shows that both maps are diffeomorphisms. ■

Definition. Let M be a closed orientable smooth manifold. We pick an orientation and we consider the product $M \times M$, equipped with the product orientation introduced on page 695, and we consider the submanifold $\Delta_M := \{(x,x) \,|\, x \in M\}$, called the diagonal of M. By Lemma 45.2 (2) we know that Δ_M is orientable. We equip Δ_M with an orientation.

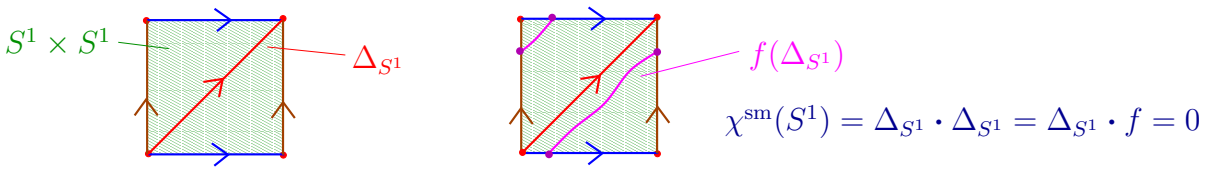
[434] Note that this proof solves Exercise 19.32.

We define the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ of M as follows:

$$\chi^{\mathrm{sm}}(M) := \Delta_M \cdot \Delta_M.$$

Remark. On page 1519 and page 1882 we will define the Euler characteristic $\chi(X)$ of suitable topological spaces X. Furthermore we will see in the Smooth Manifolds-Invariants Proposition 96.6 and alternatively on page 2997 that this more general Euler characteristic is defined for every compact smooth manifold. We will see in the Intersection Number-via-Cup Product Theorem 126.5 and Proposition 128.1, or alternatively in Corollary 129.5 (which we prove twice, once on page 2821 and once on page 3016) that the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ of a closed orientable smooth manifold M agrees with the more general Euler characteristic $\chi(M)$.

Lemma 45.3.



(1) Let M be a closed orientable smooth manifold. The smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ is independent of the choice of the orientation of M and independent of the choice of the orientation of Δ_M.
(2) Let M and N be two closed orientable smooth manifolds. If M and N are diffeomorphic, then $\chi^{\mathrm{sm}}(M) = \chi^{\mathrm{sm}}(N)$.

Proof.

(1) Let M be a closed orientable smooth manifold. The desired statement follows immediately from the following two facts:
- By the Product Orientation Proposition 25.22 (3) we have $(-M)\times(-M) = M\times M$.
- By Lemma 45.1 (2) we have $(-\Delta_M)\cdot(-\Delta_M) = -\Delta_M\cdot(-\Delta_M) = \Delta_M\cdot\Delta_M$.

(2) This statement follows easily from the definitions. ∎

Example. In the figure below we consider $M = S^1$. The diagonal $\Delta_{S^1} \subset S^1 \times S^1$ is the curve shown in the figure. We denote by $\iota\colon \Delta_{S^1} \to S^1 \times S^1$ the inclusion and as in the figure we pick a map $f\colon \Delta_{S^1} \to S^1 \times S^1$ that is smoothly isotopic to ι and which satisfies $\Delta_{S^1} \pitchfork f$. We see that $\Delta_{S^1} \cdot \Delta_{S^1} = \Delta_{S^1} \cdot f = 0$. In fact the next lemma shows that this is not a coincidence.

Lemma 45.4. (Odd-Dimensional Manifold-Euler Characteristic Lemma) The smooth Euler characteristic of any closed orientable *odd-dimensional* smooth manifold is zero.

Remark. In the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7 and the Odd-Dimensional Manifold-Euler Characteristic Corollary 140.5 we will reprove and generalize the Odd-Dimensional Manifold-Euler Characteristic Lemma 45.4.

Proof. Let M be a closed orientable $(2n+1)$-dimensional smooth manifold. By Lemma 45.2 we know that the diagonal Δ_M is also an $(2n+1)$-dimensional smooth manifold. Now we see that

$$\chi^{\mathrm{sm}}(M) \underset{\text{by definition}}{=} \Delta_M \cdot \Delta_M \underset{\text{by Lemma 45.1 (1)}}{=} (-1)^{(2n+1)\cdot(2n+1)} \cdot \Delta_M \cdot \Delta_M = -\Delta_M \cdot \Delta_M \underset{\text{by definition}}{=} -\chi^{\mathrm{sm}}(M).$$

It follows that $\chi^{\mathrm{sm}}(M) = 0$. ∎

It is now natural to try to compute the smooth Euler characteristic of our favorite orientable smooth manifolds. We pose the following question.

Question 45.5.

(1) Let $n \in \mathbb{N}$ be even. What is the smooth Euler characteristic of S^n?
(2) Let $g \in \mathbb{N}$. What is the Euler characteristic of the surface Σ_g of genus g?

To answer Question 45.5 we will have to develop tools for calculating smooth Euler characteristics. In the following sections we will formulate and prove the Smooth Poincaré–Hopf Theorem 45.17 which allows us to compute the smooth Euler characteristic of closed orientable smooth manifolds in terms of "indices" of "non-degenerate" zeros of vector fields. We will then be able to answer Question 45.5 (1) in the Sphere-Euler Characteristic-Proposition 45.19 and we will be able to answer Question 45.5 (2) in the Surface-Euler Characteristic Proposition 45.20.

45.2. **Zeros of vector fields.** As on several occasions we adopt for the remainder of this chapter the following popular convention.

Convention. We will use the natural isomorphism from the Tangent Space-Isomorphism Proposition 23.16 to go back and forth between the physical tangent space $\widetilde{\mathrm{T}}_P M$ and the abstract tangent space $\mathrm{T}_P M$ of a smooth submanifold M of some $\mathbb{R}^n$.

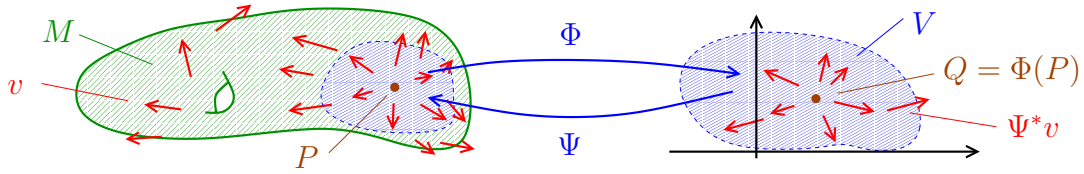
Recall that on page 639 we introduced the notion of a smooth vector field on a smooth manifold and recall the following definition from the Vector Field-Pullback Lemma 23.21.

Notation. Let $f\colon M \to N$ be a local diffeomorphism between two smooth manifolds M and N and let w be a vector field on N. We denote by f^*w the vector field on M which assigns to each $P \in M$ the tangent vector $(\mathrm{D}f_P)^{-1}(w(f(P)))$.[435]

We continue with a new aspect of vector fields.

Definition. Let M be a smooth manifold and let v be a smooth vector field on M. Let $P \in M \setminus \partial M$ be a zero of v. We pick a chart $\Phi\colon U \to V$. We set $Q := \Phi(P)$ and we write $\Psi := \Phi^{-1}$. We consider the map

$$\begin{aligned} \Psi^*v\colon V &\to \mathbb{R}^n \\ x &\mapsto (\Psi^*v)(x) = \underbrace{\mathrm{D}\Phi_{\Psi(x)}(v(\Psi(x)))}_{\in \mathrm{T}_x\mathbb{R}^n = \widetilde{\mathrm{T}}_x\mathbb{R}^n = \mathbb{R}^n}. \end{aligned}$$



(1) If $\mathrm{D}(\Psi^*v)_Q$ is an invertible matrix, then we say that the zero is non-degenerate. Otherwise we call the zero degenerate.

[435] We will often use that by the Vector Field-Pullback Lemma 23.21 we know that if w is a smooth vector field, then f^*w is also smooth.

(2) If the zero P is non-degenerate, then we define

$$\operatorname{index}(v,P) := \begin{cases} +1, & \text{if } \det(\mathrm{D}(\Psi^* v)_Q) > 0, \\ -1, & \text{if } \det(\mathrm{D}(\Psi^* v)_Q) < 0. \end{cases}$$

In Lemma 45.6 we will see that these notions do not depend on the choice of the chart Φ.

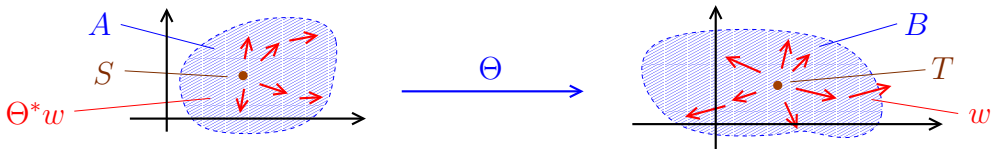
Lemma 45.6. The notions introduced in the previous definition do not depend on the choice of the chart Φ.

In the proof of Lemma 45.6 we will need the following, potentially slightly confusing, little lemma.

Auxiliary Lemma 45.7. Let $A \subset \mathbb{R}^m$ be an open subset and let $\Xi\colon A \to \mathrm{M}(n \times k, \mathbb{R})$ and $u\colon A \to \mathbb{R}^k$ be smooth maps. Let $S \in A$. If $u(S) = 0$, then

$$\mathrm{D}(\underbrace{x \mapsto \Xi(x) \cdot u(x)}_{\text{map } A \to \mathbb{R}^n})_S \;=\; \Xi(S) \cdot \mathrm{D}u_S \quad \in \mathrm{M}(n \times m, \mathbb{R}).$$

Proof of Lemma 45.7. The lemma follows immediately from the Product Rule applied to each entry and the fact that $u(S) = 0$. ∎



Proof of Lemma 45.6. Let M be an n-dimensional smooth manifold, let v be a smooth vector field on M and let $P \in M \setminus \partial M$ be a zero of v. We need to show that if we have two different charts $\Phi\colon U \to V$ and $\widetilde{\Phi}\colon \widetilde{U} \to \widetilde{V}$ around P, then we end up with the same notion of degeneracy and index.

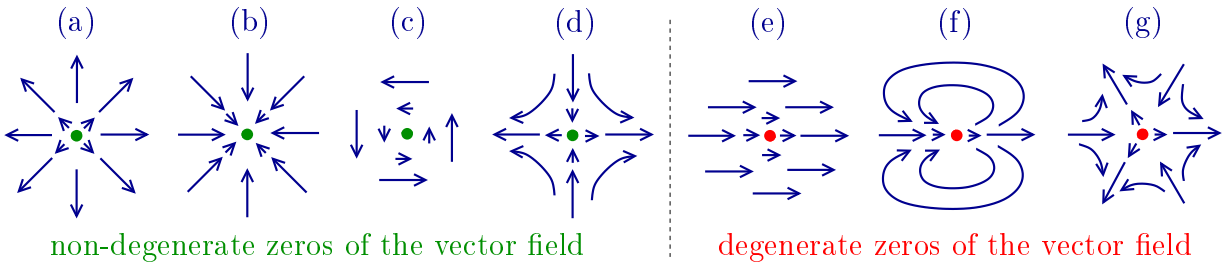
We set $A := \Phi(U \cap \widetilde{U})$, $B = \widetilde{\Phi}(U \cap \widetilde{U})$ and we denote by $\Theta := \widetilde{\Phi} \circ \Phi^{-1}\colon A \to B$ the transition map between the two charts. It follows easily from Lemma 35.5 that we only have to prove the following claim.

Claim. Let $\Theta\colon A \to B$ be a diffeomorphism between two open subsets of some $\mathbb{R}^n$. Let $w\colon B \to \mathbb{R}^n$ be a smooth vector field on B with a zero at some point $T \in B$. We set $S := \Theta^{-1}(T) \in A$. We consider the maps

$$\begin{array}{rccc} \Theta^* w\colon & A & \to & \mathbb{R}^n \\ & x & \mapsto & (\Theta^* w)(x) \end{array} \qquad \text{and} \qquad \begin{array}{rccc} w\colon & B & \to & \mathbb{R}^n \\ & y & \mapsto & w(y). \end{array}$$

Then $\mathrm{D}(\Theta^* w)_S$ is invertible if and only if $\mathrm{D}w_T$ is invertible. Furthermore $\det(\mathrm{D}(\Theta^* w)_S) > 0$ if and only if $\det(\mathrm{D}w_T) > 0$.

Proof. Note that



$$\begin{array}{lll} & \text{by definition and the Differential-equals-Differential Lemma 23.4} & \\ & \downarrow & \\ \mathrm{D}(x \mapsto (\Theta^* w(x)))_S & = & \mathrm{D}\big(x \mapsto (\mathrm{D}\Theta_x)^{-1} \cdot (w \circ \Theta)(x)\big)_S \\ & = & (\mathrm{D}\Theta_S)^{-1} \cdot \mathrm{D}(w \circ \Theta)_S \quad = \quad (\mathrm{D}\Theta_S)^{-1} \cdot \mathrm{D}w_T \circ \mathrm{D}\Theta_S. \\ & \uparrow & \uparrow \\ & \text{by Lemma 45.7 and since } (w \circ \Theta)(S) = 0 & \text{by the Chain Rule and since } \Theta(S) = T \end{array}$$

This shows that $\mathrm{D}(\Theta^* w)_S$ is invertible if and only if $\mathrm{D}w_T$ is invertible. Furthermore we see that $\det(\mathrm{D}(\Theta^* w)_S) > 0$ if and only if $\det(\mathrm{D}w_T) > 0$. ■

Remark. On page 2818 we will introduce a more general notion of an index of a zero of a vector field which is defined also for degenerate zeros of vector fields. It follows from Lemma 76.15 that the two definitions of the index agree, if both are defined.

Example. We consider the vector fields on $\mathbb{R}^2 = \mathbb{C}$ with isolated zero at the origin that are shown in the figure below. In the following we use the identity chart $\Phi = \mathrm{id}$ to determine the various indices. We obtain the following table:

	(a)	(b)	(c)	(d)	(e)	(f)	(g)
vector field v at $(x,y)=z$	(x,y)	$(-x,-y)$	$(-y,x)$	$(x,-y)$	$(x^2+y^2,0)$	z^2	z^{-2}
$\mathrm{D}v_{(0,0)}$	$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$	$\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}$	$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$	$\begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$	$\begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$	$\begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$
	non-degenerate zero				degenerate zero		
index	1	1	1	-1	not defined		

We state our last example of indices of zeros of vector fields as a lemma.

Lemma 45.8. Given any $n \in \mathbb{N}_0$ there exists a smooth vector field v on S^n with the following properties:

(1) The vector field has precisely two zeros, namely at the South Pole $S = (0, \ldots, 0, -1)$ and at the North Pole $N = (0, \ldots, 0, 1)$.
(2) The two zeros are non-degenerate and the indices are given by $\mathrm{index}(v, S) = 1$ and $\mathrm{index}(v, N) = (-1)^n$.

Proof. Statement (1) is taken care of by the following claim.

Claim. We think of S^n as a subspace of $\mathbb{R}^n \times \mathbb{R}$. The map

$$\begin{array}{rcl} v\colon S^n & \to & \mathbb{R}^{n+1} \\ \underbrace{(x,y)}_{x\in\mathbb{R}^n,\, y\in\mathbb{R}} & \mapsto & (x\cdot(-y), \|x\|^2) \end{array}$$

defines a smooth vector field on S^n with precisely two zeros, namely at S and N.

Proof. It follows from $\|x\|^2 = x_1^2 + \cdots + x_n^2$ that v is a smooth map. It is clear that for $(x,y) \in S^n \subset \mathbb{R}^n \times \mathbb{R}$ we have $v(x,y) = 0$ if and only if $x = 0$. In particular N and S are the only two zeros. Next note that for each $(x,y) \in S^n$ we have

$$\langle (x,y), v(x,y)\rangle \;=\; \langle (x,y), (x\cdot(-y), \|x\|^2\rangle \;=\; -\langle x,x\rangle \cdot y + y\cdot\|x\|^2 \;=\; 0.$$

Thus it follows from Lemma 23.1 that $v(x,y) \in \widetilde{\mathrm{T}}_{(x,y)}S^n$. This shows that v defines indeed a smooth vector field on the smooth manifold S^n. ⊞

It remains to prove Statement (2). For $\epsilon = \pm 1$ we consider the zero $P_\epsilon = (0,\dots,0,\epsilon)$ of our vector field v. We consider the chart

$$\begin{array}{rcl} \Phi_\epsilon\colon U := S^n_{>0} = \{(x,y) \in S^n \subset \mathbb{R}^n \times \mathbb{R} \,|\, y\cdot\epsilon > 0\} & \to & B^n \\ (x,y) & \mapsto & x. \end{array}$$

The inverse of the chart is given by $\Psi_\epsilon(x) = (x, \epsilon\cdot\sqrt{1-\|x\|^2})$. A straightforward calculation shows that $\Psi_\epsilon^* v$ is given by

$$\begin{array}{rcl} \Psi_\epsilon^* v\colon B^n & \to & \mathbb{R}^n \\ x & \mapsto & -\epsilon\cdot x\cdot\sqrt{1-\|x\|^2}. \end{array}$$

An elementary calculation shows that $\mathrm{D}(\Psi_\epsilon^* v)_0 = (-\epsilon)\cdot \mathrm{id}$. This shows that the zero of v at P_ϵ is non-degenerate and that $\mathrm{index}(v, P_\epsilon) = (-\epsilon)^n$. ■

Lemma 45.9. Let M be a smooth manifold and let v be a smooth vector field on M.

(1) Every non-degenerate zero of v is an isolated point in the set of zeros of v.
(2) If M is compact and if all zeros of v are non-degenerate, then v has only finitely many zeros.

Proof.

(1) Using a chart it is clear that we only need to deal with the case that M is an open subset of some $\mathbb{R}^n$ and that $v\colon M \to \mathbb{R}^n$ is a smooth vector field with a zero at $x = 0$. In this setting the statement follows easily from the Inverse Function Theorem 19.12.
(2) This statement follows from (1) together with the Compact-Closed Lemma 1.21, the Compact-Discrete Lemma 1.22 and the fact that smooth manifolds are by definition Hausdorff. ■

The above discussion motivates the following question.

Question 45.10. Does every closed smooth manifold admit a smooth vector field such that all zeros are non-degenerate?

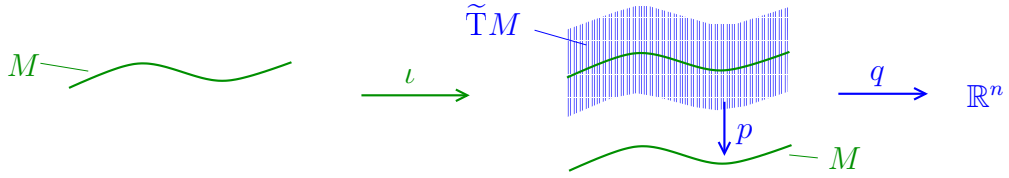
To answer Question 45.10 we will develop some more general theory in the following section. We will then be able to answer the question in Proposition 45.15.

45.3. **The total tangent space and vector fields.** In this section we will introduce the total tangent space and we will prove several statements that relate the total tangent space with vector fields. This discussion might initially appear tangential to the topics so far. But in fact we will be so successful in this section, that afterwards the proofs of the main result of this chapter, namely the Smooth Poincaré–Hopf Theorem 45.17, will be a breeze.

We start out with the following new notation.

Notation.

(1) Let M be a smooth submanifold of $\mathbb{R}^n$. We define the total tangent space



$$\widetilde{\mathrm{T}}M \;:=\; \{(x,v) \in \mathbb{R}^n \times \mathbb{R}^n \,|\, x \in M \text{ and } v \in \widetilde{\mathrm{T}}_x M\}.$$

(2) Let M be a smooth submanifold of $\mathbb{R}^m$ and let N be an smooth submanifold of $\mathbb{R}^n$. Given any smooth map $f\colon M \to N$ we obtain an induced map

$$\begin{array}{rccc} f_*\colon & \widetilde{\mathrm{T}}M & \to & \widetilde{\mathrm{T}}N \\ & (x,v) & \mapsto & (f(x), \mathrm{D}f_x(v)). \end{array}$$

(3) We consider the maps

$$\begin{array}{rccc} p\colon & \widetilde{\mathrm{T}}M & \to & M \\ & (x,y) & \mapsto & x \end{array} \qquad \begin{array}{rccc} q\colon & \widetilde{\mathrm{T}}M & \to & \mathbb{R}^n \\ & (x,y) & \mapsto & y \end{array} \qquad \text{and} \qquad \begin{array}{rccc} \iota\colon & M & \to & \widetilde{\mathrm{T}}M \\ & x & \mapsto & (x,0). \end{array}$$

Remark. Let M be a smooth submanifold of $\mathbb{R}^n$. The total tangent space $\widetilde{\mathrm{T}}M$ *together* with the map $p\colon \widetilde{\mathrm{T}}M \to M$ is called the *tangent bundle* of M. The tangent bundle will play a significant role later on.

Lemma 45.11. Let $k \in \mathbb{N}$.

(1) Let M be a k-dimensional smooth submanifold of $\mathbb{R}^n$.
  (a) The subset $\widetilde{\mathrm{T}}M$ is a $2k$-dimensional smooth submanifold of $\mathbb{R}^n \times \mathbb{R}^n$.
  (b) For each $(x,v) \in \widetilde{\mathrm{T}}M$ we have $\widetilde{\mathrm{T}}_{(x,v)}\widetilde{\mathrm{T}}M = \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M \subset \mathbb{R}^n \times \mathbb{R}^n$.
  (c) If M is oriented, then there exists a unique orientation on $\widetilde{\mathrm{T}}M$ such that for each $(x,v) \in \widetilde{\mathrm{T}}M$ the equality $\widetilde{\mathrm{T}}_{(x,v)}\widetilde{\mathrm{T}}M = \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M \subset \mathbb{R}^n \times \mathbb{R}^n$ is an equality of oriented vector spaces.

(2) Let M be a smooth submanifold of $\mathbb{R}^m$ and let N be a smooth submanifold of $\mathbb{R}^n$. Furthermore let $f\colon M \to N$ be a smooth map.
  (a) The map $f_*\colon \widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}N$ is smooth.
  (b) If f is an orientation-preserving local diffeomorphism, then so is $f_*\colon \widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}N$.

(3) The construction in (1a) and the maps in (2a) define a covariant functor from the category $\mathcal{SmMfd}_{\mathbb{R}^n}$ of smooth submanifolds of some $\mathbb{R}^n$, which we introduced on page 626, to itself.

Proof.

(1) (a) Recall that we denote by $p\colon \widetilde{\mathrm{T}}M \to M$ the projection. Let $\Phi\colon U \to V$ be a submanifold chart for M. One can easily verify that

$$\begin{aligned} p^{-1}(U) = U \times \mathbb{R}^n &\to V \times \mathbb{R}^n \\ (x, v) &\mapsto (\Phi(x), \mathrm{D}\Phi_x(v)) \end{aligned}$$

is, after a permutation of coordinates, a submanifold chart for $\widetilde{\mathrm{T}}M$. Thus we have shown that $\widetilde{\mathrm{T}}M \to M$ is a $2k$-dimensional smooth submanifold of $\mathbb{R}^n \times \mathbb{R}^n$.

(b) Let $(x, v) \in \widetilde{\mathrm{T}}M$. One can easily verify that $\widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M \subset \widetilde{\mathrm{T}}_{(x,v)}\widetilde{\mathrm{T}}M$. But since both are $2k$-dimensional vector spaces we actually have equality.

(c) We leave it to the reader to verify that this way we get an orientation for $\widetilde{\mathrm{T}}M$.

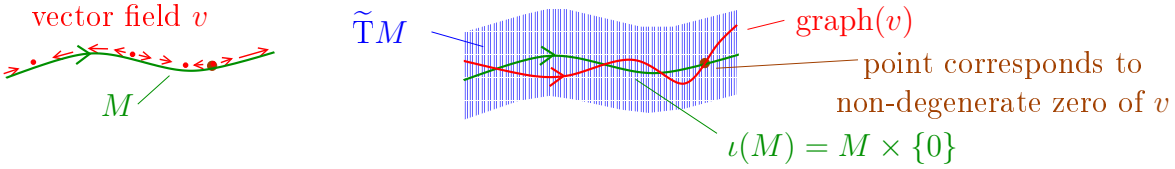
(2) We leave the verification of this statement to the reader.

(3) This statement follows easily from the definitions. ■

Notation. Let M be a k-dimensional smooth submanifold of $\mathbb{R}^n$. Given a smooth vector field $v\colon M \to \mathbb{R}^n$ on M we consider the graph

$$\operatorname{graph}(v) \;:=\; \{(x, v(x)) \,|\, x \in M\} \;\subset \widetilde{\mathrm{T}}M.$$

As on page 526 one can easily verify that $\operatorname{graph}(v)$ is a k-dimensional smooth submanifold of $\widetilde{\mathrm{T}}M$ such that the map $p\colon \operatorname{graph}(v) \to M$, $(x, y) \mapsto x$, is a diffeomorphism. If M is oriented, then we equip $\operatorname{graph}(v)$ with the corresponding orientation.[436]



Proposition 45.12. Let M be a smooth submanifold of $\mathbb{R}^n$ with empty boundary and let v be a smooth vector field on M. The following statements hold:

(0) We have $(x, y) \in \iota(M) \cap \operatorname{graph}(v)$ if and only if $x \in M$, $y = 0$ and $v(x) = 0$.

(1) All zeros of the vector field v are non-degenerate if and only if the two submanifolds $\iota(M) = M \times \{0\}$ and $\operatorname{graph}(v)$ intersect transversally in $\widetilde{\mathrm{T}}M$, i.e. if $\iota(M) \pitchfork \operatorname{graph}(v)$.

(2) If x is non-degenerate zero of v, then

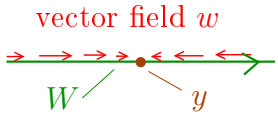
$$\operatorname{index}(v, x) \;=\; \text{sign of the intersection point } (x, 0) \text{ of } \iota(M) \text{ and } \operatorname{graph}(v).$$

We first prove Proposition 45.12 for open subsets of $\mathbb{R}^k$. This is almost precisely the content of the following lemma.

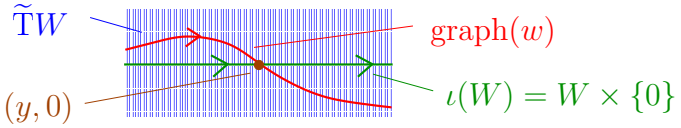
Lemma 45.13. Let W be an open subset of $\mathbb{R}^k$ and let $w\colon W \to \mathbb{R}^k$ be a smooth vector field on W. The following statements hold:

(1) Let $y \in W$ be a zero of the vector field w. The zero y is non-degenerate if and only if the submanifolds $\iota(W) = W \times \{0\}$ and $\operatorname{graph}(w)$ of in $\widetilde{\mathrm{T}}W = W \times \mathbb{R}^k$ intersect transversally in $(y, 0)$.

[436] If v is the zero vector field, then $\operatorname{graph}(v) = M \times \{0\} = \iota(M)$, and we see that $\iota(M)$ is also an (oriented) k-dimensional smooth submanifold of $\widetilde{\mathrm{T}}M$.



(2) If $y \in W$ is a non-degenerate zero of w, then



$$\text{index}(w, y) \;=\; \text{sign of the intersection point } (y,0) \text{ of } \iota(W) \text{ and } \text{graph}(w).$$

Proof of Lemma 45.13. Let W be an open subset of $\mathbb{R}^k$, let $w\colon W \to \mathbb{R}^k$ be a smooth vector field on W and let $y \in W$ be a point with $w(y) = 0$. Evidently $(y, 0)$ is an intersection point of $\iota(W) = W \times \{0\}$ and $\text{graph}(w)$. For the definition of a non-degenerate zero and the index of a non-degenerate zero we need to pick a chart. But since W is already an open subset of $\mathbb{R}^k$ we might as well use the identity chart. Next note that

$$\begin{aligned}\widetilde{\mathrm{T}}_{(y,0)}\iota(W) + \widetilde{\mathrm{T}}_{(y,0)}\,\text{graph}(w) \;&=\; \text{im}\begin{pmatrix} \mathbb{R}^k \to \mathbb{R}^k \times \mathbb{R}^k \\ a \mapsto \begin{pmatrix} a \\ 0 \end{pmatrix} \end{pmatrix} + \text{im}\begin{pmatrix} \mathbb{R}^k \to \mathbb{R}^k \times \mathbb{R}^k \\ a \mapsto \begin{pmatrix} a \\ \mathrm{D}w_{(y,0)} \cdot a \end{pmatrix} \end{pmatrix} \\ &=\; \begin{pmatrix} \mathrm{id} & \mathrm{id} \\ 0 & \mathrm{D}w_{(y,0)} \end{pmatrix} \begin{pmatrix} \mathbb{R}^k \\ \mathbb{R}^k \end{pmatrix}.\end{aligned}$$

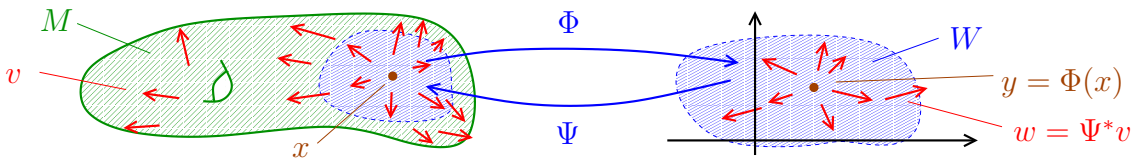
We see that $\widetilde{\mathrm{T}}_{(y,0)}\iota(W) + \widetilde{\mathrm{T}}_{(y,0)}\,\text{graph}(w) = \mathbb{R}^{2k} = \widetilde{\mathrm{T}}_{(y,0)}\widetilde{\mathrm{T}}W$ if and only if $\mathrm{D}w_{(y,0)}\colon \mathbb{R}^k \to \mathbb{R}^k$ is an isomorphism. This observation, together with the definitions on pages 968 and 1021 concludes the proof of Statement (1).

Finally Statement (2) follows from the following little calculation:

$$\begin{array}{ccccccc} \text{sign of the intersection point} \\ (y,0) \text{ of } \iota(W) \text{ and } \text{graph}(w) \end{array} \;\underset{\uparrow}{=}\; \det\begin{pmatrix} \mathrm{id} & \mathrm{id} \\ 0 & \mathrm{D}w_{(y,0)} \end{pmatrix} \;=\; \det(\mathrm{D}w_{(y,0)}) \;\underset{\uparrow}{=}\; \text{index}(w, y).$$

by the above discussion and the definition on page 989 — see definition on page 1021 ■

Proof of Proposition 45.12. Let M be a k-dimensional smooth submanifold of $\mathbb{R}^n$ with empty boundary and let v be a smooth vector field on M. Statement (0) follows immediately from the definitions.



Let $x \in M$ be a zero of the vector field. We pick a chart $\Phi\colon V \to W$ around x. We set $y := \Phi(x)$ and we set $\Psi := \Phi^{-1}$. We consider the vector field $w := \Psi^* v$. The desired statements follow from Lemma 45.13 and the following claim.

Claim.

(1) The point $y \in W$ is a zero of the vector field w.
(2) $x \in M$ is non-degenerate if and only if $y \in W$ is non-degenerate.
(3) $\text{index}(v, x) = \text{index}(w, y)$.
(4) $(x, 0)$ is a transverse intersection point of $\iota(M)$ and $\text{graph}(v)$ if and only if $(y, 0)$ is a transverse intersection point of $\iota(W)$ and $\text{graph}(w)$.
(5) The sign of the intersection point $(x, 0)$ equals the sign of the intersection point $(y, 0)$.

Proof.

(1) This statement is trivial.
(2),(3) These two statements hold by the definitions of non-degeneracy and of the index on page 1021.

(4),(5) We denote by $i\colon V \to M$ the inclusion. We consider the following diagram:

$$\begin{array}{ccccc}
M & \xleftarrow{\ i\ } & V & \longrightarrow & W \\
\downarrow{\scriptstyle \iota} & & \downarrow{\scriptstyle \iota} & & \downarrow{\scriptstyle \iota} \\
\widetilde{\mathrm{T}}M & \xleftarrow{\ i_*\ } & \widetilde{\mathrm{T}}V & \xrightarrow{\ \Phi_*\ } & \widetilde{\mathrm{T}}W \\
\uparrow & & \uparrow & & \uparrow \\
\mathrm{graph}(v\colon M \to \mathbb{R}^n) & \xleftarrow{\ i_*\ } & \mathrm{graph}(v\colon V \to \mathbb{R}^n) & \xrightarrow{\ \Phi_*\ } & \mathrm{graph}(w\colon W \to \mathbb{R}^k)
\end{array}$$

We make the following observations:

(a) It follows easily from the definitions that $i_*\colon \widetilde{\mathrm{T}}V \to \widetilde{\mathrm{T}}M$ and $\Phi_*\colon \widetilde{\mathrm{T}}V \to \widetilde{\mathrm{T}}W$ restrict to local diffeomorphisms $\mathrm{graph}(v\colon V \to \mathbb{R}^n) \to \mathrm{graph}(v\colon M \to \mathbb{R}^n)$ and $\mathrm{graph}(v\colon V \to \mathbb{R}^n) \to \mathrm{graph}(w\colon W \to \mathbb{R}^k)$.

(b) It follows immediately from the definitions that the diagram commutes and that the horizontal maps are orientation-preserving local diffeomorphisms.

The desired Statements (4) and (5) follow immediately from this discussion. ■

Lemma 45.14. Let M be a closed smooth submanifold of $\mathbb{R}^n$. There exists a smooth vector field v on M such that $\iota(M) \pitchfork \mathrm{graph}(v)$.

Proof. Let M be a closed smooth submanifold of $\mathbb{R}^n$. As before we consider the natural projection $p\colon \widetilde{\mathrm{T}}M \to M$.

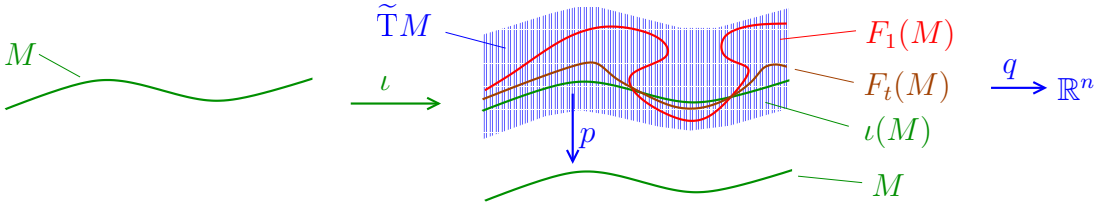
Claim. There exists a smooth embedding $g\colon M \to \widetilde{\mathrm{T}}M$ such that $\iota(M) \pitchfork g$ and such that $p \circ g = \mathrm{id}_M$ in $\widetilde{\mathrm{T}}M$.

Proof. Note that by the Transversality Theorem 42.4 there exists a smooth homotopy $F\colon M \times [0,1] \to \widetilde{\mathrm{T}}M$ with $F_0 = \iota$ such that

$$T \ := \ \{t \in [0,1] \,|\, \text{the map } F_t\colon M \to \widetilde{\mathrm{T}}M \text{ is transverse to } \iota(M) \text{ in } \widetilde{\mathrm{T}}M\}$$

has full measure in $[0,1]$. By the Measure-Zero Properties Proposition 30.2 this means that T is dense in $[0,1]$. Next we consider the smooth homotopy

$$\begin{array}{rcl} H\colon M \times [0,1] & \to & M \\ (x,t) & \mapsto & p(F(x,t)). \end{array}$$



It follows from $H_0 = \mathrm{id}$, the fact that M is closed, the Deform Smooth Embedding Proposition 33.6 (2) and the fact that T is dense in $[0,1]$ that there exists a $t \in T$ such that H_t is a diffeomorphism. By Lemma 45.11 the diffeomorphism $H_t^{-1}\colon M \to M$ induces a diffeomorphism $(H_t^{-1})_*\colon \widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}M$. Finally we set $g := (H_t^{-1})_* \circ F_t\colon M \to \widetilde{\mathrm{T}}M$. We claim that g has the desired properties. This claim follows from the following two observations:

- It follows immediately from the definitions that $(H_t^{-1})_*(\iota(M)) = \iota(M)$. Thus the fact that $\iota(M) \pitchfork F_t$ implies that $\iota(M) \pitchfork (H_t^{-1})_* \circ F_t$.

- We have the following equalities of maps $M \to M$:

$$p \circ g \;=\; p \circ ((H_t^{-1})_* \circ F_t) \;=\; (p \circ (H_t^{-1})_*) \circ F_t \;\overset{\text{by definition of } (H_t^{-1})_* \colon \widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}M}{\downarrow =}\; (H_t^{-1} \circ p) \circ F_t$$
$$= \; H_t^{-1} \circ \underbrace{(p \circ F_t)}_{=H_t} \;=\; \mathrm{id}\,.$$

⊞

Finally we study the vector field

$$\begin{aligned} v \colon M &\to \mathbb{R}^n \\ x &\mapsto \underbrace{q(g(x))}_{\in \widetilde{\mathrm{T}}_x M}. \end{aligned}$$

Since $p \circ g = \mathrm{id}_M$ we see that $\mathrm{graph}(v) = g(M)$. Since $\iota(M) \pitchfork g$ and since $g \colon M \to \widetilde{\mathrm{T}}M$ is a smooth embedding it follows from the remark on page 968 that $\iota(M) \pitchfork \mathrm{graph}(v)$. ■

Now we can prove the following proposition, which gives an affirmative answer to Question 45.10.

Proposition 45.15. (Non-Degenerate Vector Field Existence Proposition) Every closed smooth manifold admits a vector field v such that each zero of v is non-degenerate.

Remark. In Proposition 129.4, which we will prove twice on page 2821 and 2983, we will give an alternative proof of the Non-Degenerate Vector Field Existence Proposition 45.15.

Proof. Let M be a closed smooth manifold. By the Euclidean Embedding Theorem 27.1 it suffices to deal with the case that M is a k-dimensional smooth submanifold of some $\mathbb{R}^n$ and vector fields that are defined in terms of the physical tangent spaces. It follows from Lemma 45.14 that there exists a smooth vector field v on M such that $\iota(M) \pitchfork \mathrm{graph}(v)$ in $\widetilde{\mathrm{T}}M$. By Proposition 45.12 this implies that v is a vector field such that each zero of v is non-degenerate. ■

45.4. The total tangent space and the diagonal.

Proposition 45.16. (Total Tangent Space-Diagonal Embedding Proposition) Let M be a closed smooth submanifold of $\mathbb{R}^n$. There exists a smooth embedding

$$f \colon \widetilde{\mathrm{T}}M \;\to\; M \times M$$

such that for each $x \in M$ we have $f(x,0) = (x,x)$. If M is oriented, then this smooth embedding can be chosen to be orientation-preserving.

The proof of Proposition 45.16 rests on the following tricky theorem from an earlier chapter.

Theorem 21.13. (Neighborhood Smooth Embedding Theorem) Let $b \colon X \to Y$ be a map between smooth manifolds. Furthermore let $C \subset X$ be a compact subset such that the map $b \colon C \to Y$ is an embedding. If b is a local diffeomorphism at each $P \in C$, then there exists an open neighborhood U of C such that the restriction of b to U is a smooth embedding.

Proof of Proposition 45.16. Let M be a closed k-dimensional smooth submanifold of $\mathbb{R}^n$. Given $\sigma > 0$ we write

$$\widetilde{\mathrm{T}}M(\sigma) \;:=\; \{(x,v) \in \widetilde{\mathrm{T}}M \,|\, \|v\| < \sigma\}.$$

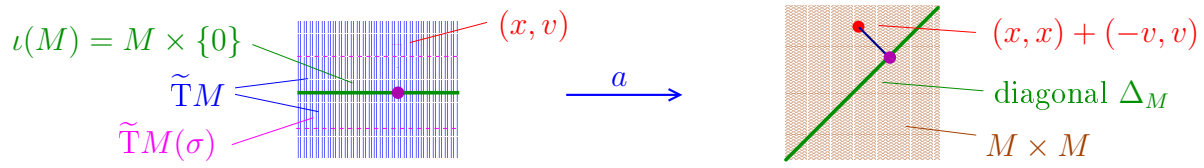
We prove a few basic facts about $\widetilde{\mathrm{T}}M(\sigma)$.

Claim 1.

(1) For every $\sigma > 0$ the above set $\widetilde{\mathrm{T}}M(\sigma)$ is an open subset of $\widetilde{\mathrm{T}}M$. Thus we can view $\widetilde{\mathrm{T}}M(\sigma)$ as an (oriented) smooth manifold.
(2) Given any open neighborhood W of $M \times \{0\} \subset \widetilde{\mathrm{T}}M$ there exists a $\sigma > 0$ such that $\widetilde{\mathrm{T}}M(\sigma) \subset W$.
(3) For every $\sigma > 0$ there exists a diffeomorphism $\widetilde{\mathrm{T}}M(\sigma) \to \widetilde{\mathrm{T}}M$ which is the identity on the common subset $M \times \{0\}$. If M is oriented, then the diffeomorphism can be chosen to be orientation-preserving.

Proof.

(1) This statement follows easily from the definition of the product topology on $\mathbb{R}^n \times \mathbb{R}^n$ and the definition of the subspace topology on $\widetilde{\mathrm{T}}M$.
(2) Since W is an open neighborhood of $M \times \{0\} \subset \widetilde{\mathrm{T}}M(\sigma)$ we know, by the definition of the product topology on $\mathbb{R}^n \times \mathbb{R}^n$ and by definition of the subspace topology on $\widetilde{\mathrm{T}}M$, that for each $P \in M$ there exists an open neighborhood U_P of $P \in M$ and a $\sigma_P > 0$ such that $\{(x,v) \in \widetilde{\mathrm{T}}M \,|\, x \in U_P \text{ and } \|v\| < \sigma_P\} \subset W$. Since M is compact there exist $P_1, \ldots, P_m \in M$ with $M = U_{P_1} \cup \cdots \cup U_{P_m}$. It is clear that $\sigma := \min\{\sigma_{P_1}, \ldots, \sigma_{P_m}\}$ has the desired properties.
(3) Using the Smooth Transition Function Lemma 19.4 one can easily show that there exists an orientation-preserving diffeomorphism $\chi\colon [0,\sigma) \to \mathbb{R}_{\geq 0}$ that is the identity on a neighborhood of 0. We consider the map



$$\begin{array}{rcl} g\colon \widetilde{\mathrm{T}}M(\sigma) & \to & \widetilde{\mathrm{T}}M \\ (x,v) & \mapsto & \begin{cases} (x,0), & \text{if } v = 0, \\ (x, \frac{v}{\|v\|} \cdot \chi(\|v\|)), & \text{if } v \neq 0. \end{cases} \end{array}$$

Note that g is the identity on a neighborhood of $M \times \{0\}$. Using the Smooth Pasting Proposition 19.3 one can now show that g is smooth. Using the inverse of the diffeomorphism χ one can easily write down a smooth inverse to the map g, thus we see that g is a diffeomorphism. If M is oriented, then g is evidently orientation-preserving. ⊞

We consider the map[437]

$$\begin{array}{rcl} a\colon \widetilde{\mathrm{T}}M & \to & \mathbb{R}^n \times \mathbb{R}^n \\ (x,v) & \mapsto & (x,x) + (-v,v). \end{array}$$

[437]There are many choices for a, for example $a(x,v) = (x,x) + (0,v)$ would also work. We picked the given map for subjective aesthetic reasons.

Claim 2. For each $x \in M$ the map

$$\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \mathbb{R}^n \times \mathbb{R}^n$$

restricts to an isomorphism

$$\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M.$$

If M is oriented, then this isomorphism is orientation-preserving.

Proof. Recall that by Lemma 45.11 we know that $\widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M = \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$. Since a is a linear map it follows almost immediately that the map $\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \mathbb{R}^n \times \mathbb{R}^n$ is given by the map

$$\begin{array}{rcl} \mathrm{D}a_{(x,0)} \colon \overbrace{\widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M}^{\subset \mathbb{R}^n \times \mathbb{R}^n} & \to & \mathbb{R}^n \times \mathbb{R}^n \\ \begin{pmatrix} u \\ v \end{pmatrix} & \to & \begin{pmatrix} u \\ u \end{pmatrix} + \begin{pmatrix} -v \\ v \end{pmatrix}. \end{array}$$

Thus we see that the image of $\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \mathbb{R}^n \times \mathbb{R}^n$ lies in $\widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$. Next we pick a basis for $\widetilde{\mathrm{T}}_x M$ and we equip $\widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$ with the obvious corresponding basis. It follows from the above discussion, that with this choice of a basis, the map $\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$ is represented by the matrix $\begin{pmatrix} \mathrm{id} & -\mathrm{id} \\ \mathrm{id} & \mathrm{id} \end{pmatrix}$. Therefore we see that the map $\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$ is a monomorphism. Since both vector spaces are $2k$-dimensional we see that $\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$ is in fact an isomorphism. Furthermore, if M is oriented, then we see that, with the appropriate orientations, the map $\mathrm{D}a_{(x,0)} \colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_x M \times \widetilde{\mathrm{T}}_x M$ is also orientation-preserving. ⊞

By the Neighborhood Projection Theorem 28.1 there exists an open neighborhood Z of $M \times M \subset \mathbb{R}^n \times \mathbb{R}^n$ and a smooth retraction $\pi \colon Z \to M \times M$. Note that $a^{-1}(Z)$ is an open neighborhood of $M \times \{0\} \subset \widetilde{\mathrm{T}}M$. It follows from Claim 1 (b) that there exists a $\mu > 0$ such that $\widetilde{\mathrm{T}}M(\mu) \subset a^{-1}(Z)$. By Claim 1 (c) and Claim 2 it now suffices to prove the following claim.

Claim 3. There exists a $\nu \in (0, \mu)$ such that the following map is a smooth embedding:

$$\begin{array}{rcl} b \colon \widetilde{\mathrm{T}}M(\nu) & \to & M \times M \\ (x, v) & \mapsto & \pi(a(x, v)). \end{array}$$

Proof. By the choice of μ it makes sense to consider the map

$$\begin{array}{rcl} b \colon \widetilde{\mathrm{T}}M(\mu) & \to & M \times M \\ (x, v) & \mapsto & \pi(a(x, v)). \end{array}$$

We make the following two observations:

(1) Since $\pi\colon Z \to M$ is a retraction we see that the restriction of b to the closed subset $M \times \{0\}$ of $\widetilde{\mathrm{T}}M(\mu)$ is given by the map $x \mapsto (x, x)$. It follows from the Compact-Hausdorff Proposition 2.17 that the map $b\colon M \times \{0\} \to \widetilde{\mathrm{T}}M(\mu)$ is an embedding.

(2) Let $(x, 0) \in M \times \{0\}$ be arbitrary. By Claim 2 we know that we get an isomorphism $\mathrm{D}a_{(x,0)}\colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_xM \times \widetilde{\mathrm{T}}_xM$. Since $\pi\colon Z \to M \times M$ is a retraction we know that the restriction of $\mathrm{D}\pi_{(x,x)}$ to $\widetilde{\mathrm{T}}_{(x,x)}(M \times M) = \widetilde{\mathrm{T}}_xM \times \widetilde{\mathrm{T}}_xM$ is the identity. In summary we see that the map $\mathrm{D}b_{(x,0)} = \mathrm{D}\pi_{(x,x)} \circ \mathrm{D}a_{(x,0)}\colon \widetilde{\mathrm{T}}_{(x,0)}\widetilde{\mathrm{T}}M \to \widetilde{\mathrm{T}}_xM \times \widetilde{\mathrm{T}}_xM$ is an isomorphism. It follows from the Inverse Mapping Theorem 24.1 that b is a local diffeomorphism at $(x, 0) \in M \times \{0\}$.

It follows from the above and the Neighborhood Smooth Embedding Theorem 21.13 that there exists an open neighborhood U of $M \times \{0\} \subset \widetilde{\mathrm{T}}M(\mu)$ such that the restriction of b to U is a smooth embedding. We obtain the desired $\nu \in (0, \mu)$ from Claim 1 (b). ■

45.5. **The Smooth Poincaré–Hopf Theorem.** We move on to the most interesting result of this chapter.

Theorem 45.17. (Smooth Poincaré–Hopf Theorem) Let M be a closed orientable smooth manifold and let v be a smooth vector field on M such that all zeros of v are non-degenerate. Then we have the equality[438]

$$\sum_{x \text{ a zero of } v} \mathrm{index}(v, x) \;=\; \chi^{\mathrm{sm}}(M).$$

Remark.

(1) In case the reader is wondering, as we mentioned on page 1019, the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ equals the "usual" Euler characteristic $\chi(M)$, that we will define on page 1519 and on page 1882. In fact in Proposition 129.4, which we will prove twice on page 2821 and on page 2983, we will construct a smooth vector field on M such that all zeros of v are non-degenerate and such that the sum of the indices equals $\chi(M)$. As we point out in Corollary 129.5, this construction together with the Smooth Poincaré–Hopf Theorem 45.17 implies that $\chi(M) = \chi^{\mathrm{sm}}(M)$.

(2) In the Poincaré–Hopf Theorem 129.7 we will reprove the Smooth Poincaré–Hopf Theorem 45.17 and generalize it in two directions:
   (a) We will have a more general notion of the index of a zero of a vector field. Thus we no longer demand that the zeros are non-degenerate, we only demand, that there are only finitely many.
   (b) We will allow compact smooth manifolds with non-empty boundary. If M has boundary, then we will demand that along the boundary ∂M the vector field v is pointing outward.

Our proof of the Smooth Poincaré–Hopf Theorem 45.17 rests on the following proposition, which is interesting in its own right.

[438] Note that by Lemma 45.9 we know that v has only finitely many zeros, so the sum on the left hand side is actually defined.

Proposition 45.18. Let M be a closed orientable k-dimensional smooth submanifold of $\mathbb{R}^n$. As on page 1024 we consider the oriented $2k$-dimensional smooth manifold $\widetilde{\mathrm{T}}M$ and the smooth embedding $\iota\colon M \to \widetilde{\mathrm{T}}M$ that is given by $x \mapsto (x,0)$. Let v be a smooth vector field on M such that all zeros of v are non-degenerate. Then[439]

$$\sum_{x \text{ a zero of } v} \operatorname{index}(v,x) \;=\; \underbrace{\iota(M)\cdot\iota(M)}_{\substack{\text{self-intersection}\\ \text{number in } \widetilde{\mathrm{T}}M}}.$$

Proof. We denote by $x_1,\ldots,x_k$ the zeros of v. We consider the smooth homotopy

$$\begin{array}{rcl} F\colon M\times[0,1] & \to & \widetilde{\mathrm{T}}M \\ (x,t) & \mapsto & x + t\cdot v(x). \end{array}$$

Note that $F_0 = \iota\colon M \to \widetilde{\mathrm{T}}M$ and that $F_1(M) = \operatorname{graph}(v)$. Note that by our hypothesis on v and by Proposition 45.12 we know that $\iota(M) \pitchfork F_1$. The proposition now follows from the following calculation:

$$\begin{array}{ccccc} \displaystyle\sum_{x \text{ a zero of } v} \operatorname{index}(v,x) & = & \displaystyle\sum_{i=1}^{k} \operatorname{index}(v,x_i) & = & \displaystyle\sum_{i=1}^{k} \text{sign of the intersection point} \\ & & & & \qquad (x_i,0) \text{ of } \iota(M) \text{ and } F_1(M) \\ & = & \iota(M)\cdot_{\widetilde{\mathrm{T}}M} F_1(M) & = & \iota(M)\cdot_{\widetilde{\mathrm{T}}M}\iota(M). \\ & & \uparrow & & \uparrow \\ & & \text{by definition} & & \text{by definition of the self-intersection number, here} \\ & & & & \text{we use that } F_1 \text{ is smoothly homotopic to } \iota \end{array}$$

Proposition 45.12 ↓

■

Proof of the Smooth Poincaré–Hopf Theorem 45.17. Let M be a closed orientable smooth manifold and let v be a smooth vector field on M such that all zeros of v are non-degenerate. By the Euclidean Embedding Theorem 27.1 we can assume that M is a smooth submanifold of some $\mathbb{R}^n$.

By the Total Tangent Space-Diagonal Embedding Proposition 45.16 there exists an orientation-preserving smooth embedding

$$f\colon \widetilde{\mathrm{T}}M \;\to\; M\times M$$

such that for each $x \in M$ we have $f(x,0) = (x,x)$. Now we see that

$$\begin{array}{ccccc} \displaystyle\sum_{x \text{ a zero of } v} \operatorname{index}(v,x) & = & \iota(M) \underset{\widetilde{\mathrm{T}}M}{\cdot} \iota(M) & = & \Delta_M \underset{M\times M}{\cdot} \Delta_M \;=\; \chi^{\mathrm{sm}}(M). \\ \uparrow & & \uparrow & & \uparrow \\ \text{by Proposition 45.18} & & \text{follows from } f(\iota(M)) = \Delta_M & & \text{by definition} \\ & & \text{and Lemma 43.3 (2)} & & \end{array}$$

■

Remark. Let M be a closed orientable smooth manifold. In the proof of the Smooth Poincaré–Hopf Theorem 45.17 we showed that $\iota(M)\cdot_{\widetilde{\mathrm{T}}M}\iota(M) = \Delta_M \cdot_{M\times M} \Delta_M = \chi^{\mathrm{sm}}(M)$. In the literature this statement sometimes gets shortened to the catchy and mysterious looking "$M\cdot M = \chi^{\mathrm{sm}}(M)$".

[439] To make sense of the individual terms on the right hand side we have to pick an orientation of M. This orientation then endows $\iota(M)$ and $\widetilde{\mathrm{T}}M$ with an orientation and the self-intersection number $\iota(M)\cdot\iota(M)$ is defined.

45.6. **Applications of the Smooth Poincaré–Hopf Theorem 45.17.** The beauty of the Smooth Poincaré–Hopf Theorem 45.17 is that it can be used for two different purposes:

(1) By constructing suitable vector fields we can use the Smooth Poincaré–Hopf Theorem 45.17 to calculate smooth Euler characteristics.
(2) Once we have calculated the smooth Euler characteristic of a smooth manifold M the Smooth Poincaré–Hopf Theorem 45.17 gives us information on the existence of certain vector fields on M.

In the following we will see both principles in action. First, recall that in Question 45.5 we were challenged to calculate the smooth Euler characteristics of spheres and surfaces of genus g. Fortunately we can now rise to the challenge.

Proposition 45.19. (Sphere-Euler Characteristic Proposition) Given $n \in \mathbb{N}_0$ we have $\chi^{\mathrm{sm}}(S^n) = 1 + (-1)^n$.

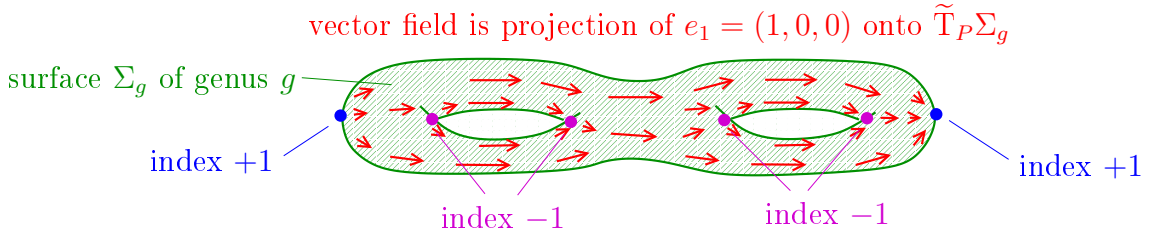
Proof. Let $n \in \mathbb{N}_0$. By Lemma 45.8 we know that there exists a smooth vector field v on S^n with the following properties:

(1) The vector field has precisely two zeros, namely at the South Pole $S = (0, \ldots, 0, -1)$ and at the North Pole $N = (0, \ldots, 0, 1)$.
(2) The two zeros are non-degenerate and the indices are given by $\mathrm{index}(v, S) = 1$ and $\mathrm{index}(v, N) = (-1)^n$.

It now follows that

$$\chi^{\mathrm{sm}}(S^n) \underset{\text{Smooth Poincaré–Hopf Theorem 45.17}}{=} \sum_{x \text{ a zero of } v} \mathrm{index}(v, x) \underset{\text{by the above}}{=} \mathrm{index}(v, S) + \mathrm{index}(v, N) \underset{\text{by the above}}{=} 1 + (-1)^n.$$

■



Proposition 45.20. (Surface-Euler Characteristic Proposition) The smooth Euler characteristic of the surface of genus g equals $2 - 2g$.

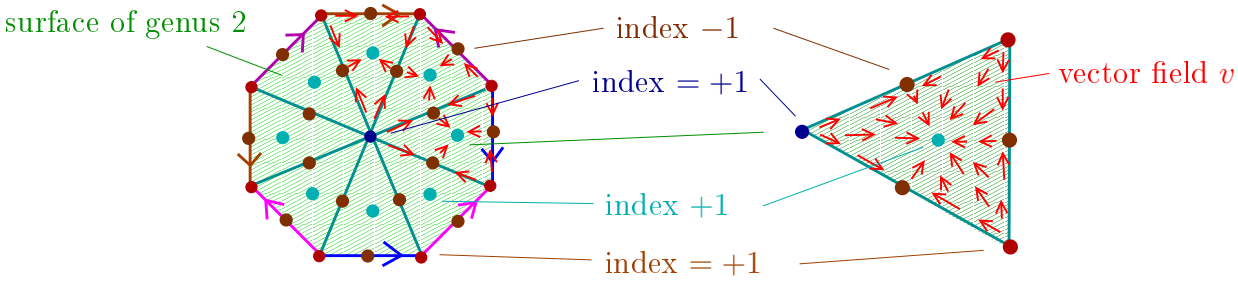
Proof. Let Σ_g be the surface of genus g. We will prove the proposition using the Smooth Poincaré–Hopf Theorem 45.17 and an explicit smooth vector field. In fact we will provide two constructions of smooth vector fields on Σ_g. The first one is slightly informal, the second one is more formal.

(1) First we view Σ_g as a smooth submanifold of $\mathbb{R}^3$ in the "usual way", as shown in the figure below. We denote by v the smooth vector field on Σ_g that is given at each $x \in \Sigma_g$ by projecting the vector $e_1 = (1, 0, 0)$ onto the tangent plane $\widetilde{\mathrm{T}}_x\Sigma_g$. This vector field has non-degenerate zeros of index $+1$ to the "very left" and it has a non-degenerate zero of index $+1$ to the "very right". Furthermore, for each "hole" there exist two non-degenerate zeros of index -1. The are no other zeros. It follows from this discussion that

$$\chi^{\mathrm{sm}}(\Sigma_g) \underset{\text{Smooth Poincaré–Hopf Theorem 45.17}}{=} \sum_{x \text{ a zero of } v} \mathrm{index}(v, x) \underset{\text{by the above}}{=} +1 + 2g \cdot (-1) + 1 = 2 - 2g.$$

(2) We consider the surface $\Sigma_g = E_{4g}/\sim$ as defined on page 266. We construct a smooth vector field v on $E_{4g}/\sim$ as follows:
   (a) We break $E_{4g}/\sim$ into $4g$ triangles, as shown in the figure below.

(b) The vector field v is zero on each vertex, on each midpoint of an edge and on the midpoint of each triangle.
(c) On the edges and on the triangles the vector field v points towards the midpoint.



We make the following observations regarding the number of zeros and the indices of the zeros:[440]

(a) at the two vertices the vectors point outward in all directions, thus the index equals $+1$,
(b) at the midpoints of the $2g + 4g$ edges the vectors point inward in one direction and outward in another direction, thus the index equals -1,
(c) at the midpoints of the $4g$ triangles the vectors point inward from all directions, thus the index equals $+1$.

The vector field is non-zero at all other points. In summary we see that

Smooth Poincaré–Hopf Theorem 45.17

$$\chi^{\mathrm{sm}}(\Sigma_g) \overset{\downarrow}{=} \sum_{x \text{ a zero of } v} \mathrm{index}(v,x) = (+1)\cdot\underbrace{\#\text{vertices}}_{=2} + (-1)\cdot\underbrace{\#\text{edges}}_{=2g+4g} + (+1)\cdot\underbrace{\#\text{triangles}}_{=4g}$$
$$= 2 - 2g - 4g + 4g \qquad = 2 - 2g. \qquad \blacksquare$$

Corollary 45.21. (Surfaces-Non Diffeomorphic Corollary) If $g \neq h$ then the surface of genus g and the surface of genus h are not diffeomorphic.

Remark.

(1) In the Diffeomorphism-to-Standard Surfaces Theorem 142.7 we will show that any closed orientable connected non-empty 2-dimensional smooth manifold is diffeomorphic to some surface of genus g. This theorem together with the above Surfaces-Non Diffeomorphic Corollary 45.21 gives us a diffeomorphism classification of closed orientable connected non-empty 2-dimensional smooth manifolds.

[440] On page 2821 we will generalize this construction and calculation to smooth manifolds that are equipped with a "smooth triangulation".

(2) In the Surfaces-Non Homeomorphic Theorem 55.6 we will see that for $g \neq h$ the surface of genus g and the surface of genus h are in fact not even homeomorphic.
(3) We refer to Chapters 55 and 142 for more information on the classification of 2-dimensional smooth and topological manifolds.

Proof. This corollary follows immediately from the fact, see Lemma 45.3 (2), that the smooth Euler characteristic is a diffeomorphism invariant together with the calculation of the smooth Euler characteristic of surfaces in the Surface-Euler Characteristic Proposition 45.20. ■

The following theorem is an almost immediate consequence of the Smooth Poincaré–Hopf Theorem 45.17

Theorem 45.22. (Smooth Euler Characteristic-Vector Field Theorem) Let M be a closed orientable smooth manifold. If M admits a nowhere-vanishing vector field, then $\chi^{\mathrm{sm}}(M) = 0$.

Remark. In the Euler Characteristic-Vector Field Theorem 97.15 we will reprove the Smooth Euler Characteristic-Vector Field Theorem 45.22 and we will extend the statement to non-orientable smooth manifolds.

Proof. Let M be a closed smooth manifold that admits a nowhere-vanishing vector field. By the Replace-by-Smooth Vector Field Proposition 29.6 we know that M also admits a *smooth* nowhere-vanishing vector field. It follows immediately from the Smooth Poincaré–Hopf Theorem 45.17 that $\chi^{\mathrm{sm}}(M) = 0$. ■

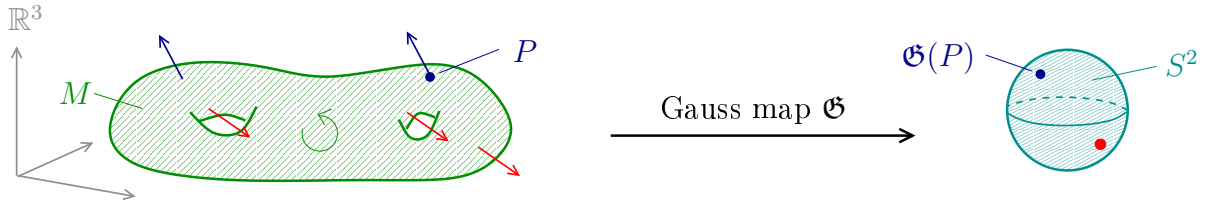
The Smooth Euler Characteristic-Vector Field Theorem 45.22 together with the above calculations of smooth Euler characteristics gives us the following pleasant corollary.

Corollary 45.23.
(1) If $n \in \mathbb{N}_0$ is even, then there is no nowhere vanishing vector field on S^n.
(2) If $g \neq 1$, then there is no nowhere vanishing vector field on the surface Σ_g of genus g.

Remark.
(1) The statement of Corollary 45.23 (1) is of course precisely the content of the Hairy Ball Theorem 38.12.
(2) Corollary 45.23 (2) answers Question 23.19 in the orientable case.

Proof.
(1) Let $n \in \mathbb{N}_0$ be even. By the Sphere-Euler Characteristic Proposition 45.19 we know that $\chi^{\mathrm{sm}}(S^n) = 1 + (-1)^n = 2 \neq 0$. It follows from the Smooth Euler Characteristic-Vector Field Theorem 45.22 that S^n cannot admit a nowhere-vanishing vector field.
(2) Let $g \neq 1$. By the Surface-Euler Characteristic Proposition 45.20 we know that $\chi^{\mathrm{sm}}(\Sigma_g) = 2 - 2g \neq 0$. Thus we see, as in (1), that Σ_g does not admit a nowhere-vanishing vector field. ■

We conclude this section with a sneak preview of a theorem which we will prove later on. This proposition is basically the converse to the Smooth Euler Characteristic-Vector Field Theorem 97.15.



Theorem 129.6. (Nowhere Vanishing Vector Field Existence Theorem) Let M be a closed connected smooth manifold. If $\chi^{\mathrm{sm}}(M) = 0$, then M admits a nowhere-vanishing smooth vector field.

45.7. **The Gauß map I.** In this section we will introduce the Gauß map and we will determine its degree. We will not make use of the results of this section.
The following definition introduces the protagonist of this section.

Definition. Let $n \in \mathbb{N}_0$ and let $M \subset \mathbb{R}^{n+1}$ be a closed oriented smooth submanifold of codimension one. We refer to the map

$$\begin{aligned} \mathfrak{G}\colon M &\to S^n \\ P &\mapsto \begin{array}{l} \text{the unique } \mathfrak{G}(P) \in \mathbb{R}^{n+1} \text{ that has the following properties:} \\ (1)\ \mathfrak{G}(P) \text{ is normal to the physical tangent space } \widetilde{\mathrm{T}}_P M, \\ (2)\ \mathfrak{G}(P) \text{ has length one, i.e. } \mathfrak{G}(P) \in S^n, \\ (3)\ \mathfrak{G}(P) \text{ followed by a positive basis for } \widetilde{\mathrm{T}}_P M \text{ is a positive basis for } \mathbb{R}^{n+1} \end{array} \end{aligned}$$

as the Gauß map of M.[441] [442]

Example. Let $n \in \mathbb{N}$. We consider the submanifold $S^n \subset \mathbb{R}^{n+1}$ with the standard orientation introduced on page 681. It follows almost immediately from the definitions and conventions that the corresponding Gauß map $\mathfrak{G}\colon S^n \to S^n$ is the identity.

The following theorem was first proved by Heinz Hopf [**Hopf1925**] in 1925.

Theorem 45.24. (Gauß Map-Degree Theorem) Let $M \subset \mathbb{R}^{n+1}$ be a closed oriented connected smooth submanifold of codimension one. If n is even, then

$$\deg(\text{Gauß map } \mathfrak{G}\colon M \to \underset{\substack{\uparrow \\ \text{equipped with the standard orientation from page 681}}}{S^n}) \;=\; \tfrac{1}{2} \cdot \chi^{\mathrm{sm}}(M).$$

Remark.

(1) Alternative proofs of the Gauß Map-Degree Theorem 45.24 are given in [**Bre1993**, Theorem VI.12.11], [**Cib2016**], [**Sakk1990**], [**Tu2011**, p. 174] and [**GP1974**, p. 198]. Furthermore we will give a somewhat different proof in Section 129.3.

(2) Note that in general the conclusion of the Gauß Map-Degree Theorem 45.24 does not hold if n is odd. For example if we consider $M = S^1 \subset \mathbb{R}^2$, then we know by the above that the Gauß map $\mathfrak{G}$ is the identity, hence its degree equals one, whereas we saw in the Sphere-Euler Characteristic Proposition 45.19 that $\chi^{\mathrm{sm}}(S^1) = 0$.

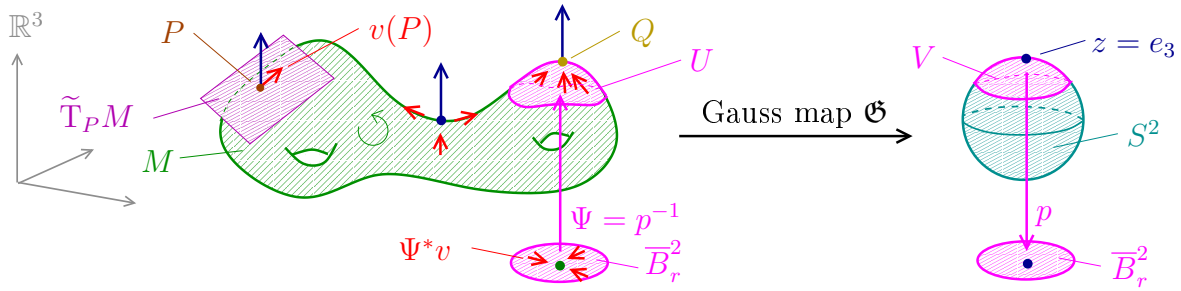
[441] A variation on the Gauß map appeared also in the definition of the rotation number of an immersion $S^1 \to \mathbb{R}^2$ on page 955.
[442] As discussed in the Orientations-via-Normal Vector Fields Proposition 25.11, this map is smooth.

Before we provide a proof of the Gauß Map-Degree Theorem 45.24, let us formulate and prove a neat corollary.

Corollary 45.25. If M is a closed orientable even-dimensional smooth manifold that admits a smooth embedding into $\mathbb{R}^{\dim(M)+1}$, then $\chi^{\mathrm{sm}}(M)$ is even.

Example. Let $n \in \mathbb{N}$. In Exercise 45.5 we will see that $\chi^{\mathrm{sm}}(\mathbb{C}\mathrm{P}^n) = n+1$. Thus, if n is in fact even, then it follows from Corollary 45.25 that the $2n$-dimensional smooth manifold $\mathbb{C}\mathrm{P}^n$ does not admit a smooth embedding into $\mathbb{R}^{2n+1}$. No wonder you never saw a copy of $\mathbb{C}\mathrm{P}^2$ in $\mathbb{R}^5$.

Proof of Corollary 45.25. We write $n = \dim(M)$. By the Smooth Embedding Theorem 24.10 we know that M is diffeomorphic to a smooth submanifold $N \subset \mathbb{R}^{n+1}$. It follows that



$$\chi^{\mathrm{sm}}(M) \underset{\text{Lemma 45.3}}{\uparrow} = \chi^{\mathrm{sm}}(N) \underset{\text{Gauß Map-Degree Theorem 45.24, since } n \text{ is even}}{\uparrow} = 2 \cdot \deg(\text{Gauß map } \mathfrak{G}\colon N \to S^n) \in 2 \cdot \mathbb{Z}.$$

■

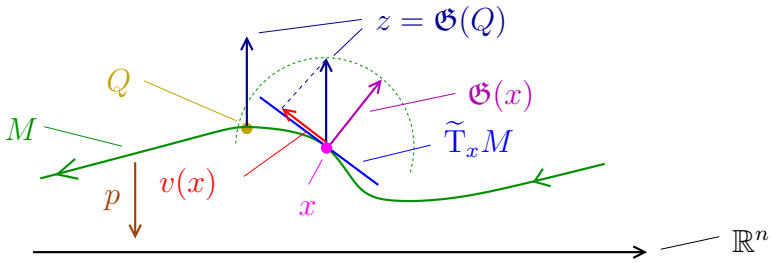
Proof of the Gauß Map-Degree Theorem 45.24. Let $n \in \mathbb{N}_0$ and let $M \subset \mathbb{R}^{n+1}$ be a closed oriented connected smooth submanifold of codimension one. Recall that above we observed that the Gauß map $\mathfrak{G}\colon M \to S^n$ is smooth. Thus we can appeal to Sard's Theorem 31.1 which, together with the Measure-Zero Properties Proposition 30.2, implies that there exists some $z \in S^n$ such that z and $-z$ are both regular values of the Gauß map $\mathfrak{G}$. By the Orthogonal Action Lemma 5.26 we know that $\mathrm{SO}(n+1)$ acts transitively on S^n. It follows easily from this observation, together with Lemma 33.8 and the Degree Homotopy Invariance Theorem 38.3 that, after a rotation, we can assume that $z = e_{n+1} = (0, \ldots, 0, 1) \in \mathbb{R}^{n+1}$. Next we consider the vector field

$$\begin{aligned} v\colon M &\to \mathbb{R}^{n+1} \\ Q &\mapsto \underbrace{z - \langle z, \mathfrak{G}(Q)\rangle \cdot \mathfrak{G}(Q)}_{\text{orthogonal projection of } z \text{ to } \widetilde{\mathrm{T}}_Q M}. \end{aligned}$$

Clearly we have $v(Q) = 0$ if and only if $\mathfrak{G}(Q) = z$ or $\mathfrak{G}(Q) = -z$.

Let $Q \in M$ with $\mathfrak{G}(Q) = \pm z$. By design we know that Q is a regular value of $\mathfrak{G}$. By the Stack of Records Lemma 26.2 (1) we know that $\mathfrak{G}\colon M \to S^n$ is a local diffeomorphism at Q, thus, as on page 898, it makes sense to introduce the following definition:

$$\deg(\mathfrak{G}, Q) = \begin{cases} +1, & \text{if } \mathfrak{G} \text{ is orientation-preserving at } Q \\ -1, & \text{if } \mathfrak{G} \text{ is orientation-reversing at } Q. \end{cases}$$



Claim. Let $Q \in M$.
(1) If $\mathfrak{G}(Q) = z$, then $\operatorname{index}(v, Q) = (-1)^n \cdot \deg(\mathfrak{G}, Q)$.
(2) If $\mathfrak{G}(Q) = -z$, then $\operatorname{index}(v, Q) = \deg(\mathfrak{G}, Q)$.

Proof. First we consider the case that we are given $Q \in M$ with $\mathfrak{G}(Q) = z$. We make the following observations and preparations.

(a) We denote by $p\colon \mathbb{R}^{n+1} \to \mathbb{R}^n$ the projection onto the first n coordinates.
(b) It follows fairly easily from the Inverse Mapping Theorem 24.1, see also Exercise 23.6, that there exists a neighborhood U of $Q \in M$, a neighborhood V of $z \in S^n$ and an $r \in \mathbb{R}_{>0}$ with the following properties:
  (i) We have $\mathfrak{G}(U) \subset V$.
  (ii) The restriction of the projection $p\colon \mathbb{R}^{n+1} \to \mathbb{R}^n$ to $U \subset M$ and $V \subset S^n$ defines diffeomorphisms $p\colon U \to \overline{B}^n_r$ and $p\colon V \to \overline{B}^n_r$. It follows immediately from the orientation conventions and some elementary linear algebra that both maps are orientation-preserving if n is even and both maps are orientation-reversing if n is odd.
(c) We set $\Psi := p^{-1}\colon \overline{B}^n_r \to U$.
(d) Recall that by definition we have $v(x) = z - \langle z, \mathfrak{G}(x)\rangle \cdot \mathfrak{G}(x)$. Using the fact that $\mathfrak{G}(Q) = e$, which implies in particular that $p(\mathfrak{G}(Q)) = p(z) = 0$, one can easily show, using the Product Rule for partial differentials, that[443]

$$\mathrm{D}(p \circ (x \mapsto -v(x)) \circ \Psi)_{p(Q)} \;=\; \mathrm{D}(p \circ \mathfrak{G} \circ \Psi)_{p(Q)}.$$

This fact is also illustrated, more or less convincingly, in the figure below.

We now see that

$$\begin{array}{lcll} \deg(\mathfrak{G}, Q) = +1 & \overset{\text{we know that } p \text{ and } \Psi \text{ are either both orientation-preserving or they are both orientation-reversing}}{\Longleftrightarrow} & \det(\mathrm{D}(p \circ \mathfrak{G} \circ \Psi)_{p(Q)}) > 0 & \overset{\text{by (d)}}{\Longleftrightarrow} \det(\mathrm{D}(p \circ (x \mapsto -v(x)) \circ \Psi)_{p(Q)} > 0 \\ & \Longleftrightarrow & \det(\mathrm{D}(\underbrace{p^*(-v)}_{\text{pullback of } -v})_{p(Q)} > 0 & \Longleftrightarrow \quad (-1)^n \cdot \det(\mathrm{D}(p^* v)_{p(Q)} > 0 \\ & & & \Longleftrightarrow \quad \operatorname{index}(v, Q) = (-1)^n. \end{array}$$

Now we consider the case that $\mathfrak{G}(Q) = -z$. The calculation is basically identical to the above. The only difference is that in this setting the map p is orientation-preserving if and

[443] Note that if W is an open subset of $\mathbb{R}^n$ and if $f\colon W \to \mathbb{R}$ and $g\colon W \to \mathbb{R}^n$ are smooth maps, then it follows immediately from the Product Rule for partial differentials that for any $w \in W$ we have

$$\mathrm{D}(f \cdot g)_w \;=\; (\tfrac{\partial f}{\partial x_1}(w) \cdot g(w) \ldots \tfrac{\partial f}{\partial x_n}(w) \cdot g(w)) + f(w) \cdot \mathrm{D}g_w.$$

We now apply this scheme to $f(y) = \langle z, (\mathfrak{G} \circ \Psi)(y)\rangle$ and $g = p \circ \mathfrak{G} \circ \Psi$ and we obtain the desired equality.

only if n is odd, whereas before p was orientation-preserving if and only if n is even. On the other hand the behavior of the orientation of Ψ does not change, i.e. Ψ is orientation-preserving if and only if n is even. Thus we obtain the same result as above, except that by Lemma 76.16 we pick up a sign $(-1)^n$. ⊞

We turn to the actual proof of the promised equality. Thus we now assume that n is even. We perform the following calculation:

$$\begin{array}{rcl} 2\cdot\deg(\text{Gauß map } \mathfrak{G}\colon M\to S^n) & \overset{\text{since } z \text{ and } -z \text{ are regular values we can apply the Local-Global Degree Proposition 101.6 to } z \text{ and to } -z}{\downarrow} & \\ & = \sum_{\substack{Q\in M \text{ with} \\ \mathfrak{G}(Q)=z}} \deg(\mathfrak{G},Q) + \sum_{\substack{Q\in M \text{ with} \\ \mathfrak{G}(Q)=-z}} \deg(\mathfrak{G},Q) & \\ & = \sum_{\substack{Q\in M \text{ with} \\ v(Q)=0}} \deg(\mathfrak{G},Q) & = \sum_{\substack{Q\in M \text{ with} \\ v(Q)=0}} \operatorname{index}(v,Q) = \chi^{\mathrm{sm}}(M). \\ & \uparrow & \uparrow \qquad\qquad\qquad \uparrow \\ & \text{since } v(Q)=0 \text{ if and only if } \mathfrak{G}(Q)=z \text{ or } \mathfrak{G}(Q)=-z & \text{by the claim and since } n \text{ is even} \qquad \text{Smooth Poincaré-Hopf Theorem 45.1} \blacksquare \end{array}$$

Remark. This concludes our discussion of the algebraic (self-) intersection number for the time being. We will return to the study of algebraic (self-) intersection numbers much later in Chapter 126 when we will relate it to the cup product on cohomology.

Exercises for Chapter 45.

Exercise 45.1.

(a) Let M and N be two closed oriented smooth manifold. Show that

$$\chi^{\mathrm{sm}}(M\times N) \;=\; \chi^{\mathrm{sm}}(M)\cdot\chi^{\mathrm{sm}}(N).$$

(b) Show that given any $k\in\mathbb{Z}_{\geq 2}$ there exist closed orientable connected $2k$-dimensional smooth manifolds of arbitrarily large and arbitrarily low values for the smooth Euler characteristic.

Exercise 45.2.

(a) Let M be a closed $2n$-dimensional smooth manifold and let $X\subset M$ be a closed submanifold. We do not make any assumptions on orientability. Show that one can still introduce a $\mathbb{Z}_2$-algebraic self-intersection number $X\cdot_{\mathbb{Z}_2} X\in\mathbb{Z}_2$ in a reasonable way.

(b) Let $\iota\colon \mathbb{R}\mathrm{P}^1\to\mathbb{R}\mathrm{P}^2$ be the smooth embedding given by $[x_0:x_1]\mapsto[x_0:x_1:x_2]$. Determine the $\mathbb{Z}_2$-algebraic self-intersection number of $\iota(\mathbb{R}\mathrm{P}^1)\subset\mathbb{R}\mathrm{P}^2$.

Exercise 45.3. We consider the smooth embedding

$$\begin{array}{rcl} \iota\colon \mathbb{C}\mathrm{P}^1 & \to & \mathbb{C}\mathrm{P}^2 \\ [z_0:z_1] & \mapsto & [z_0:z_1:z_2]. \end{array}$$

Determine the algebraic self-intersection number of $\iota(\mathbb{C}\mathrm{P}^1)\subset\mathbb{C}\mathrm{P}^2$.

Remark. We know by the Complex Projective Space-is-Complex Manifold Lemma 32.16 that each $\mathbb{C}\mathrm{P}^n$ is a closed oriented $2n$-dimensional smooth manifold.

Exercise 45.4. Let M be a smooth submanifold of some $\mathbb{R}^n$ and let $f\colon M \to \mathbb{R}$ be a smooth function. Let $P \in M \setminus \partial M$ be a critical point. We pick a chart $\Phi\colon U \to V$ for P. We write $Q := \Phi(P)$. In Lemma 137.1 we will see that the congruence class of the Hessian matrix

$$\operatorname{Hess}(f \circ \Phi^{-1})_Q \;:=\; \left(\frac{\partial^2}{\partial x_i\, \partial x_j}\Big|_Q f \circ \Phi^{-1} \right)_{i,j=1,\dots,n} \;\in\; \mathrm{M}(n \times n, \mathbb{R})$$

is independent of the choice of the chart. We say the critical point P is *non-degenerate* if $\det(\operatorname{Hess}(f \circ \Phi^{-1})_Q) \neq 0$. We refer to

$$\operatorname{index}(f, P) \;:=\; \text{number of negative eigenvalues of } \operatorname{Hess}(f \circ \Phi^{-1})_Q$$

as the *index of the critical point* P. Next we consider the vector field that is given by

$$\begin{array}{rcl} \nabla f\colon M & \to & \mathbb{R}^n \\ x & \mapsto & \begin{array}{c}\text{the unique } v(x) \in \widetilde{\mathrm{T}}_x M \text{ such that for} \\ \text{all } w \in \widetilde{\mathrm{T}}_x M \text{ we have } \langle v(x), w\rangle = \mathrm{D}f_x(w).\end{array} \end{array}$$

We refer to it as the *gradient vector field of* f. Show that for every $x \in M$ the following statements hold:

(a) x is a critical point of f if and only if x is a zero of ∇f.
(b) If x is a critical point of f, then x is a non-degenerate critical point of f if and only if x is a non-degenerate zero of ∇f.
(c) If x is a non-degenerate critical point of f, then $\operatorname{index}(\nabla f, x) = (-1)^{\operatorname{index}(f,x)}$.

Exercise 45.5. Let $n \in \mathbb{N}_0$. We pick real numbers $c_0 < c_1 < \cdots < c_n$. We consider the following functions on $\mathbb{R}\mathrm{P}^n = S^n/\{\pm\mathrm{id}\}$ and $\mathbb{C}\mathrm{P}^n = S^{2n+1}/S^1$:

$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^n & \to & \mathbb{R} \\ [x_0 : \cdots : x_n] & \mapsto & \sum_{j=0}^{n} c_j \cdot x_j^2 \end{array} \qquad \text{and} \qquad \begin{array}{rcl} g\colon \mathbb{C}\mathrm{P}^n & \to & \mathbb{R} \\ [z_0 : \cdots : z_n] & \mapsto & \sum_{j=0}^{n} c_j \cdot |z_j|^2. \end{array}$$

By the Smooth Embedding Theorem 24.10 we can think of $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ as smooth submanifolds of some $\mathbb{R}^N$. This allows us to consider the corresponding gradient vector fields ∇f and ∇g that we introduced in Exercise 45.4.

(a) Show that ∇f has precisely $n+1$ zeros, that these are non-degenerate and that the indices are $1, -1, \dots, (-1)^{n+1}$.
(b) Show that ∇g has precisely $n+1$ zeros, that these are non-degenerate and that the index is always $+1$.

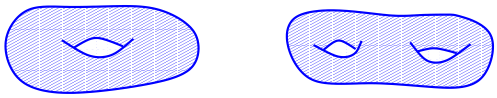
Remark. You might want to use the explicit charts given in Exercise 19.16 and the Complex Projective Space-is-Complex Manifold Lemma 32.16.
Remark. Note that it follows from this exercise together with the Smooth Poincaré–Hopf Theorem 45.17 that $\chi^{\mathrm{sm}}(\mathbb{R}\mathrm{P}^n) = \frac{1}{2}(1 + (-1)^n)$ and that $\chi^{\mathrm{sm}}(\mathbb{C}\mathrm{P}^n) = n + 1$.

Exercise 45.6. Let M be a closed orientable smooth manifold and let $p \in M$. Does there necessarily exist a smooth embedding $f\colon M \to M \times M$ such that for every $x \in M$ we have $f(x) = (x, p)$?

Exercise 45.7. Let $p\colon \widetilde{M} \to M$ be a local diffeomorphism between two closed oriented connected non-empty smooth manifolds.

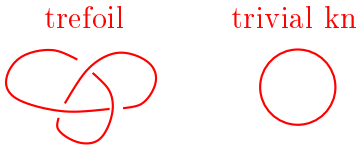
(a) Show that for any $x, y \in M$ we have $\#p^{-1}(x) = \#p^{-1}(y)$ and show that the cardinality of this set is finite.
(b) Show that the cardinality of the set in (a) equals $|\deg(p)|$.
(c) Show that $\chi^{\mathrm{sm}}(\widetilde{M}) = \deg(p) \cdot \chi^{\mathrm{sm}}(M)$.
(d) Given $k \in \mathbb{N}$ we denote by N_k the non-orientable surface of genus k as defined on page 266. Show that N_k admits a nowhere vanishing smooth vector field if and only if $k = 2$.
Hint. Make use of Exercise 19.37.

Part V



Fundamental Groups

46. How can we show that two topological spaces are (not) homeomorphic?



In the previous two sections we collected many examples of topological spaces. In many cases it was relatively straightforward to see that two topological spaces are homeomorphic. For example we wrote down an explicit homeomorphism from $\mathbb{R}^n/\mathbb{Z}^n$ to $(S^1)^n$. Sometimes it is rather painful to explicitly write down a homeomorphism, for example it was not particularly easy to find a homeomorphism from the open cube $(0,1)^n$ to the open ball $B^n = \{x \in \mathbb{R}^n \,|\, \|x\| < 1\}$. Nonetheless, if two topological spaces are homeomorphic, then usually one can write down an explicit homeomorphism.
On the other hand, how can we tell that two topological spaces are not homeomorphic? There are a couple of trivial criteria: being compact, connected, Hausdorff are properties of topological spaces that are shared by homeomorphic topological spaces. This implies for example that the closed cube $[0,1]^n$ is not homeomorphic to the open cube $(0,1)^n$, since the former topological space is compact and the latter is not.
But these criteria are of no use when it comes to studying more subtle examples. For example they do not suffice to address the following questions:

(1) Can surfaces with different genera be homeomorphic?
(2) Given $k \in \mathbb{Z}_{\geq 0}$ we denote by U the complement of k points in $\mathbb{R}^2$. If $k \neq l$, is it possible that U_k and U_l are homeomorphic?
(3) Is the complement of the trefoil homeomorphic to the complement of the trivial knot?

In each case we suspect that the answer is no. Certainly we do not succeed in finding a homeomorphism, but how can we show that this is not due to lack of imagination, but that there is indeed no homeomorphism?

are these surfaces homeomorphic?

are the complements homeomorphic?

The reader might have encountered some ideas for tackling these questions in one or both of the following topics:

(a) Differential forms on smooth manifolds, in particular de Rham cohomology, as developed say in [**BoT1982, Lee2002**].
(b) Complex analysis, see e.g. [**Lang1999, Jä2011**].

For the reader who has seen differential forms and de Rham cohomology we recall that each smooth manifold M and each $k \in \mathbb{Z}_{\geq 0}$ we can assign the de Rham cohomology group $H^k_{\mathrm{dR}}(M)$. It follows more or less from the definition that diffeomorphic smooth manifolds have isomorphic de Rham cohomology groups. This approach has several disadvantages:

(1) the de Rham cohomology groups are only defined for smooth manifolds,
(2) the de Rham cohomology groups can only be used to show that two smooth manifolds are not *diffeomorphic*, a priori they cannot be used to show that two smooth manifolds are not *homeomorphic*,

(3) at least just starting from the definition it is not clear how one can calculate the de Rham cohomology groups of a given smooth manifold.

Later on, in Chapter 108, we will introduce "singular cohomology" which will take care of all of these three issues.

Next we give some definitions that are familiar to the reader who has taken a course on complex analysis.

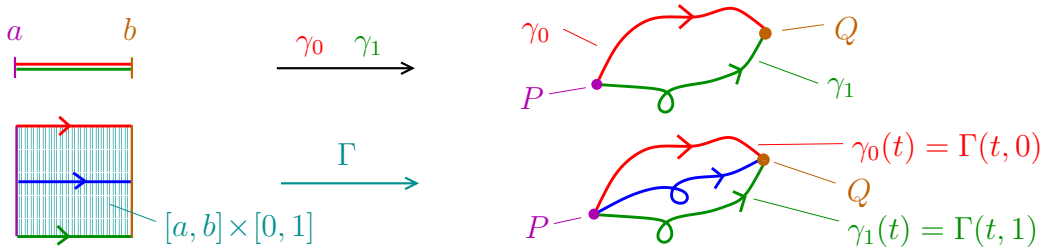
Definition.

(1) Given a subset U of $\mathbb{C}$, we define a path in U to be a map $\gamma\colon [a,b] \to U$. If $\gamma(a) = \gamma(b)$, then we say that γ is a loop.

(2) Two paths $\gamma_0, \gamma_1\colon [a,b] \to U$ with the same starting point $P := \gamma_0(a) = \gamma_1(a)$ and the same endpoint $Q := \gamma_0(b) = \gamma_1(b)$ are called path-homotopic in U, if there exists a homotopy rel $\{a,b\}$ from γ_0 to γ_1. In other words, if there exists a map

$$\begin{array}{rcl} \Gamma\colon [a,b]\times[0,1] & \to & U \\ (t,s) & \mapsto & \Gamma(t,s), \end{array}$$

with the following properties[444]



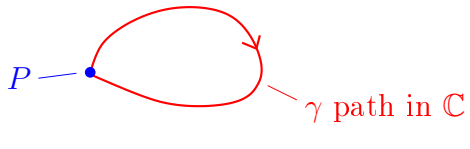
(a) for every $t \in [a,b]$ we have $\Gamma(t,0) = \gamma_0(t)$ and $\Gamma(t,1) = \gamma_1(t)$,

(b) for every $s \in [0,1]$ we have $\Gamma(a,s) = P$ and $\Gamma(b,s) = Q$.

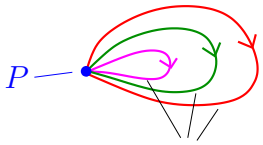
In the figure below we illustrate a path-homotopy between two paths.

(3) A loop $\gamma\colon [a,b] \to U$ is called null-homotopic if it is path-homotopic to the constant path given by $\delta(t) := \gamma(a)$ for all $t \in [a,b]$.

(4) We say U is simply connected if U is non-empty, if U is path-connected and if each loop is null-homotopic.



Example. Every loop in $\mathbb{R}^2 = \mathbb{C}$ is null-homotopic. Indeed, we let $\gamma\colon [0,1] \to \mathbb{C}$ be a loop with starting and endpoint P. Then



$$\begin{array}{rcl} \Gamma\colon [a,b]\times[0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \gamma(t)\cdot(1-s) + P\cdot s \end{array}$$

is a path-homotopy between the loop γ and the constant path at P.

Next we recall the following definition from page 791.

[444] Loosely speaking a path-homotopy between two paths consists of a "continuous" family of paths $\{\Gamma(-,s)\}_{s\in[0,1]}$ from P to Q which interpolates between the paths γ_0 and γ_1.

path-homotopy from γ to a constant path

Definition. Let $U \subset \mathbb{C}$ be an open subset, let $f\colon U \to \mathbb{C}$ be a map and let $\gamma\colon [a,b] \to U$ be a smooth path. We define the path integral of f along γ as follows:

$$\int_\gamma f(z)\,dz \;:=\; \int_{t=a}^{t=b} f(\gamma(t)) \cdot \gamma'(t)\,dt \;\in \mathbb{C}.$$

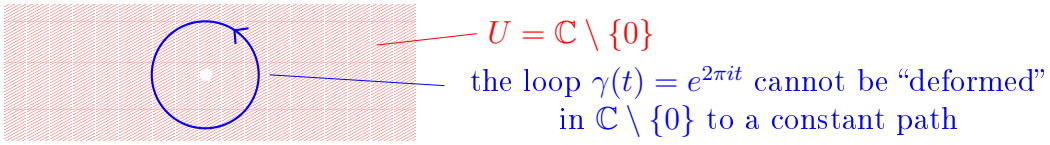
We also recall the following examples from page 791.

Examples.

(1) Let $U = \mathbb{C} \setminus \{0\}$, let $f(z) = \frac{1}{z}$ and let $\gamma\colon [0,1] \to \mathbb{C} \setminus \{0\}$ be the loop given by $\gamma(t) = \exp(2\pi\,\mathrm{i}t)$, i.e. γ is a loop that "goes once around the origin". Then

$$\int_\gamma f(z)\,dz \;=\; \int_{t=0}^{t=1} f(\gamma(t)) \cdot \gamma'(t)\,dt \;=\; \int_{t=0}^{t=1} \frac{1}{\exp(2\pi\,\mathrm{i}t)} \cdot \exp(2\pi\,\mathrm{i}t) \cdot 2\pi\,\mathrm{i}\,dt \;=\; 2\pi\,\mathrm{i}.$$

(2) If γ is a constant path, then $\gamma'(t) \equiv 0$. This shows that the path-integral along a constant path is zero.



We also recall the following theorem.

Theorem ??. (Cauchy Theorem) Let $U \subset \mathbb{C}$ be an open subset, let $f\colon U \to \mathbb{C}$ be a holomorphic function and let $\gamma, \delta\colon [a,b] \to U$ be two smooth paths. If γ and δ are path-homotopic, then

$$\int_\gamma f(z)\,dz \;=\; \int_\delta f(z)\,dz.$$

The following corollary is a consequence of the Cauchy Theorem **??** and of the above calculations.

Corollary 46.1. The loop $\gamma\colon [0,1] \to \mathbb{C} \setminus \{0\}$ given by $\gamma(t) = \exp(2\pi\,\mathrm{i}t)$ is *not* path-homotopic to a constant path, i.e. γ is not null-homotopic.

Remark. In the following Chapter 46.1 we will use Corollary 46.1 so that we have at least one non-trivial topological statement in our toolbox. Somewhat later, after somewhat lengthy preparations, we will prove a general result, namely Corollary 48.18, which in particular will provide us with a new proof of Corollary 46.1.

Example. If two subsets of $\mathbb{C}$ are homeomorphic, then evidently either both are simply connected or none is. From Corollary 46.1 it now follows immediately that $\mathbb{R}^2 = \mathbb{C}$ and $\mathbb{R}^2 \setminus \{(0,0)\} = \mathbb{C} \setminus \{0\}$ are not homeomorphic.

This second approach to showing that two topological spaces are different also has several disadvantages over the first approach:

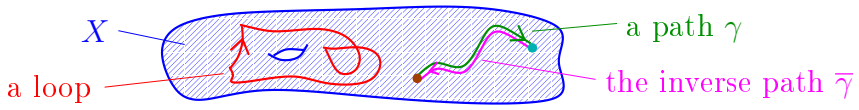
(1) A priori these notions are defined only for subsets of $\mathbb{C}$,
(2) this approach does not allow us to show that the two subsets $U = \mathbb{C} \setminus \{0\}$ and $V = \mathbb{C} \setminus \{0, 1\}$ are not homeomorphic, since neither is simply connected.

The first objection is of course easy to rectify, since the definitions make sense for any topological space. But if we work with more general situations a new problem arises: how can we show, without using complex analysis, that a topological space is not simply connected? In the following chapters we will address all these issues.

In particular, when it comes to distinguishing $U = \mathbb{C} \setminus \{0\}$ and $V = \mathbb{C} \setminus \{0, 1\}$, then naively we would say that V has "more" loops that are not null-homotopic than U. In the Chapter 47 we will in particular make precise what "more" means.

47. The fundamental group

47.1. **Path-homotopy classes of paths.** In this section we extend some of the ideas and notions about paths that we introduced in the previous section to the more general setting of paths in topological spaces. The following definition is a slight generalization of the concept of a path that we initially introduced on page 161.



Definition. Let X be a topological space.

(1) We define a path in X as a[445] map $\gamma\colon [a,b] \to X$. We call $\gamma(a)$ the starting point of γ and we call $\gamma(b)$ the endpoint of γ. Often we say that γ is a path from $\gamma(a)$ to $\gamma(b)$.

(2) A loop is a path for which the starting point and the endpoint coincide.

Convention. In the following, if we do not specify the domain of a path or a loop, then it is understood to be $[0,1]$.

Definition. Given a path $\gamma\colon [a,b] \to X$ we refer to the path $\overline{\gamma}\colon [a,b] \to X$ that is given by $\overline{\gamma}(t) = \gamma(b+a-t)$ as the inverse path of γ.

Definition. Let X be a topological space.

(1) Let $\gamma_0, \gamma_1\colon [a,b] \to X$ be two paths with the same starting point P and the same endpoint Q. A path-homotopy between the paths γ_0 and γ_1 is a homotopy rel $\{a,b\}$ between γ_0 and γ_1. In other words, spelling out the definition on page 419, a path-homotopy is a map

$$\begin{array}{rcl} \Gamma\colon [a,b]\times[0,1] & \to & X \\ (t,s) & \mapsto & \Gamma(t,s), \end{array}$$

with the following properties:

(a) for every $t \in [a,b]$ we have $\Gamma(t,0) = \gamma_0(t)$ and $\Gamma(t,1) = \gamma_1(t)$,

(b) for every $s \in [0,1]$ we have $\Gamma(a,s) = P$ and $\Gamma(b,s) = Q$.

(2) If there exists a path-homotopy between two paths γ_0 and γ_1, then we say that γ_0 and γ_1 are path-homotopic, and we write $\gamma_0 \simeq \gamma_1$.

(3) We say a loop $\gamma\colon [a,b] \to X$ is null-homotopic, if it is path-homotopic to the constant path δ given by $\delta(t) = \gamma(a)$ for all $t \in [a,b]$.

Examples.

(A) Let C be a convex subset of $\mathbb{R}^n$ and let $\gamma_0, \gamma_1\colon [a,b] \to C$ be two paths in C with same starting point and the same endpoint. As in the Convex Homotopy Lemma 14.1 we see that

$$\begin{array}{rcl} \Gamma\colon [a,b]\times[0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \gamma_0(t)\cdot(1-s) + \gamma_1(t)\cdot s \end{array}$$

is a path-homotopy between γ_0 and γ_1.[446]

[445] Recall that all maps are understood to be continuous, unless we say something else.

[446] We had already illustrated this fact in the figure on page 1046.

(B) Let $X = \mathbb{C} \setminus \{0\} = \mathbb{R}^2 \setminus \{(0,0)\}$. As we had just seen in Corollary 46.1, the path

$$\begin{array}{rcl} \gamma\colon [0,1] & \to & X \\ t & \mapsto & \exp(2\pi\,\mathrm{i}t) = (\cos(2\pi t), \sin(2\pi t)) \end{array}$$

is not null-homotopic in X.

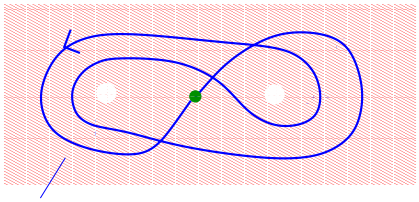
(C) Let $Y = S^1 \times (0,2)$ and consider the loop

$$\begin{array}{rcl} \widetilde{\gamma}\colon [0,1] & \to & Y = S^1 \times (0,2) \\ t & \mapsto & (\exp(2\pi\,\mathrm{i}t), 1). \end{array}$$

This loop is not null-homotopic. This can be seen as follows: we consider the map

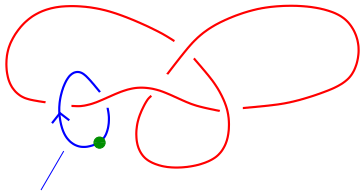
$$\begin{array}{rcl} \Phi\colon Y = S^1 \times (0,2) & \to & X = \mathbb{C} \setminus \{0\} \\ (z,t) & \mapsto & z \cdot t. \end{array}$$

If $\widetilde{\gamma}$ was null-homotopic in Y, then there would exist a path-homotopy



$$\widetilde{F}\colon [0,1] \times [0,1] \to Y$$

from $\widetilde{\gamma}$ to the constant path $\widetilde{\delta}(t) := (1,1)$, $t \in [0,1]$. But then



$$F := \Phi \circ \widetilde{F}\colon [0,1] \times [0,1] \to X$$

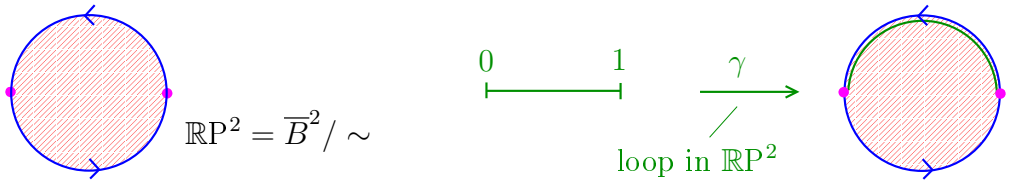
would be a path-homotopy in $X = \mathbb{C} \setminus \{0\}$ from the path $\gamma := \Phi \circ \widetilde{\gamma}$ to the constant path $\delta := \Phi \circ \widetilde{\delta}$. But $\gamma = \Phi \circ \widetilde{\gamma}$ is precisely the path γ from example (B) which we showed not to be null-homotopic in $X = \mathbb{C} \setminus \{0\}$.

(D) We consider the two loops in the figure below. In both cases it is hard to see how these loops could possibly be path-homotopic to a constant path, but it is also difficult to find an argument why that should not be possible.[447]

loop in $\mathbb{C} \setminus \{0,1\}$

loop in the complement of a knot

(E) We consider the real projective space $\mathbb{R}\mathrm{P}^2$. Recall that in Lemma 5.32 we gave an identification $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$ where $\sim$ is the equivalence relation on $\overline{B}^2$ generated by $P \sim -P$ for $P \in S^1 = \partial\overline{B}^2$. Then



$$\begin{array}{rcl} \gamma\colon [0,1] & \to & \overline{B}^2/\!\sim \\ t & \mapsto & [(\cos(\pi t), \sin(\pi t))] \end{array}$$

is a loop in $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$.[448] But is it null-homotopic?

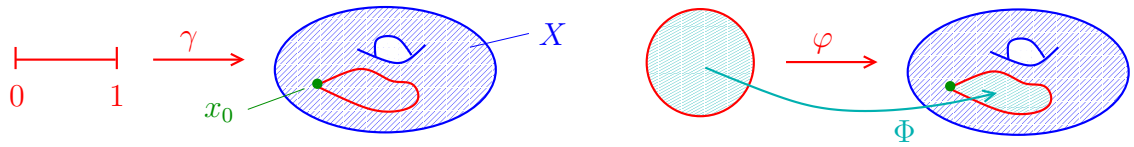
(F) On page 141 we considered the pseudocircle, namely the set $X = \{A, B, C, D\}$ with a slightly unusual topology. Furthermore we gave an example of a continuous non-constant loop $f\colon S^1 \to X$. The question arises, is this loop null-homotopic?

[447] For example the given loop in $\mathbb{C} \setminus \{0,1\}$ is actually null-homotopic in $\mathbb{C} \setminus \{0\}$ and it is null-homotopic in $\mathbb{C} \setminus \{1\}$. In particular our trick of using Corollary 46.1 does not work in this case.

[448] Why is it a loop?

Remark. Let X be a topological space and let $x_0 \in X$. It follows from Lemma 5.18 that the maps

$$\begin{array}{rcl} \{\text{loops } \gamma\colon [0,1] \to X \text{ with } \gamma(0) = \gamma(1) = x_0\} & \Leftrightarrow & \{\text{maps } f\colon S^1 \to X \text{ with } f(1) = x_0\} \\ (\gamma\colon [0,1] \to X) & \mapsto & (z = \exp(2\pi\,\mathrm{i}t) \mapsto \gamma(t)) \\ (t \mapsto f(\exp(2\pi\,\mathrm{i}t))) & \leftarrow\!\shortmid & (f\colon S^1 \to X) \end{array}$$

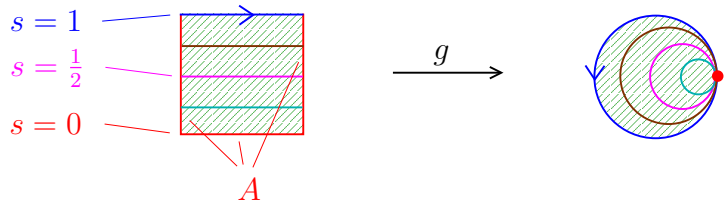


are evidently bijections. Thus we can think of loops in X where the starting and endpoint is x_0 as maps from S^1 to X that send 1 to x_0. We will use this bijection to go back and forth between these two points of view.

The following lemma gives a useful criterion for a loop to be null-homotopic.

Lemma 47.1. (Extension-to-Disk Lemma) Let X be a topological space and let $x_0 \in X$. Let $\gamma\colon [0,1] \to X$ be a loop with $\gamma(0) = \gamma(1) = x_0$. We denote by

$$\begin{array}{rcl} \varphi\colon S^1 & \to & X \\ z = \exp(2\pi\,\mathrm{i}t) & \mapsto & \gamma(t) \end{array}$$



the corresponding map from S^1 to X. Then γ is null-homotopic if and only if there exists a map $\Phi\colon \overline{B}^2 \to X$ so that $\Phi|_{S^1} = \varphi$.

Proof. We start out this proof with a few rather elementary preparations. We write $A := ([0,1] \times \{0\}) \cup (\{0,1\} \times [0,1])$ and we consider the map

$$\begin{array}{rcl} g\colon [0,1] \times [0,1] & \to & \overline{B}^2 \\ (t,s) & \mapsto & s\exp(2\pi\,\mathrm{i}t) + 1 - s. \end{array}$$

Note that this map has the property that all points in A get sent to $1 \in S^1$. Using this

observation, the Topological-Quotient Proposition 5.15 (1b) and the Compact-Hausdorff Proposition 2.17 (3) we see that the map

$$\begin{array}{rcl} h\colon ([0,1] \times [0,1])/A & \to & \overline{B}^2 \\ [P] & \mapsto & g(P) \end{array}$$

is a homeomorphism.

Now we turn to the actual proof of the lemma. Thus let X be a topological space, let $x_0 \in X$ and let $\gamma\colon [0,1] \to X$ be a loop with $\gamma(0) = \gamma(1) = x_0$. We define $\varphi\colon S^1 \to X$ via $\varphi(\exp(2\pi\,\mathrm{i}t)) = \gamma(t)$.

First we suppose that γ is null-homotopic. This means that there exists a path-homotopy $F\colon [0,1] \times [0,1] \to X$ such that $F(t,0) = x_0$ and $F(t,1) = \gamma(t)$ for all $t \in [0,1]$ and such that $F(0,s) = F(1,s) = x_0$ for all $s \in [0,1]$. In other words, F is constant on A. We consider the map[449]

$$\begin{array}{rccc} \Phi\colon \overline{B}^2 & \underset{\cong}{\overset{h}{\leftarrow}} & ([0,1]\times[0,1])/A & \to & X \\ & & [P] & \mapsto & F(P). \end{array}$$

One can easily verify that we have $\Phi|_{S^1} = \varphi$.

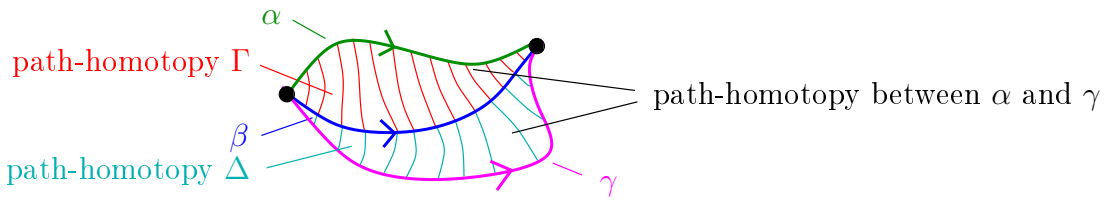
Conversely, if there exists a map $\Phi\colon \overline{B}^2 \to X$ so that $\Phi|_{S^1} = \varphi$, then one can easily verify that $\Phi \circ g\colon [0,1] \times [0,1] \to X$ is a path-homotopy from the loop γ to the constant loop c_{x_0}.[450] ■

Before we continue with the examples we need to gather a few more elementary facts about path-homotopies of paths. The following lemma is a special case of Lemma 14.5.

Lemma 47.2. Let X be a topological space and let $x, y \in X$. Then "path-homotopy" is an equivalence relation on the set of paths $\gamma\colon [a,b] \to X$ from x to y.

Proof. This lemma is just the special case Lemma 14.5 with $X = [a,b]$ and $A = \{a,b\}$. For the reader's convenience we provide the straightforward proof also in this context. We have to show that "path-homotopy" satisfies the three properties of an equivalence relation. Let $\alpha, \beta, \gamma\colon [a,b] \to X$ be three paths from x to y.

(1) The "constant path-homotopy" given by $\Gamma(t,s) := \gamma(t)$ defines a path-homotopy between γ and γ.
(2) Let Γ be a path-homotopy from α to β. It is basically clear that the map Γ' defined by $\Gamma'(t,s) := \Gamma(t, 1-s)$ is a path-homotopy from β to α.
(3) Let Γ be a path-homotopy from α to β and let Δ be a path-homotopy from β to γ. We consider the map



$$\begin{array}{rcl} [a,b]\times[0,1] & \to & X \\ (t,s) & \mapsto & \begin{cases} \Gamma(t,2s), & \text{if } s \in \left[0, \frac{1}{2}\right], \\ \Delta(t,2s-1), & \text{if } s \in \left(\frac{1}{2}, 1\right] \end{cases} \end{array}$$

It follows from the Homotopy Stacking Lemma 14.3 that this map is continuous. It is now clear that this map is a path-homotopy from α to γ. ■

Definition. Given a path $f\colon [0,1] \to X$ in a topological space X we denote by $[f]$ the equivalence class of f with respect to the equivalence relation which is given by path-homotopies. We call $[f]$ the path-homotopy class of f.

[449] Note that we implicitly use the Topological-Quotient Proposition 5.15 (1b) to argue that the map $([0,1]\times[0,1])/A \to X$ is well-defined and continuous.

[450] Why did we not just define g to be the map that sends the horizontal lines to concentric circles where each of them is centered around the origin?

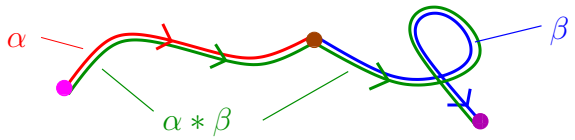
Definition. Let $\gamma\colon [a,b] \to X$ be a path in a topological space and let $\varphi\colon [a,b] \to [a,b]$ be a map[451] with $\varphi(a) = a$ and $\varphi(b) = b$. We refer to $\gamma \circ \varphi\colon [a,b] \to X$ as a reparametrization of γ.

The following lemma says that reparametrizing does not change the path-homotopy class of a path.

Lemma 47.3. Let $\gamma\colon [a,b] \to X$ be a path in a topological space. If a path $\delta\colon [a,b] \to X$ is obtained from γ by a reparametrization, then γ and δ are path-homotopic.

Proof. Let $\gamma\colon [a,b] \to X$ be a path in a topological space and let $\varphi\colon [a,b] \to [a,b]$ be a map with $\varphi(a) = a$, $\varphi(b) = b$. A path-homotopy between γ and $\gamma \circ \varphi$ is given by[452]

$$\begin{array}{rccl} P\colon [a,b] \times [0,1] & \to & X \\ (t,s) & \mapsto & \gamma(t \cdot s + \varphi(t) \cdot (1-s)). \end{array}$$



■

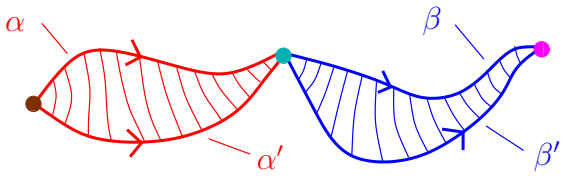
We now recall the following definition from page 165.

Definition. Let X be a topological space and let $\alpha\colon [a,b] \to X$ and $\beta\colon [c,d] \to X$ be two paths with $\alpha(b) = \beta(c)$. We define the concatenation of α and β as the path $\alpha * \beta$ which is given by

$$\begin{array}{rccl} \alpha * \beta\colon [0,1] & \to & X \\ t & \mapsto & \begin{cases} \alpha(a + 2t(b-a)), & \text{if } t \in \left[0, \frac{1}{2}\right] \\ \beta(c + (2t-1)(d-c)), & \text{if } t \in \left(\frac{1}{2}, 1\right]. \end{cases} \end{array}$$

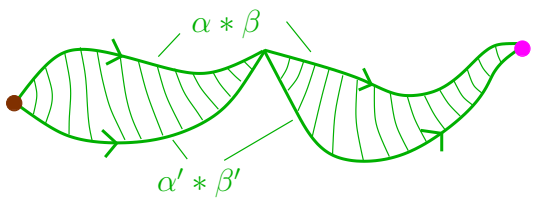
The concatenation of two paths is thus given by "first running along α" and then "running along β". Here we reparametrized the path so that the domain of $\alpha * \beta$ is $[0,1]$. This convention might look slightly odd, but later on we will mostly work with paths that are defined on the interval $[0,1]$.

Lemma 47.4. Let $\alpha, \alpha'\colon [a,b] \to X$ and $\beta, \beta'\colon [c,d] \to X$ be two pairs of paths in a topological space X such that $\alpha(b) = \alpha'(b) = \beta(c) = \beta'(c)$. Then



$$\alpha \simeq \alpha' \text{ and } \beta \simeq \beta' \quad \Longrightarrow \quad \alpha * \beta \simeq \alpha' * \beta'.$$

Put differently, if $[\alpha] = [\alpha']$ and $[\beta] = [\beta']$, then $[\alpha * \beta] = [\alpha' * \beta']$.



Proof. We leave it to the reader to provide the fairly elementary proof. ■

[451] Note that φ is not required to be a homeomorphism.

[452] Where do we actually use the hypothesis that $\varphi(a) = a$ and $\varphi(b) = b$?

α is path-homotopic to α'
and β is path-homotopic to β'

then $\alpha * \beta$ is path-homotopic to $\alpha' * \beta'$

Definition. Let $[\alpha]$ and $[\beta]$ be two equivalence classes of paths in a topological space X with $\alpha(1) = \beta(0)$. We define the[453] product of the equivalence classes $[\alpha]$ and $[\beta]$ as

$$[\alpha] \cdot [\beta] \;:=\; [\alpha * \beta].$$

The following proposition says that the product of equivalence classes of paths shares many properties of the product structure of a group.

Proposition 47.5. (Path-Homotopy Concatenation Proposition) Let $\alpha, \beta, \gamma\colon [0,1] \to X$ be three paths in a topological space X. Then the following hold:

(1) If $\alpha(1) = \beta(0)$ and $\beta(1) = \gamma(0)$, then[454]

$$[\alpha] \cdot ([\beta] \cdot [\gamma]) \;=\; ([\alpha] \cdot [\beta]) \cdot [\gamma].$$

(2) For $x \in X$ we denote by e_x the constant path that is given by $e_x(t) := x$, $t \in [0,1]$. Then the following equality holds

$$[e_{\alpha(0)}] \cdot [\alpha] \;=\; [\alpha] \;=\; [\alpha] \cdot [e_{\alpha(1)}].$$

(3) We denote by $\overline{\alpha}$ the inverse path. Then the following equalities hold

$$[\alpha] \cdot [\overline{\alpha}] \;=\; [e_{\alpha(0)}] \quad \text{and} \quad [\overline{\alpha}] \cdot [\alpha] \;=\; [e_{\alpha(1)}].$$

Proof. Let $\alpha, \beta, \gamma\colon [0,1] \to X$ be three paths in a topological space X.

(1) Suppose that $\alpha(1) = \beta(0)$ and $\beta(1) = \gamma(0)$. We need to show that

$$\alpha * (\beta * \gamma) \;\simeq\; (\alpha * \beta) * \gamma.$$

We consider the map

$$\begin{aligned} \Phi\colon [0,1] &\to X \\ t &\mapsto \begin{cases} \alpha(3t), & \text{if } t \in [0, \tfrac{1}{3}], \\ \beta(3t-1), & \text{if } t \in [\tfrac{1}{3}, \tfrac{2}{3}], \\ \gamma(3t-2), & \text{if } t \in [\tfrac{2}{3}, 1]. \end{cases} \end{aligned}$$

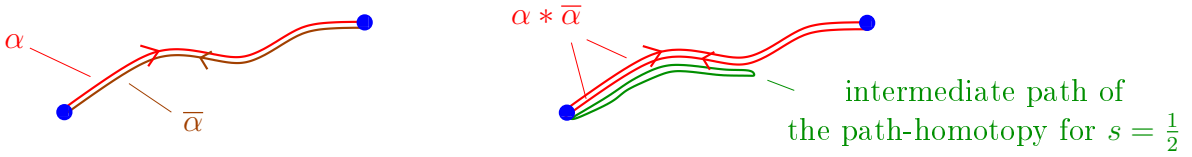
It follows from our hypothesis and Pasting Proposition 2.6 (2) that this map is indeed continuous. We consider the maps

$$\begin{aligned} p\colon [0,1] &\to [0,1] \\ t &\mapsto \begin{cases} \tfrac{2}{3}t, & \text{if } t \in [0, \tfrac{1}{2}], \\ \tfrac{4}{3}t - \tfrac{1}{3}, & \text{if } t \in (\tfrac{1}{2}, 1] \end{cases} \end{aligned} \quad \text{and} \quad \begin{aligned} q\colon [0,1] &\to [0,1] \\ t &\mapsto \begin{cases} \tfrac{4}{3}t, & \text{if } t \in [0, \tfrac{1}{2}], \\ \tfrac{2}{3}t + \tfrac{1}{3}, & \text{if } t \in (\tfrac{1}{2}, 1] \end{cases} \end{aligned}$$

[453] According to Lemma 47.4 this definition does not depend on the choice of the representatives α and β of the equivalence classes.

[454] Put differently, the paths $\alpha * (\beta * \gamma)$ and $(\alpha * \beta) * \gamma$ are path-homotopic. Note that these paths are similar in the sense that both paths "run through" the points on α, β and γ, but at different speeds. In general the paths are not equal, for example we have $(\alpha * (\beta * \gamma))(\frac{1}{2}) = \alpha(1)$ and $((\alpha * \beta) * \gamma)(\frac{1}{2}) = \beta(1)$.

Then
$$\alpha * (\beta * \gamma) \underset{\text{by definition}}{=} \Phi \circ p \underset{\text{by Lemma 47.3}}{\simeq} \Phi \simeq \Phi \circ q \underset{\text{by definition}}{=} (\alpha * \beta) * \gamma$$



(2) We consider the map
$$\begin{aligned} q\colon [0,1] &\to [0,1] \\ t &\mapsto \begin{cases} 0, & \text{if } t \in [0, \frac{1}{2}], \\ 2t-1, & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{aligned}$$

Then
$$e_{\alpha(0)} * \alpha \underset{\text{by definition}}{=} \alpha \circ q \underset{\text{by Lemma 47.3}}{\simeq} \alpha.$$

This shows that $[e_{\alpha(0)}] \cdot [\alpha] = [e_{\alpha(0)} * \alpha] = [\alpha]$. Almost the same argument also implies that $[\alpha] = [\alpha] \cdot [e_{\alpha(1)}]$.

(3) We write $P = \alpha(0)$. Note that $\alpha * \overline{\alpha}$ is a loop in P. We consider the map
$$\begin{aligned} F\colon [0,1] \times [0,1] &\to X \\ (t,s) &\mapsto \begin{cases} \alpha(2t \cdot s), & \text{if } t \in [0, \frac{1}{2}], \\ \alpha(2s - 2t \cdot s), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{aligned}$$

It follows from the Homotopy Stacking Lemma 14.3 that this map is indeed continuous. For $s = 0$ we obtain the constant path at P and for $s = 1$ we obtain the path $\alpha * \overline{\alpha}$. For any $s \in [0,1]$ we furthermore have $F(0,s) = F(1,s) = P$. Thus F is a path-homotopy from the constant path to $\alpha * \overline{\alpha}$ which implies that $[e_{\alpha(0)}] = [\alpha * \overline{\alpha}] = [\alpha] \cdot [\overline{\alpha}]$. Almost the same argument shows that $[\overline{\alpha} * \alpha] = [e_{\alpha(1)}]$. ■

47.2. **The fundamental group of a pointed topological space.** In the Path-Homotopy Concatenation Proposition 47.5 we saw that the concatenation of path-homotopy classes of paths shares many properties of the multiplication in a group. Nonetheless the path-homotopy classes of paths do not form a group, since the concatenation of two paths is not defined, unless the endpoint of the first path agrees with the starting point of the second path.
We will resolve this problem by restricting our attention to loops.

Definition. Let X be a topological space and let $x_0 \in X$ be a point. A loop in (X, x_0) is a path $f\colon [0,1] \to X$[455] with $f(0) = f(1) = x_0$, i.e. x_0 is the starting as well as the endpoint of f.

Proposition 47.6. Let X be a topological space and $x_0 \in X$. The set
$$\pi_1(X, x_0) := \{\text{path-homotopy classes of loops in } (X, x_0)\}$$
together with the product map $[\alpha] \cdot [\beta] := [\alpha * \beta]$ forms a group where the neutral element is represented by the constant path at x_0 and where the inverse of $[\gamma]$ is given by $[\overline{\gamma}]$.

[455] Note that part of the definition of "loop in (X, x_0)" is that the domain is the interval $[0,1]$.

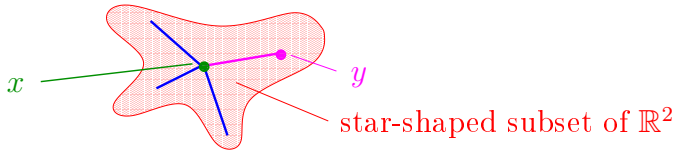
Proof. It is clear that the concatenation of any two loops in (X, x_0) is defined. According to Lemma 47.4 the concatenation of paths descends to a well-defined map

$$\begin{array}{rcl} \pi_1(X,x_0) \times \pi_1(X,x_0) & \to & \pi_1(X,x_0) \\ ([\alpha],[\beta]) & \mapsto & [\alpha]\cdot[\beta] := [\alpha * \beta]. \end{array}$$

According to the Path-Homotopy Concatenation Proposition 47.5 (1) this product map satisfies the associativity axiom. The trivial element is according to the Path-Homotopy Concatenation Proposition 47.5 (2) given by the path-homotopy class of the constant loop $[e_{x_0}]$. Furthermore according to the Path-Homotopy Concatenation Proposition 47.5 (3) the inverse of the path-homotopy class of a loop $\gamma\colon [0,1] \to X$ in x_0 is given by the path-homotopy class of the loop defined by $\overline{\gamma}(t) := \gamma(1-t)$, $t \in [0,1]$. ■

Definition. We call $\pi_1(X, x_0)$ the fundamental group of X with respect to the base point x_0.

One of our main goals in the intermediate future will be to determine the fundamental group of the topological spaces that we introduced in the earlier sections.



Examples.

(1) Let X be a convex subset of $\mathbb{R}^n$ and let $x_0 \in \mathbb{R}^n$ be an arbitrary point. As we pointed out on page 1048, all loops in (X, x_0) are null-homotopic. More precisely, if $\gamma\colon [0,1] \to \mathbb{R}^n$ is a loop in $(\mathbb{R}^n, x_0)$, then

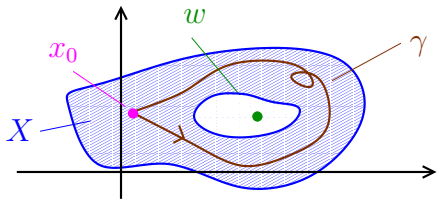
$$\begin{array}{rcl} F\colon [0,1]\times[0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \gamma(t)\cdot(1-s) + x_0 \cdot s \end{array}$$

is a path-homotopy between the loop γ and the constant loop e_{x_0}. Thus it follows that $\pi_1(X, x_0) = 0$.[456]

(2) We say that a subset $X \subset \mathbb{R}^n$ is *star-shaped* if there exists an $x \in X$ such that for all $y \in X$ the segment $\{xt + y(1-t) \,|\, t \in [0,1]\}$ lies in X. For example open and closed balls and open and closed rectangles are star-shaped. Furthermore all convex subsets are star-shaped. Precisely the same proof as in (1) shows that the $\pi_1(X, x) = 0$.

Next we state the following theorem from complex analysis.

[456] If $\pi_1(X, x_0)$ is the trivial group, then we usually write $\pi_1(X, x_0) = 0$. This notation is commonly used, even though it is not entirely logical: we use the multiplicative notation for the product structure on the group $\pi_1(X, x_0)$, and it would therefore make more sense to write $\pi_1(X, x_0) = 1$ if the group $\pi_1(X, x_0)$ is trivial.



Theorem 47.7. Let X be a proper subset[457] of $\mathbb{C}$, let $x_0 \in X$ be a point and let $w \in \mathbb{C}\setminus X$ be a point in the complement of X. The map

$$\begin{array}{rcl} \pi_1(X, x_0) & \to & \mathbb{Z} \\ [\gamma] & \mapsto & \frac{1}{2\pi \mathrm{i}} \int\limits_{\gamma} \frac{1}{z-w}\, dz \end{array}$$

is a well-defined homomorphism.

Remark. As in the case of Corollary 46.1, we do not really need Theorem 47.7 and its subsequent Corollary 47.8. If one has seen complex analysis, or if one is willing to take Theorem 47.7 on face value, it allows us to show that some fundamental groups are non-trivial, before we have developed the full machinery for calculating fundamental groups. But eventually we will supplant Corollary 47.8 by a much stronger statement proved using purely topological methods.

Proof. A vigilant reader might first have noticed that the statement of Theorem 47.7 contains a slight cheat. We use the path integral over a continuous path γ, whereas so far on page 791 we gave only the definition for the integral over a smooth path. The more general definition of a path integral is given in [**Lang1999**, Chapter III.4]. The fact that the given integral takes values in $\mathbb{Z}$ is proved in [**Lang1999**, Lemma IV.4.1]. Furthermore the fact that this integral defines a well-defined map on the fundamental group is a consequence of [**Lang1999**, Theorem III.5.1]. Finally it follows almost immediately from the definitions that the given map is a homomorphism. ■

the map

$$\begin{array}{rcl} \pi_1(X, x_0) & \to & \mathbb{Z} \\ [\gamma] & \mapsto & \frac{1}{2\pi \mathrm{i}} \int\limits_{\gamma} \frac{1}{z-w}\, dz \end{array}$$

is a homomorphism

The previous example together with Theorem 47.7 give us the following neat corollary.

Corollary 47.8. There exists an epimorphism $\pi_1(S^1, 1) \to \mathbb{Z}$.

Proof. The corollary follows from Theorem 47.7 and the calculation on page 791. ■

This raises the following question.

Question 47.9. Is the above epimorphism $\pi_1(S^1, 1) \to \mathbb{Z}$ in fact an isomorphism?

The definition of the fundamental group of a topological space X relies on the choice of a base point x_0. The following proposition shows that, at least for path-connected topological spaces, the choice of the base point does not affect the isomorphism type of the fundamental group.

Proposition 47.10. (Change-of-Base Point Proposition) Let X be a topological space, let x_0 and x_1 be two points in X and let $p\colon [0,1] \to X$ be a path from x_0 to x_1. Then the following five statements hold:

(1) The map

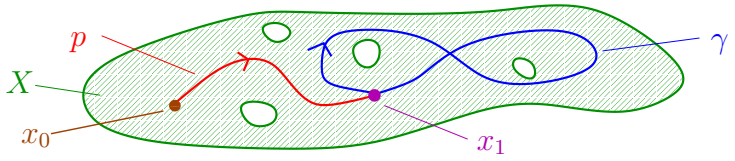
[457] We say A is a proper subset of B if $A \subset B$ and if $A \neq B$.

$$\begin{array}{rcl} p_*\colon \pi_1(X,x_1) & \to & \pi_1(X,x_0) \\ [\gamma] & \mapsto & [p*\gamma*\overline{p}] \end{array}$$

is well-defined and it is a group isomorphism.

(2) If $x_0 = x_1$, then the map p_* is just conjugation by $[p] \in \pi_1(X,x_0)$, i.e. for any $g \in \pi_1(X,x_0) = \pi_1(X,x_1)$ we have

$$p_*(g) \;=\; [p]\cdot g\cdot [p]^{-1} \;\in\; \pi_1(X,x_0).$$



(3) If $q\colon [0,1] \to X$ is a path from x_1 to another point x_2, then

$$(p*q)_* \;=\; p_*\circ q_*\colon \pi_1(X,x_2) \;\to\; \pi_1(X,x_0).$$

(4) If $\pi_1(X,x_0)$ is abelian, then for any two paths $p,q\colon [0,1]\to X$ from x_0 to x_1 we have $p_* = q_*\colon \pi_1(X,x_1)\to\pi_1(X,x_0)$.

(5) If $f\colon X \to Y$ is a map to another topological space, then the following diagram commutes:

$$\begin{array}{ccc} \pi_1(X,x_0) & \xrightarrow{\;p_*\;} & \pi_1(X,x_1) \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \pi_1(Y,f(x_0)) & \xrightarrow{\;(f\circ p)_*\;} & \pi_1(Y,f(x_1)). \end{array}$$

Proof. Let X be a topological space and let x_0 and x_1 be two points in X that are connected via a path $p\colon [0,1]\to X$ from x_0 to x_1.

(1) Let γ be a loop in (X,x_1). Then $p*\gamma*\overline{p}$ is evidently a loop in (X,x_0). From Lemma 47.4 and the Path-Homotopy Concatenation Proposition 47.5 it follows that the path-homotopy class of $p*\gamma*\overline{p}$ depends only on the choice of the path-homotopy class of γ, i.e. the map

$$\begin{array}{rcl} \Phi\colon \pi_1(X,x_1) & \to & \pi_1(X,x_0) \\ [\gamma] & \mapsto & [p*\gamma*\overline{p}] \end{array}$$

is well-defined. Furthermore for two loops γ,δ in (X,x_1) we have

$$\begin{array}{rcl} \Phi([\gamma])*\Phi([\delta]) & = & [p*\gamma*\overline{p}]*[p*\delta*\overline{p}] \\ & = & [p*\gamma*e_{x_1}*\delta*\overline{p}] \\ & & \uparrow \\ & & \text{Path-Homotopy Concatenation Proposition 47.5 (3) and Lemma 47.4} \end{array} \qquad \begin{array}{rcl} & = & [p*\gamma*\overline{p}*p*\delta*\overline{p}] \\ & = & [p*(\gamma*\delta)*\overline{p}] \;=\; \Phi([\gamma*\delta]). \\ & & \uparrow \\ & & \text{Path-Homotopy Concatenation Proposition 47.5 (} \end{array}$$

Thus we have shown that Φ is a group homomorphism. Furthermore Φ is even a group isomorphism, since an inverse map is given by[458]

$$\begin{array}{rcl} \Psi\colon \pi_1(X,x_0) & \to & \pi_1(X,x_1) \\ [\delta] & \mapsto & [\overline{p}*\delta*p]. \end{array}$$

(2),(3) These two statements follow basically immediately from the definitions.

(4) This statement is a straightforward consequence of (1), (2) and (3). We will provide the proof in Exercise 47.3.

[458] Why is $\Phi\circ\Psi$ the identity on $\pi_1(X,x_0)$ and why is $\Psi\circ\Phi$ the identity on $\pi_1(X,x_1)$?

(5) This statement again follows immediately from the definitions. ■

We obtain the following corollary:

Corollary 47.11. (Base Point Independence Corollary) Let X be a path-connected topological space and let $x_0, x_1 \in X$. Then the groups $\pi_1(X, x_0)$ and $\pi_1(X, x_1)$ are isomorphic.

Example. Let X be a star-shaped subset of $\mathbb{R}^n$. Above we saw that there exists an $x \in X$ such that $\pi_1(X, x) = 0$. It now follows from the Base Point Independence Corollary 47.11 that $\pi_1(X, y) = 0$ for any point $y \in X$. Put differently, the fundamental group of every star-shaped subset of $\mathbb{R}^n$ with respect to any base point is trivial.

If X is a path-connected topological space, then the Base Point Independence Corollary 47.11 states that the isomorphism type of the fundamental group does not depend on the choice of the base point. Sometimes we suppress the base point from the notation and we denote by $\pi_1(X)$ the isomorphism type of the fundamental group.

Definition. Let X be a non-empty path-connected topological space. If $\pi_1(X) = 0$[459], then we say that X is simply connected.[460]

Lemma 47.12. Let X be a topological space and let P, Q be two points in X. If X is simply connected, then any two paths from P to Q are path-homotopic.

Proof. The proof is precisely the content of Exercise 47.2. ■

We already saw on page 1055 that $\mathbb{R}^n$ and more generally, all star-shaped subsets of $\mathbb{R}^n$ are simply connected. The following statement is much more interesting:

Proposition 47.13. (Sphere-π_1-Proposition) For any $n \geq 2$ the sphere S^n is simply connected.

In the proof of the Sphere-π_1-Proposition 47.13 we will need the following lemma.

Lemma 47.14. For any $P \in S^n$ the topological space $S^n \setminus \{P\}$ is simply connected.

Proof of Lemma 47.14. Recall that in Lemma 2.18 we showed that there exists a homeomorphism $f\colon S^n \to \mathbb{R}^n \cup \{\infty\}$. We set $Q := f^{-1}(\infty)$. Thus f restricts to homeomorphism $f\colon S^n \setminus \{Q\} \to \mathbb{R}^n$. Now let P be any other point on S^n. There exists a homeomorphism[461] $g\colon S^n \to S^n$ with $g(P) = Q$. Then $f \circ g\colon S^n \to \mathbb{R}^n \cup \{\infty\}$ restricts to a homeomorphism $S^n \setminus \{P\} \to \mathbb{R}^n$. But $\mathbb{R}^n$ is simply connected, hence $S^n \setminus \{P\}$ is also simply connected. ■

Now we can turn to the proof of the Sphere-π_1-Proposition 47.13.

Here is a very short "proof": Let $x_0 \in S^n$ and let $\gamma\colon [0,1] \to S^n$ be a loop in x_0. We have to show that γ is null-homotopic. We pick a point P that does not lie in the image of γ. By Lemma 47.14 the topological space $S^n \setminus \{P\}$ is simply connected, hence γ is null-homotopic in $S^n \setminus \{P\}$, in particular it is null-homotopic in S^n.

[459] Since X is a path-connected topological space it is irrelevant which base point we consider.

[460] It is straightforward to see that for subsets of $\mathbb{C}$ we obtain the same notion of "simply connectedness" as on page 1045.

[461] The existence of the homeomorphism follows from Proposition 36.4. But one can also easily give an elementary proof of that fact. More precisely, using basic facts from linear algebra one can show that there exists an orthogonal matrix A with $A \cdot P = Q$. Then the map $g\colon S^n \to S^n$ that is given by multiplication by A has the desired property.

This sounds convincing, except for one crucial gap: we did not justify why there exists a point P that does not lie in the image of γ. In fact, as we saw in the Space-Filling Curve Theorem 6.13, such a point does not need to exist since there are surjective maps from an interval to any S^n.

We provide two approaches to fixing this problem. The first approach uses the Whitney Approximation Theorem 29.1. The second approach is completely self-contained and considerably longer.

First proof of the Sphere-π_1-Proposition 47.13. Let $n \geq 2$, let $x_0 \in S^n$ and let $\gamma\colon [0,1] \to S^n$ be a loop in x_0. It follows immediately from the Whitney Approximation Theorem 29.1, applied to the closed set[462] $A = \{0,1\} \subset [0,1]$, that there exists a homotopy rel $\{0,1\}$ from $\gamma\colon [0,1] \to S^n$ to a smooth map $\delta\colon [0,1] \to S^n$ with $\delta(0) = \delta(1) = x_0$. It follows from the Measure-Zero Properties Proposition 30.2 and 30.3 and the hypothesis that $n \geq 2$ that the smooth map $\delta\colon [0,1] \to S^n$ is not surjective. We pick $P \in S^n \setminus \{P\}$. By Lemma 47.14 we know that δ is homotopic rel $\{0,1\}$ to the constant map. Thus γ is also homotopic rel $\{0,1\}$ to the constant map. We have thus shown that δ represents the trivial element in $\pi_1(S^n, x_0)$. ■

Second proof of the Sphere-π_1-Proposition 47.13. Let $n \geq 2$. We write

$$\begin{array}{lllllllll} & N & := & (0,\dots,0,1) & \text{“North Pole”} & \text{and} & U & := & S^n \setminus \{N\}, \\ \text{and also} & S & := & (0,\dots,0,-1) & \text{South Pole} & \text{and} & V & := & S^n \setminus \{S\}. \end{array}$$

We fix a base point x_0 on S^n that is neither N nor S. By Lemma 47.14 it suffices to show that any loop in (S^n, x_0) is path-homotopic to a loop in $U = S^n \setminus \{N\}$.

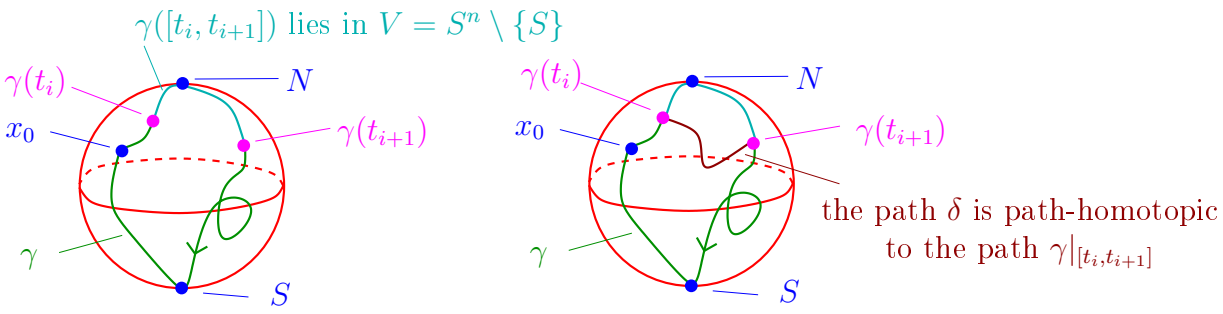
So let γ be a loop in (S^n, x_0).

Claim. There exists a subdivision

$$0 = t_0 < t_1 < \ldots < t_{k-1} < t_k = 1,$$

such that the following hold:

(1) for each $i \in \{0,\dots,k-1\}$ we have $\gamma([t_i, t_{i+1}]) \subset U$ or $\gamma([t_i, t_{i+1}]) \subset V$, and
(2) for each $i \in \{1,\dots,k-1\}$ we have $\gamma(t_i) \neq N$ and $\gamma(t_i) \neq S$.



Proof. By the Lebesgue Corollary 6.6 applied to $\gamma\colon [0,1] \to S^n$ and $S^n = U \cup V$ there exists a k such that for any $i \in \{0,\dots,k-1\}$ the image $\gamma([\frac{i}{k}, \frac{i+1}{k}])$ lies in U or in V. In particular the subdivision $t_i = \frac{i}{k}$, $i = 0,\dots,k$ satisfies condition (1).

Now suppose that there exists an $i \in \{1,\dots,k-1\}$ with $\gamma(t_i) = N$. Then neither $\gamma([t_{i-1}, t_i])$ nor $\gamma([t_i, t_{i+1}])$ can be contained in $U = S^n \setminus \{N\}$. So by (1) both have to be contained in V, in particular we have $\gamma([t_{i-1}, t_{i+1}]) \subset V$. But then we can remove t_i from the subdivision. Iterating this process we can assume that for each every i we have $\gamma(t_i) \neq N$. Similarly we can arrange for every i we have $\gamma(t_i) \neq S$. ⊞

As mentioned before, by Lemma 47.14 it now suffices to prove the following claim.

Claim. The loop $\gamma\colon [0,1] \to S^n$ in (S^n, x_0) is path-homotopic to a path that does not hit the North Pole N.

[462] We use the observation that it follows immediately from the definition on page 549 that the restriction of any map $[0,1] \to M$ to a smooth manifold is smooth on the subset $\{0,1\}$.

Proof. We pick a subdivision as in the previous claim. Suppose there exists an $i \in \{0, \ldots, k-1\}$ such that $\gamma([t_i, t_{i+1}])$ hits N. By the choice of our subdivision we know that $\gamma([t_i, t_{i+1}])$ lies entirely in $V = S^n \setminus \{S\}$.[463] Since $S^n \setminus \{N, S\}$ is path-connected and since $\gamma(t_i) \neq N, S$, $\gamma(t_{i+1}) \neq N, S$ we can pick a path $\delta\colon [t_i, t_{i+1}] \to U \cap V = S^n \setminus \{N, S\}$ that connects $\gamma(t_i)$ and $\gamma(t_{i+1})$. Since the paths $\gamma|_{[t_i,t_{i+1}]}$ and δ both lie in the simply connected set $V = S^n \setminus \{S\}$ they are path-homotopic by Lemma 47.12. In the loop γ we now replace $\gamma([t_i, t_{i+1}])$ by δ. We obtain a new loop that is path-homotopic to the original loop and that does not hit N on the interval $[t_i, t_{i+1}]$. Iterating this procedure gives us the desired path-homotopy to a loop that does not hit N.[464] ∎

47.3. The fundamental group as functor.

Definition. Let $f\colon X \to Y$ be a map between topological spaces and let $x_0 \in X$ be a base point. If $\gamma\colon [0,1] \to X$ is a loop in the point x_0, then $f \circ \gamma\colon [0,1] \to Y$ is a loop in the point $f(x_0)$. It is straightforward to see that

$$\begin{array}{rcl} f_*\colon \pi_1(X, x_0) & \to & \pi_1(Y, f(x_0)) \\ [\gamma] & \mapsto & [f \circ \gamma] \end{array}$$

is a well-defined map, i.e. $f_*([\gamma])$ is independent of the choice of the representative of the path-homotopy class.[465] Furthermore it follows easily from the definitions[466] that f_* is a group homomorphism. We call f_* the induced map. It also follows easily from the definitions that

$$\begin{array}{rcll} (\mathrm{id}_X)_* & = & \mathrm{id}_{\pi_1(X,x_0)}, & \text{for all pointed pairs } (X, x_0), \\ (g \circ f)_* & = & g_* \circ f_*, & \text{for all maps } f\colon (X, x_0) \to (Y, y_0) \text{ and } g\colon (Y, y_0) \to (Z, z_0). \end{array}$$

The above description of the properties of the induced maps look very much like the properties of a covariant functor. We just need to figure out what the categories are supposed to be. This leads us to the following definition.

[463] We know it lies in U or V, but since it hits N it cannot lie in U.

[464] Where did we use in the proof that $n \geq 2$?

[465] Indeed, suppose that γ and δ are two loops in (X, x_0) that are path-homotopic. Let F be a path-homotopy between γ and δ. Then $f \circ F$ is a path-homotopy between $f \circ \gamma$ and $f \circ \delta$. We had used almost the same argument on page 1049.

[466] If γ and δ are loops in x_0, then it follows immediately from the definitions that $(f \circ \gamma) * (f \circ \delta) = f \circ (\gamma * \delta)$.

Definition. A pointed topological space is a pair (X, x_0), where X is a topological space and x_0 is a point in X. We refer to the category $\mathcal{PTop}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{PTop}) &:= \text{all pointed topological spaces,} \\ \mathrm{Mor}((X,x_0),(Y,y_0)) &:= \text{all continuous maps } f \text{ from } X \text{ to } Y \text{ with } f(x_0) = y_0 \end{aligned}$$

with the usual composition of maps as the category of pointed topological spaces.

Summarizing we just convinced ourselves of the validity of the following proposition.

Proposition 47.15. Let $\mathcal{PTop}$ be the category of pointed topological spaces and let $\mathcal{Group}$ be the category of groups. Then the map

$$\begin{aligned} \mathrm{Ob}(\mathcal{PTop}) &\to \mathrm{Ob}(\mathcal{Group}) \\ (X,x_0) &\mapsto \pi_1(X,x_0) \end{aligned}$$

together with the maps

$$\begin{aligned} \mathrm{Mor}((X,x_0),(Y,y_0)) &\to \mathrm{Mor}(\pi_1(X,x_0),\pi_1(Y,y_0)) \\ (f\colon (X,x_0)\to(Y,y_0)) &\mapsto \left(\begin{array}{rcl} f_*\colon \pi_1(X,x_0) & \to & \pi_1(Y,y_0) \\ [\gamma] & \mapsto & [f\circ\gamma] \end{array} \right) \end{aligned}$$

is a covariant functor.

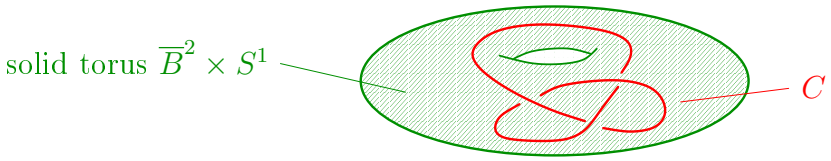
Next we will see that the functoriality of the fundamental groups can be helpful for studying certain questions. Let us recall the following definition from page 433.

Definition. Let X be a topological space and let $A \subset X$ be a subspace. We say A is a retract of X if there exists a retraction $r\colon X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

Examples.

(1) Let X be a topological space. Then any point $x_0 \in X$ is a retract of X, indeed, the map $r(x) = x_0$ for $x \in X$ is a retraction.

(2) The circle $S^1 \times \{1\}$ is a retract of the torus $S^1 \times S^1$, in fact a retraction is given by $r(z,w) = (z,1)$.

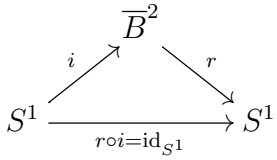


(3) The circle S^1 is a retract of $\overline{B}^2 \setminus \{(0,0)\}$, indeed, the map

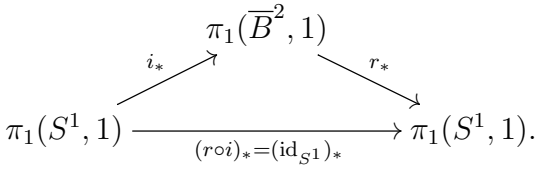
$$\begin{aligned} \overline{B}^2 \setminus \{(0,0)\} &\to S^1 \\ z &\mapsto \tfrac{z}{|z|} \end{aligned}$$

is a retraction. (Here we consider $\overline{B}^2$ as subset of $\mathbb{C}$.)

(4) The set $S^0 = \{-1,1\}$ is not a retract of $\overline{B}^1 = [-1,1]$. Indeed, since $[-1,1]$ is connected and since S^0 is discrete it follows from the Connected-to-Discrete Lemma 2.27 that any map from $[-1,1]$ to S^0 has to be constant. Thus there does not exist a map $f\colon [-1,1] \to S^0$ with $f(-1) = -1$ and $f(1) = 1$.



(5) Finally we consider the knotted curve C in the solid torus $\overline{B}^2 \times S^1$ that is shown in the figure below. We invite the reader to think about the question whether or not C is a retract of $\overline{B}^2 \times S^1$. We will answer the question in Section 162.1.



Now we can push the second-to-last example up by one dimension.

Lemma 47.16. The circle S^1 is not a retract of $\overline{B}^2$.

Proof. We denote by $i\colon S^1 \to \overline{B}^2$ the inclusion map. Suppose there exists a retraction $r\colon \overline{B}^2 \to S^1$. By definition this means that $r \circ i = \mathrm{id}_{S^1}$. We obtain the following commutative diagram of maps between topological spaces

which induces

It follows from the functoriality of fundamental groups that $r_* \circ i_* = (r \circ i)_*$, i.e. the diagram on the right-hand side commutes. By the functoriality we know that $(\mathrm{id}_{S^1})_*$ is the identity of $\pi_1(S^1, 1)$.

We saw on page 1058 that $\pi_1(\overline{B}^2, 1)$ is the trivial group whereas we saw in Corollary 47.8 that $\pi_1(S^1, 1)$ is not the trivial group. The lower horizontal map in the second diagram is thus an isomorphism of a non-trivial group, but the upper map factors through the trivial group, i.e. the composition of i_* and r_* cannot be an isomorphism of a non-trivial group.[467] Thus we have obtained a contradiction. ■

The last example and the last lemma now raise the following question.

Question 47.17. Let $n \geq 2$. Is S^n a retract of $\overline{B}^{n+1}$?

At the moment we cannot answer this question. We will first need to develop new invariants before we can return to this question. We will not be able to answer this question for many months.

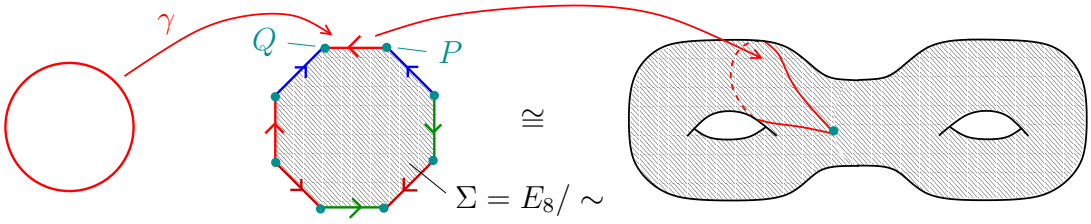
Lemma 47.18. Let X be a topological space and let $A \subset X$ be a retract of X. Let $a \in A$. We denote by $i\colon A \to X$ the inclusion map.

(1) There exists an epimorphism $\varphi\colon \pi_1(X, a) \to \pi_1(A, a)$ such that $\varphi \circ i_*$ is the identity on $\pi_1(A, a)$.
(2) The inclusion induced map $\pi_1(A, a) \to \pi_1(X, a)$ is a monomorphism.

Proof. Almost exactly the same argument as in the proof of Lemma 47.16 also provides a proof of the lemma. We will fill in the details in Exercise 47.8. ■

Example. We had just seen on page 1061 that the circle $S^1 \times \{1\}$ is a retract of the torus $S^1 \times S^1$. Furthermore we saw in Corollary 47.8 that $\pi_1(S^1, 1)$ is not the trivial group. It follows from Lemma 47.18 that the fundamental group of the torus is also non-trivial. In the Sphere-π_1-Proposition 47.13 we saw that $\pi_1(S^2) = 0$. Thus we see that the torus $S^1 \times S^1$ and the sphere S^2 are not homeomorphic.

[467] Why not?



Lemma 47.19. Let E_8 be the regular octagon from the definition of the surface of genus 2, see page 265 for details, and let $\Sigma = E_8/\sim$ be the surface of genus 2. Let P and Q be two adjacent vertices of E_8. Then the following hold:

(1) The map
$$\begin{array}{rcl} \gamma\colon S^1 & \to & E_8/\sim \\ \exp(2\pi i t) & \mapsto & [t\cdot P + (1-t)\cdot Q] \end{array}$$
is an embedding.

(2) There exists a map $\Phi\colon E_8/\sim \to S^1 \times S^1$ such that the following diagram commutes
$$\begin{array}{ccc} & S^1 & \\ {\scriptstyle\gamma}\swarrow & & \searrow{\scriptstyle z\mapsto(z,1)} \\ E_8/\sim & \xrightarrow{\Phi} & S^1\times S^1. \end{array}$$

(3) The subset $\gamma(S^1)$ is a retract of $\Sigma = E_8/\sim$.

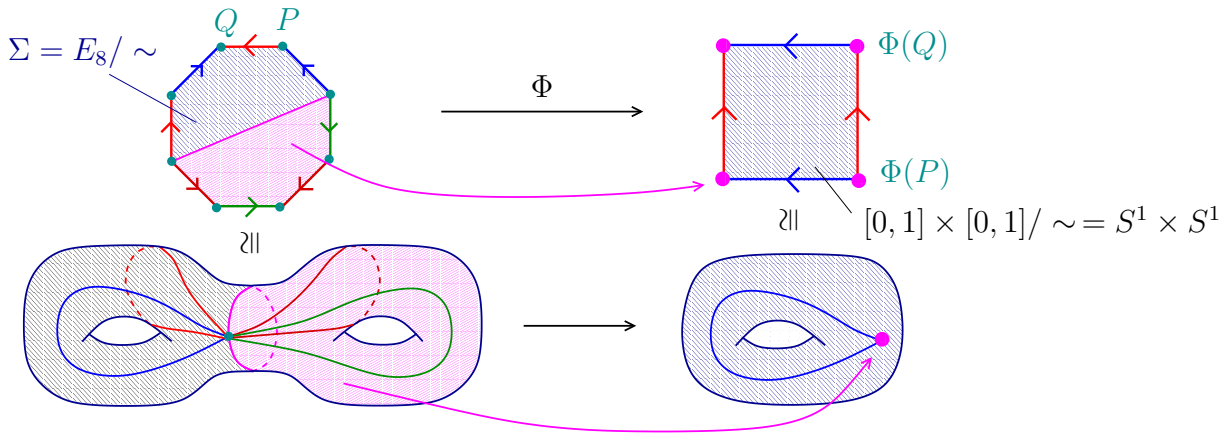
(4) There exists an epimorphism $\pi_1(\Sigma, P) \to \mathbb{Z}$ that sends $[\gamma]$ onto 1.[468]

Remark. The lemma shows in particular that the four loops that we drew in the figure on 266 on the surface of genus 2 represent non-trivial elements in the fundamental group. Almost the same way one can show that in the surface of genus g, $g \geq 2$, defined as a quotient of a regular $4g$-gon, each edge gives rise to a non-trivial element of the fundamental group.

Proof.

(1) It is clear that γ is continuous and injective. By the Surface-is-Topological Manifold Proposition 18.7 we know that $\Sigma = E_8/\sim$ is Hausdorff. It follows from the Compact-Hausdorff Proposition 2.17 (2) that γ is a closed embedding.

(2) The map Φ is sketched in the figure below on the top. It is given by sending all points in the lower pentagon to a single point, such a map can be extended continuously to the upper pentagon in such a way that the remaining four sides of the upper



[468] Recall that by the bijection on page 1050 we view maps $f\colon S^1 \to \Sigma$ with $f(1) = P$ as elements in $\pi_1(\Sigma, P)$.

pentagon get sent homeomorphically to the four sides of the square.[469] [470] This map Φ has the desired property.

(3) The retraction is now given by the concatenation of the maps

$$\Sigma \xrightarrow{\Phi} S^1 \times S^1 \xrightarrow{(z,w)\mapsto z} S^1.$$

(4) This statement is a consequence of (3), Lemma 47.18 and Corollary 47.8. ■

In many applications we will want to know whether a given map between topological spaces induces an isomorphism of fundamental groups. The following lemma says that in many settings the property of being an isomorphism is independent of the choice of base point.

Proposition 47.20. Let $\varphi\colon X \to Y$ be a map between topological spaces and let $x_0 \in X$.

(1) If $\gamma\colon [0,1] \to X$ is a path from x_0 to some point x_1, then the following diagram commutes[471]

$$\begin{array}{ccc} \pi_1(X,x_1) & \xrightarrow[\cong]{\gamma_*} & \pi_1(X,x_0) \\ {\scriptstyle\varphi_*}\downarrow & & \downarrow{\scriptstyle\varphi_*} \\ \pi_1(Y,\varphi(x_1)) & \xrightarrow[\cong]{(\varphi\circ\gamma)_*} & \pi_1(Y,\varphi(x_0)). \end{array}$$

(2) If $\varphi_*\colon \pi_1(X,x_0) \to \pi_1(Y,\varphi(x_0))$ is an isomorphism (epimorphism, monomorphism) for some base point $x_0 \in X$, then for any other base point x_1 in the same path component of X the map $\varphi_*\colon \pi_1(X,x_1) \to \pi_1(Y,\varphi(x_1))$ is also an isomorphism (epimorphism, monomorphism).

---

[469] It is clearly slightly painful to write down this map explicitly. It is easier to write down a similar map, which maps a square X onto a triangle Y in such a way that one side of the square gets sent to a vertex of the triangle and such that the remaining three sides of the square get sent to the three sides of the triangle. For example the map

$$\begin{array}{ccc} X := [0,1]\times[0,1] & \to & Y := \{(x,y) \in \mathbb{R}^2 \,|\, x \in [0,1], y \in [0,x]\} \\ (x,y) & \mapsto & (x,xy) \end{array}$$

is of that form.

[470] In the lower part of the above figure we illustrate the map for the surfaces viewed as subsets of $\mathbb{R}^3$. There the map Φ is given by crushing the right-hand half of the surface of genus 2 to a single point.

Proof.

(1) This statement follows immediately from the definitions.
(2) This statement follows from (1) and the fact that the horizontal maps are isomorphisms. ■

Exercises for Chapter 47.

Exercise 47.1. Consider the torus $T = S^1 \times S^1$ and consider the loop

$$\begin{array}{rcl} [0,1]/0 \sim 1 & \to & T = S^1 \times S^1 \\ t & \mapsto & (\exp(2\pi \mathrm{i} t), 1). \end{array}$$

Is the loop null-homotopic? If yes, provide a path-homotopy to a constant path. If not, show that the path is not null-homotopic.

Exercise 47.2. Let X be a topological space and let P, Q be two points in X. We suppose that X is simply connected. Show that any two paths from P to Q are path-homotopic.

Exercise 47.3. Let X be a topological space and let x_0 and x_1 be two points in X. Furthermore let $p, q\colon [0,1] \to X$ be two paths from x_0 to x_1. We suppose that $\pi_1(X, x_0)$ is abelian. Show that $p_* = q_*\colon \pi_1(X, x_1) \to \pi_1(X, x_0)$.

Exercise 47.4.

(a) Let $f\colon X \to Y$ be a surjective map of topological spaces and let $x \in X$. Is the induced map $f_*\colon \pi_1(X, x) \to \pi_1(Y, f(x))$ necessarily an epimorphism?
(b) Let $f\colon X \to Y$ be an injective map of topological spaces and let $x \in X$. Is the induced map $f_*\colon \pi_1(X, x) \to \pi_1(Y, f(x))$ necessarily a monomorphism?

Exercise 47.5. Given a group π we define its *automorphism group* $\mathrm{Aut}(\pi)$ as the group of all self-isomorphisms of π. We define the *inner automorphism group* as

$$\mathrm{Inn}(\pi) \;:=\; \{\varphi \in \mathrm{Aut}(\pi) \mid \text{ there exists an } h \in \pi \text{ such that } \varphi(g) = hgh^{-1} \text{ or all } g \in G\}.$$

One can easily verify that $\mathrm{Inn}(\pi)$ is a normal subgroup of $\mathrm{Aut}(\pi)$. Thus we can define the *outer automorphism group* to be the group

$$\mathrm{Out}(\pi) \;:=\; \mathrm{Aut}(\pi)/\mathrm{Inn}(\pi).$$

Now let X be a path-connected topological space, let $x_0 \in X$ and let $n \in \mathbb{N}$.

(a) Show that the map

$$\begin{array}{rcl} \Theta\colon \mathrm{Homeo}(X) & \to & \mathrm{Out}(\pi_1(X, x_0)) \\ (f\colon X \to X) & \mapsto & (\pi_1(X, x_0) \xrightarrow{f_*} \pi_1(X, f(x_0)) \xrightarrow[\uparrow]{\gamma_*} \pi_1(X, x_0)) \end{array}$$

pick any path γ from x_0 to $f(x_0)$ and consider the corresponding isomorphism given by the Change-of-Base Point Proposition 47.10

is well-defined, i.e. independent of the choice of the paths.
(b) Show that $\Theta\colon \mathrm{Homeo}(X) \to \mathrm{Out}(\pi_1(X, x_0))$ is a group homomorphism.

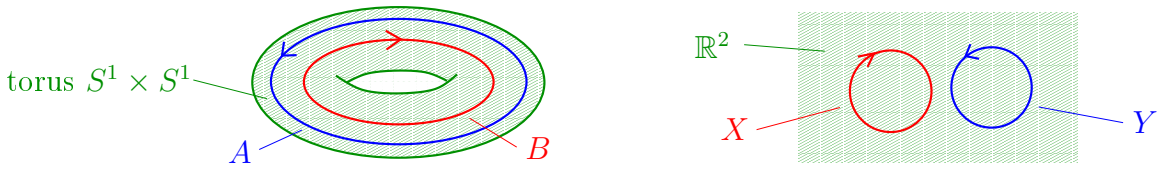
[472] Here the horizontal maps are the isomorphisms that we introduced in the Change-of-Base Point Proposition 47.10 (1).

Exercise 47.6. Show that $\pi_1(S^1 \times S^1)$ admits an epimorphism onto $\mathbb{Z}^2$.

Exercise 47.7. Show that there exists a homeomorphism of the torus $S^1 \times S^1$ that does not extend to a diffeomorphism of the solid torus $S^1 \times \overline{B}^2$.

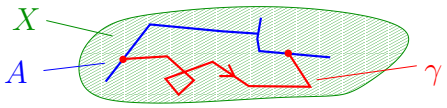
Exercise 47.8. Let $a \in A$. We denote by $i\colon A \to X$ the inclusion map.

(a) Show that there exists an epimorphism $\varphi\colon \pi_1(X, a) \to \pi_1(A, a)$ such that $\varphi \circ i_*$ is the identity on $\pi_1(A, a)$.



(b) Show that the inclusion induced map $\pi_1(A, a) \to \pi_1(X, a)$ is a monomorphism.

Exercise 47.9.



(a) Show that the two oriented 1-dimensional submanifolds A and B of $S^1 \times S^1$ that are shown in the figure on the left are not smoothly isotopic.

(b) We consider $\mathbb{R}^2$ with the two oriented 1-dimensional submanifolds X and Y that are shown in the figure on the right. Are these X and Y smoothly isotopic?

Remark. Beware of base points.

Exercise 47.10. Let X be a topological space, let $A \subset X$ be a path-connected subspace and let $x_0 \in A$. We denote by $i\colon A \to X$ the inclusion map. We suppose that the map $i_*\colon \pi_1(A, x_0) \to \pi_1(X, x_0)$ is an epimorphism. Finally let $\gamma\colon [0, 1] \to X$ be a path with $\gamma(0) \in A$ and $\gamma(1) \in A$. Show that there exists a homotopy $F\colon [0, 1] \times [0, 1] \to X$ rel $\{0, 1\}$ such that $F_0 = \gamma$ and such that F_1 takes values in A.

48. Fundamental groups and coverings

We have now introduced the fundamental group of a (pointed) topological space and we have proved several basic facts. But the only proof that fundamental groups are non-trivial relied on a fact from complex analysis. In particular, so far we have not yet managed to compute a single fundamental group that is not the trivial group. For example, we know that $\pi_1(S^1)$ is non-trivial, but we do not know what group it is.
In this chapter we will compute many non-trivial fundamental groups using the theory of covering spaces.

48.1. **Coverings of topological spaces.** Now we return to the study of topological spaces.

Definition. Let $p\colon X \to B$ be a map between topological spaces.

(1) We say an open subset $U \subset B$ is uniformly covered, if $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i\in I}$ with the property, that the restriction of p to each subset V_i is a homeomorphism.
(2) We say the map $p\colon X \to B$ is a[473] covering, if it is surjective and if for every $b \in B$ there exists an open neighborhood U of b which is uniformly covered.

Remark. If U is a uniformly covered subset of B, then clearly any open subset of U is also uniformly covered. For example it follows that if $p\colon X \to B$ is a covering and if B is locally (path-) connected, then any point $b \in B$ admits also a (*path*)- *connected* uniformly covered neighborhood.

Examples.

(a) The map

$$\begin{array}{rccc} p\colon \mathbb{R} & \to & S^1 \\ \varphi & \mapsto & \exp(\mathrm{i}\varphi) \end{array}$$

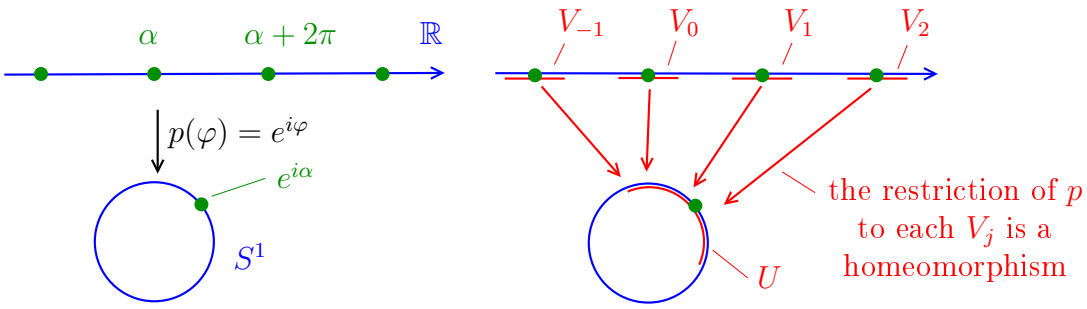
is a covering. Indeed, let $P = \exp(\mathrm{i}\alpha)$ be a point in S^1. We pick the open neighborhood

$$U := \left\{ \exp(\mathrm{i}\varphi) \,\middle|\, \varphi \in \left(\alpha - \tfrac{\pi}{4}, \alpha + \tfrac{\pi}{4}\right)\right\}.$$

Then

$$p^{-1}(U) := \bigsqcup_{j\in\mathbb{Z}} \underbrace{\left(\alpha - \tfrac{\pi}{4} + 2\pi j, \alpha + \tfrac{\pi}{4} + 2\pi j\right)}_{=:V_j},$$

and for each $j \in \mathbb{Z}$ the restriction of p to $V_j \to U$ is a homeomorphism. This example is illustrated in the figure below.

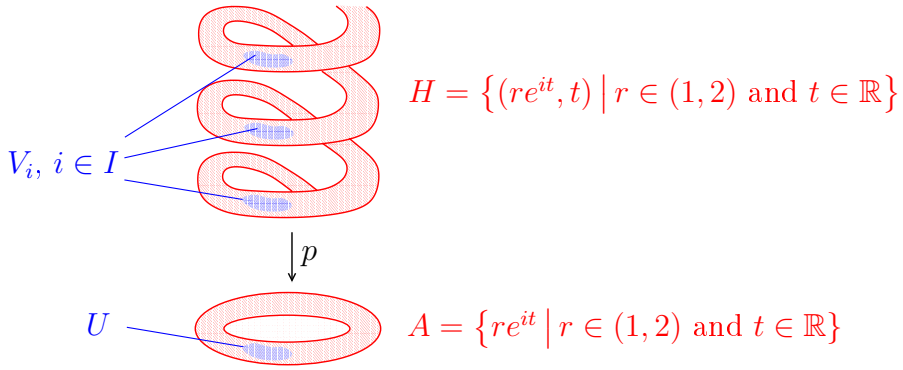


(b) We consider the "infinite helix"

$$H := \left\{ (r \cdot \exp(\mathrm{i}t), t) \,\middle|\, r \in (1,2) \text{ and } t \in \mathbb{R}\right\}$$

together with the "annulus"

$$A := \left\{ r \cdot \exp(\mathrm{i}t) \,\middle|\, r \in (1,2) \text{ and } t \in \mathbb{R}\right\}.$$



[473] On page 114 we introduced the notion of a "cover". As we mentioned on page 114, such a "cover" is sometimes also called a "covering". Now we introduce the notion of a "covering". Rather maddeningly, in the literature this notion often also gets called a "cover". Fortunately, from the context, it is usually clear what is meant by "cover" and "covering". These issues do not arise in other languages, e.g. in German and French what we call "cover" is referred to as "Überdeckung" and "recouvremement" and what we call "covering" is referred to as "Überlagerung" and "revêtement".

The map

$$\begin{array}{rcl} p\colon H & \to & A \\ (r\cdot\exp(\mathrm{i}t),t) & \mapsto & r\cdot\exp(\mathrm{i}t) \end{array}$$

is a covering. This statement is illustrated in the figure below. The proof of the statement is similar to the proof in the previous example.

(c) The map

$$\begin{array}{rcl} p\colon \mathbb{R}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ x & \mapsto & [x] = x+\mathbb{Z}^n \end{array}$$

is a covering. Indeed, let $[x] = [(x_1,\ldots,x_n)]$ be a point in $\mathbb{R}^n/\mathbb{Z}^n$. We consider

$$W \;:=\; \left\{(y_1,\ldots,y_n)\,\middle|\,|y_i - x_i| < \tfrac{1}{2}\right\} \subset \mathbb{R}^n$$

and we put $U := p(W)$. Then U is an open[474] neighborhood of $[x]$. Furthermore

$$p^{-1}(U) \;=\; \bigcup_{i\in\mathbb{Z}^n} (W+i),$$

and for each i the restriction of p to $W+i \subset \mathbb{R}^n$ is a homeomorphism.[475]

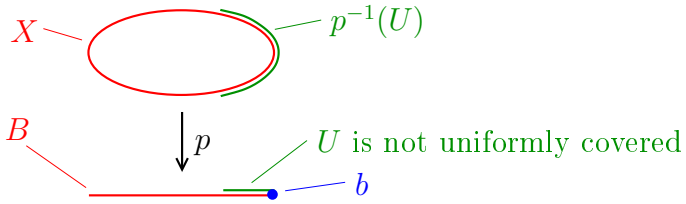
[474]The set U is open since the projection $p\colon \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ is open by the Group-Action Projection Lemma 5.24 (2a).

[475]It is straightforward to verify that the map $p\colon V_i := W+i \to U$ is a bijection. It follows from the Group-Action Projection Lemma 5.24 (1) that the projection p is continuous and as we had just mentioned in the previous footnote, the projection is also open. It follows that the map $p\colon V_i = W+i \to U$ is a homeomorphism.

(d) For every $n \in \mathbb{N}$ the map

$$\begin{array}{rcl} p\colon S^n & \to & \mathbb{R}\mathrm{P}^n = S^n/x \sim -x \\ x & \mapsto & [x] = \{x, -x\} \end{array}$$

is a covering. Indeed, for $[x] \in \mathbb{R}\mathrm{P}^n$ we set



$$W \;=\; \{y \in S^n \mid \underbrace{x \cdot y}_{\text{scalar product}} > 0\}.$$

Then $p(W)$ is an open neighborhood of $[x]$ and it is uniformly covered by the two open sets W and $-W$.

(e) The projection

$$\begin{array}{rcl} p\colon S^1 & \to & [-1,1] \\ (x,y) & \mapsto & x \end{array}$$

is *not* a covering. Indeed, the point $b = 1 \in [-1,1]$ has no open neighborhood that is uniformly covered. This example is illustrated in the figure below.

Lemma 48.1. Let $p\colon X \to B$ be a covering of topological spaces. If B is a path-connected topological space, then for any two points P and Q in B we have

$$\#p^{-1}(P) \;=\; \#p^{-1}(Q).$$

Proof. The proof of the lemma is the content of Exercise 48.1. ■

Example. For a general map $p\colon X \to B$ between topological spaces the number of preimages of a point depends of course on the point chosen in B. For instance in the above example (e) we have $\#p^{-1}(0) = 2$ but $\#p^{-1}(1) = 1$.

Definition. Let $p\colon X \to B$ be a covering of a path-connected non-empty topological space.

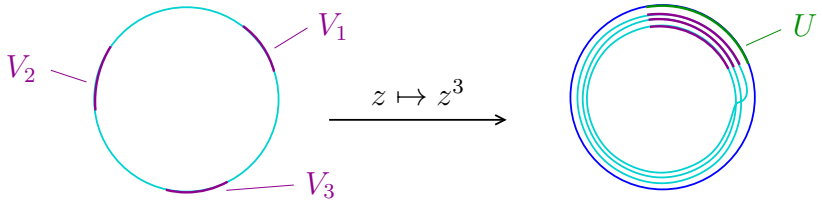
(1) We define the degree $[X : B]$ of p as the cardinality of $\#p^{-1}(b)$ for some $b \in B$.[476]
(2) If the degree is a finite number n, then we say that p is an n-fold covering of B. Otherwise we say that p is an infinite covering. If the cardinality is countable, then sometimes we call it a countable covering.

For completeness sake we extend this definition to the case that B, and thus also X, are the empty space. In this case we define the degree to be 1.

Examples.

(1) We had just seen that the map $p\colon S^n \to S^n/\sim$ is a 2-fold covering of the real projective space $S^n/\sim = \mathbb{R}\mathrm{P}^n$.

[476] It follows from Lemma 48.1 that this definition does not depend on the choice of b.



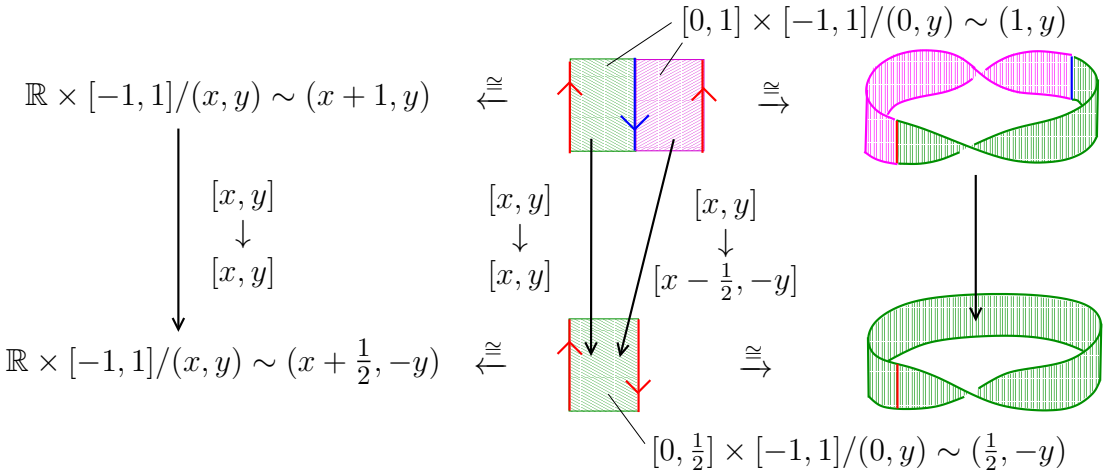
(2) Let $n \in \mathbb{N}$. As usual we consider $S^1 = \{z \in \mathbb{C} \,|\, |z| = 1\}$ as a subset of $\mathbb{C}$. Then the map $p\colon S^1 \to S^1$ given by $p(z) := z^n$ is a covering. Indeed, let $z = \exp(2\pi \mathrm{i}\varphi)$ be a point in S^1. Then

$$U \;:=\; \big\{ \exp(2\pi \mathrm{i}\psi) \,\big|\, \psi \in \big(\varphi - \tfrac{1}{4}, \varphi + \tfrac{1}{4}\big)\big\}$$

has the desired property. Indeed, we have

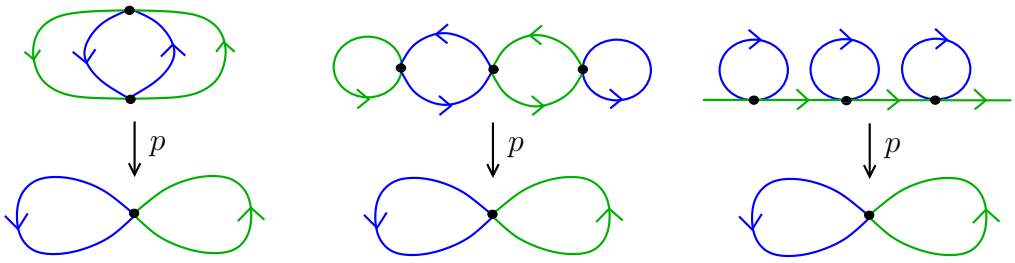
$$p^{-1}(U) \;=\; \bigsqcup_{j=1}^{n} \underbrace{\big\{ \exp(2\pi \mathrm{i}\psi) \,\big|\, \psi \in \big(\tfrac{1}{n}(\varphi - \tfrac{1}{4}) + \tfrac{j}{n}, \tfrac{1}{n}(\varphi + \tfrac{1}{4}) + \tfrac{j}{n}\big)\big\}}_{=:V_j},$$

and the restriction of p to each set V_j is easily seen to be a homeomorphism. This shows that p is a covering and it is clear that p is an n-fold covering.



(3) Let $n \in \mathbb{N}$. Note that basically the same argument as before shows that the map $p\colon \mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\}$ given by $p(z) = z^n$ is an n-fold covering.

(4) We consider the map



$$\begin{array}{rcl} p\colon \overbrace{\mathbb{R} \times [-1,1]/(x,y) \sim (x+1,y)}^{\text{annulus}} & \to & \overbrace{\mathbb{R} \times [-1,1]/(x,y) \sim (x+\frac{1}{2},-y)}^{\text{Möbius band}} \\ [(x,y)] & \mapsto & [(x,y)]. \end{array}$$

It is straightforward to show that p is a 2-fold covering. Thus we can view the annulus as a 2-fold covering of the Möbius band. This covering is illustrated in the figure below.

(5) If in the previous example we replace the interval $[-1,1]$ by the circle $[-1,1]/-1 \sim 1$, then on the left-hand side we obtain the torus and on the right-hand side we obtain the Klein bottle. This shows that there exists a degree 2 covering map from the torus to the Klein bottle.

(6) In the figure below we sketch three coverings of topological graphs. The coverings are hereby given by sending edges of a certain color, with the indicated direction, to the edge of the same color with the indicated direction.[477]

2-fold covering 3-fold covering infinite covering

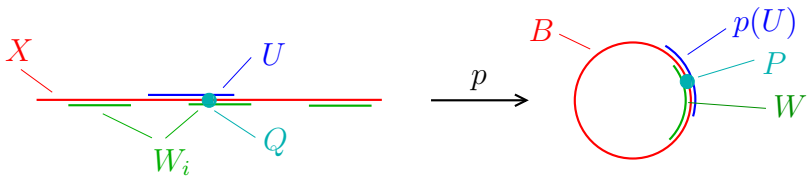
Question 48.2. We had just seen that there exists a covering map $S^2 \to \mathbb{R}\mathrm{P}^2$ of degree two and that there exists a covering map from the torus to the Klein bottle of degree two. This raises the question: between which surfaces do there exist covering maps? More precisely we can ask the following:

(1) Does there exist a covering map from the torus $S^1 \times S^1$ to the sphere S^2?
(2) Does there exist a covering map from the sphere S^2 to the torus $S^1 \times S^1$?

The following lemma summarizes some basic facts about coverings.

Lemma 48.3. Let $p\colon X \to B$ be a covering of topological spaces. Then the following hold:

(1) The map $p\colon X \to B$ is open.[478]
(2) For any $b \in B$ the preimage $p^{-1}(b)$ is a discrete subset of X.
(3) If B is Hausdorff, then X is also Hausdorff.
(4) If p is a finite covering and if B is compact, then X is also compact.
(5) If p is an infinite covering, then X is non-compact.



Proof. Let $p\colon X \to B$ be a covering of topological spaces.

(1) Let U be an open subset of X. We need to show that $p(U)$ is open. It suffices to show that for each $P \in p(U)$ there exists an open neighborhood V such that $P \in V \subset U$. Since p is a covering there exists an open neighborhood W of P such that $p^{-1}(W)$ is the union of disjoint open subsets $\{W_i\}_{i\in I}$ with the property that the restriction of p to each subset W_i is a homeomorphism.

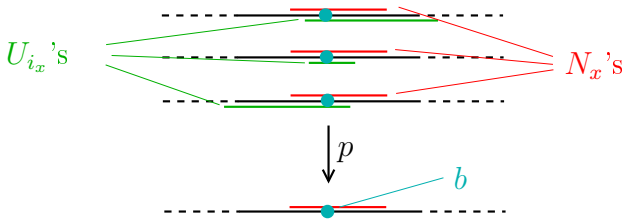
Since $P \in p(U)$ there exists a $Q \in U$ with $p(Q) = U$. There exists an $i \in I$ with $Q \in W_i$. Since W_i is open and since U is open the set $U \cap W_i$ is also open in X. Since $p\colon W_i \to W$ is a homeomorphism and since $U \cap W_i$ is open in W_i the set $p(U \cap W_i)$ is also open in $p(W_i) = W$. But since W is open the set $V := p(U \cap W_i)$ is also an open subset of B. It is the desired open neighborhood of P with $P \in V \subset U$.

(2) Let $b \in B$. Since $p\colon X \to B$ is a covering there exists an open neighborhood U of b such that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i\in I}$ with the property that the restriction of p to each subset V_i is a homeomorphism. For each $i \in I$ there

[477] It is a good exercise to convince oneself, that the indicated maps are in fact coverings.
[478] Recall that this means that the image of each open set in X is open in B.

exists a unique point $x_i \in V_i$ with $p(x_i) = b$ and the preimage $p^{-1}(b)$ consists of precisely the x_i, $i \in I$. Since each V_i is open in X it follows from the definition of the subspace topology that each $x_i \in p^{-1}(b)$ is an open subset of $p^{-1}(b)$. Put differently, the subspace topology on $p^{-1}(b)$ is the discrete topology. But this is equivalent to saying that $p^{-1}(b)$ is a discrete subset of X.

(3) This statement is relatively easy to prove.We will provide the details in Exercise 48.4.



(4) Let $p\colon X \to B$ be an n-fold covering of a compact space B. Let $\{U_i\}_{i\in I}$ be an open cover of X. Let $b \in B$. We pick an open connected neighborhood M of b that is uniformly covered. For each $x \in p^{-1}(b)$ we denote by N_x the component of $p^{-1}(M)$ that contains x. For each point in $x \in p^{-1}(b)$ we pick an $i_x \in I$ with $x \in U_{i_x}$. We write

$$W_b := \bigcap_{x\in p^{-1}(b)} p(U_{i_x} \cap N_x).$$

Claim. The preimage $p^{-1}(W_b)$ is contained in the union of $n = \#p^{-1}(b)$ subsets of our open cover $\{U_i\}_{i\in I}$.

Proof. Since M is uniformly covered the map $p\colon N_x \to M$ is a homeomorphism for any $x \in p^{-1}(y)$. We denote by $p_x\colon N_x \to M$ this homeomorphism. We write $F := p^{-1}(b)$. We then have

$$p^{-1}(W_b) = \bigcup_{y\in F} p_y^{-1}\Big(\bigcap_{x\in F} p_x(U_{i_x} \cap N_x)\Big) = \bigcup_{y\in F}\overbrace{\bigcap_{x\in F} \underbrace{p_y^{-1}(p_x(U_{i_x}))}_{=U_{iy} \text{ if } y=x} \cap \underbrace{p_y^{-1}(p_x(N_x))}_{=N_y}}^{\subset U_{iy}\cap N_y} \subset \bigcup_{y\in F} U_{iy}.$$ ⊞

By (1) each $p(U_{i_x} \cap N_x)$ is an open subset of B and since $p^{-1}(b)$ is a finite set we see that W_b is an open subset of B. Furthermore b is contained in each $p(U_{i_x} \cap N_x)$, so W_b is in fact an open neighborhood of $b \in B$. Since B is compact we can cover B by finitely many of these open sets, i.e. there exist $b_1, \ldots, b_k \in B$ with $B = W_{b_1} \cup \cdots \cup W_{b_k}$. The preimages $p^{-1}(W_{b_1}), \ldots, p^{-1}(W_{b_k})$ cover X. By the above claim each preimage $p^{-1}(W_{b_i})$ is contained in the union of $n = \#p^{-1}(b_i)$ subsets of our open cover $\{U_i\}_{i\in I}$. Summarizing we have shown that we can cover X by $n \cdot k$ sets out of the collection $\{U_i\}_{i\in I}$.

(5) Let $p\colon X \to B$ be an infinite covering. If B is non-compact, then it follows from the Compact Image Lemma 2.13 that X is also non-compact. So now suppose that B is compact. By definition we can cover B by open sets that are uniformly covered.

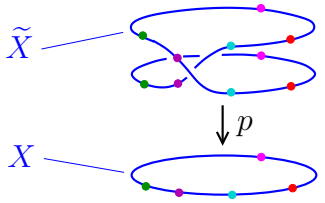
Since B is compact we can cover B by finitely many open sets $U_1, \ldots, U_k$ that are uniformly covered. Without loss of generality we can assume that U_k is not contained in $U_1 \cup \cdots \cup U_{k-1}$.[479] Now let P be a point in $U_k \setminus (U_1 \cup \cdots \cup U_{k-1})$. Furthermore let V_i, $i \in I$ be the disjoint open subsets of X such that $p^{-1}(U_k)$ is the union of the V_i's and such that the restriction of p to each V_i is a homeomorphism. For $i \in I$ we denote by $Q_i \in V_i$ the unique point with $p(Q_i) = P$. Now we consider the open cover

$$X \;=\; p^{-1}(U_1) \cup \ldots \cup p^{-1}(U_{k-1}) \cup \bigcup_{i \in I} V_i.$$

Note that for $i \in I$ the point Q_i is contained only in V_i. This means that we cannot remove any of the open sets V_i, $i \in I$ from the open cover. Since I is infinite it follows that X does not satisfy the definition of a compact set, i.e. X is not compact. ■

We conclude this section with the following lemma.

Lemma 48.4. Let $p\colon \widetilde{X} \to X$ be a 2-fold covering of a topological space X.



(1) The map

$$\begin{array}{rccl} \Xi\colon & \widetilde{X} & \to & \widetilde{X} \\ & x & \mapsto & \text{the unique element in } p^{-1}(p(\{x\})) \setminus \{x\} \end{array}$$

is continuous.

(2) Let A be a topological space and let $f\colon A \to X$ be a map. We say a map $\widetilde{f}\colon A \to \widetilde{X}$ is a *lift of* f, if $p \circ \widetilde{f} = f$. If $\widetilde{f}\colon A \to \widetilde{X}$ is a lift of f, then $\Xi \circ \widetilde{f}$ is the unique other lift of f.

Proof. We will prove the lemma in Exercise 48.21. ■

$\Xi\colon \widetilde{X} \to \widetilde{X}$ swaps the points of the same color

48.2. **Group actions and covering spaces.** We recall two definitions about actions from pages 248 and 253 and we introduce one new definition.

Definition. Let G be a group which acts continuously on a topological space X.

(1) We say G acts freely if $g \cdot x = x$ for $g \in G$ and $x \in X$ implies that $g = e$.

(2) We say G acts properly if for every two points x and y in X there exist open neighborhoods U of x and V of y such that the set $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is finite.

(3) We say G acts discretely, if for each $x \in X$ there exists an open neighborhood U so that

$$U \cap g \cdot U \;=\; \varnothing \quad \text{for all } g \neq e.$$

The following lemma summarizes the relationship between these different definitions.

Lemma 48.5. Let G be a group which acts continuously on a topological space X.

(1) If G is finite, then the action is proper.

[479] Indeed, if U_k was contained in $U_1 \cup \cdots \cup U_{k-1}$, then we could remove U_k from the collection of open sets and we continue with the collection $U_1, \ldots, U_{k-1}$.

(2) If G acts discretely, then it also acts freely.
(3) If X is a Hausdorff space and if the action by G is free and proper, then the action is also discrete.

Proof. The first two statements follow immediately from the definitions. The third statement is the content of Lemma 19.35. ■

Examples.

(A) The group $G = \mathbb{Z}^n$ acts on $X = \mathbb{R}^n$ by addition. This action is discrete. Indeed, for each $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ the open neighborhood

$$U \;=\; \left\{ y = (y_1, \ldots, y_n) \in \mathbb{R}^n \;\middle|\; \max\{|x_1 - y_1|, \ldots, |x_n - y_n|\} < \tfrac{1}{2} \right\}$$

has the desired property.

(B) Let $X = \mathbb{R} \times [-1, 1]$ and $G = \mathbb{Z}$. The action

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n, (x, y)) & \mapsto & (x + n, (-1)^n y) \end{array}$$

is discrete. Indeed, for any $(x, y) \in X$ the open neighborhood

$$U \;=\; \left\{ (a, b) \;\middle|\; |a - x| < \tfrac{1}{2} \text{ and } b \in [-1, 1] \right\}$$

has the desired property.

(C) Let $X = S^n$ and $G = \{\pm 1\}$. The map

$$\begin{array}{rcl} \{\pm 1\} \times S^n & \to & S^n \\ (\epsilon, P) & \mapsto & \epsilon \cdot P \end{array}$$

defines an action that is discrete. Indeed, for any $P \in S^n$ the open hemisphere

$$U \;=\; \{ Q \in S^n \mid \underbrace{P \cdot Q}_{\text{scalar product}} > 0 \}$$

has the desired property.[480]

(D) Every discrete action is free, but as we will see in this example, the converse does not hold. Let $X = \mathbb{R}^{n+1} \setminus \{0\}$ and $G = \mathbb{R} \setminus \{0\}$. The map

$$\begin{array}{rcl} (\mathbb{R} \setminus \{0\}) \times (\mathbb{R}^{n+1} \setminus \{0\}) & \to & \mathbb{R}^{n+1} \setminus \{0\} \\ (r, P) & \mapsto & r \cdot P \end{array}$$

defines an action. It is straightforward to see that the action is free. But the action is not discrete. Indeed, it is easy to see that for each open non-empty set U there exist uncountably many real numbers $r \neq 1$ with $U \cap rU \neq \varnothing$.

(E) As in Exercise 25.11 we consider the following two self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x, y) & \mapsto & (x + 1, 1 - y) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x, y) & \mapsto & (x, y + 1). \end{array}$$

[480] Alternatively one can argue, that the action is obviously free and S^n is Hausdorff, hence the action is discrete by Lemma 48.5 (1) and (3).

We denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means

$$G = \begin{array}{c}\text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}.\end{array}$$

The group G acts by definition on $\mathbb{R}^2$. In Exercise 48.8 we will see that this action of G on $\mathbb{R}^2$ is discrete. Note that in Exercise 25.11 we already saw that the obvious map $[0,1] \times [0,1]/\sim \to \mathbb{R}^2/G$ defines a homeomorphism from the Klein bottle, as defined on page 265, to the quotient space $\mathbb{R}^2/G$.

(F) Let

$$X = S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\}$$

and let $G = \mathbb{Z}_p$ for some $p \in \mathbb{Z} \setminus \{0\}$. Furthermore let $q \in \mathbb{Z}$ with $\gcd(p,q) = 1$. Then the map

$$\begin{array}{rcl} \mathbb{Z}_p \times S^3 & \to & S^3 \\ (k + p\mathbb{Z}, (z_1, z_2)) & \mapsto & (\exp(2\pi \mathrm{i} k/p) \cdot z_1, \exp(2\pi \mathrm{i} kq/p) \cdot z_2) \end{array}$$

defines a smooth, orientation-preserving and discrete action of $\mathbb{Z}_p$ on S^3.[481] We denote by $L(p,q) = S^3/\mathbb{Z}_p$ the quotient space. It follows from the Manifold Quotient-by-Group Action Proposition 19.32 that $L(p,q)$ is again a closed 3-dimensional smooth manifold. Furthermore it follows from the Orientation-Action Proposition 25.19 that $L(p,q)$ is orientable, in fact it has an orientation such that the projection $p\colon S^3 \to L(p,q)$ is orientation-preserving. We will always view $L(p,q)$ as a smooth manifold equipped with this orientation. We refer to the smooth manifolds $L(p,q)$ as *lens spaces*.[482] We consider two special cases:

(a) For $p = 1$ we only have the action of the trivial group on S^3 and the quotient space $L(1,q)$ is therefore just the original sphere S^3.

(b) For $p = 2$ we have q is odd, so for $k = 0$ we have $\exp(2\pi \mathrm{i} k/2) = \exp(2\pi \mathrm{i} kq/2) = 1$ and for $k = 1$ we have $\exp(2\pi \mathrm{i} k/2) = \exp(2\pi \mathrm{i} kq/2) = -1$. Put differently, the action of $\mathbb{Z}_2$ on S^3 is the same as the action of $\mathbb{Z}_2 = \{\pm 1\}$ that we had used in the definition of the real projective space $\mathbb{R}\mathrm{P}^3$. This shows that $L(2,q) = \mathbb{R}\mathrm{P}^3$.

We discuss the last type of examples in slightly more detail. For $p \in \mathbb{N}$ and $q \in \mathbb{N}$ with $\gcd(p,q) = 1$ we just introduced a new topological space, namely the lens space $L(p,q)$. It is natural to ask, for which parameters (p,q) are these topological spaces homeomorphic?

Lemma 48.6. (Lens Spaces-Diffeomorphisms Lemma) Let $p \in \mathbb{N}$ and furthermore let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. If $q \equiv \pm r^{\pm 1} \bmod p$,[483] then $L(p,q)$ and $L(p,r)$ are diffeomorphic.[484]

---

[481] It is straightforward to verify that the map does indeed define an action. It is clear that the action is smooth and a direct calculation shows that the action is orientation-preserving. One can also easily verify that the action is free. It follows from Lemma 48.5 (1) and (3) that the action is discrete.

[482] The name "lens space" comes from an alternative description of these smooth manifolds.

[483] By our hypothesis we have $\gcd(p,r) = 1$. This implies that there exists a multiplicative inverse of r modulo p, i.e. there exists an s with $r \cdot s \bmod p$. We write $r^{-1} := s$.

[484] In particular any lens space is of the form $L(p,q)$ with $q \in \{0, \ldots, p-1\}$.

Proof. Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. We suppose that $q \equiv \pm r^{\pm 1} \bmod p$. We define a map

as follows:

$$\begin{array}{lrcl} & L(p,q) & \to & L(p,r) \\ \text{Case 1: } q \equiv r \bmod p. & [(z_1,z_2)] & \mapsto & [(z_1,z_2)] \\ \text{Case 2: } q \equiv -r \bmod p. & [(z_1,z_2)] & \mapsto & [(z_1,\overline{z_2})] \\ \text{Case 3: } q \equiv r^{-1} \bmod p. & [(z_1,z_2)] & \mapsto & [(z_2,z_1)] \\ \text{Case 4: } q \equiv -r^{-1} \bmod p. & [(z_1,z_2)] & \mapsto & [(z_2,\overline{z_1})] \end{array}$$

In all four cases it is straightforward to verify that the given map is well-defined and that it is in fact a diffeomorphism. ■

In the proof of the Lens Spaces-Diffeomorphisms Lemma 48.6 it was quite straightforward to write down the homeomorphism. This raises the question whether there are homeomorphisms between more lens spaces that are harder to find, or whether all other pairs of lens spaces are non-homeomorphic. More precisely, we have the following question.

Question 48.7. Let $p, \widetilde{p} \in \mathbb{N}$ and let $q, \widetilde{q} \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(\widetilde{p},\widetilde{q}) = 1$. If $L(p,q)$ and $L(\widetilde{p},\widetilde{q})$ are homeomorphic, does it follow that $p = \widetilde{p}$ and $q \equiv \pm\widetilde{q}^{\pm 1} \bmod p$?

This question will keep us busy for a very long time. We will eventually provide the answer in the Lens Space-Homeomorphism Classification Theorem **??**.

We had just seen on page 1074 that the group $\{\pm 1\}$ acts freely and continuously on any sphere. We had also seen that any finite cyclic group $\mathbb{Z}_p$ acts freely and continuously on the 3-sphere. This raises the question, whether such an action by $\mathbb{Z}_p$ also exists on the 2-sphere. More generally we can ask the following question.

Question 48.8. Given $n \in \mathbb{N}$, which finite cyclic groups can act freely and continuously on the n-dimensional sphere S^n?[485]

We will give a complete answer to this question once we have introduced homology groups, see Exercise 76.21 and Proposition 87.10.

The following proposition connects the notion of discrete actions to the theory of covering spaces.

Proposition 48.9. (Actions-Covering Proposition) Let X be a topological space together with a discrete and continuous action by a group G. Then the natural projection $p\colon X \to X/G$ is a covering.

Example. This proposition, combined with examples (A) and (C), gives in particular new proofs that the maps $\mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ and $S^n \to S^n/\!\sim = \mathbb{R}\mathrm{P}^n$ are covering maps.

Proof. Let G be a group which acts discretely and continuously on a topological space X. We want to show that the projection $p\colon X \to X/G$ is a covering. Let $[x] \in X/G$. Since the group acts discretely there exists an open neighborhood V of $x \in X$ such that

$$V \cap gV \;=\; \varnothing \text{ for all } g \neq e.$$

[485] Any cyclic group $\mathbb{Z}_k$, $k \neq 0$ admits a non-trivial action on S^n where $j \in \mathbb{Z}_k$ acts by rotation around the x-axis by the angle $2\pi\frac{j}{k}$. But this action is not free, since the points $(-1,0,\ldots,0)$ and $(1,0,\ldots,0)$ are fixed.

We put $U := p(V)$. It follows from the Group-Action Projection Lemma 5.24 that the set U is an open neighborhood of $[x] = p(x)$. The preimage $p^{-1}(U)$ is the disjoint union of the open subsets[486] $gV, g \in G$. The restriction of the map p to any gV is a continuous, bijective[487] map $gV \to U$ and according to Lemma 5.24 this map is furthermore open. It follows that the restriction of p to any gV is in fact a homeomorphism. Thus we see that U is uniformly covered. Since this holds for any point in X/G we have shown that the projection $p\colon X \to X/G$ is a covering. ■

The following proposition is a slight generalization of the previous proposition.

Proposition 48.10. Let X be a topological space together with a discrete and continuous action by a group G. Furthermore let H be a subgroup of G. Then the natural projection

$$\begin{array}{rcl} p\colon X/H & \to & X/G \\ [x] & \mapsto & [x] \end{array}$$

is a covering.

For H the trivial group we recover the statement of the Actions-Covering Proposition 48.9. In fact the proof of Proposition 48.10 is almost identical to the proof of the Actions-Covering Proposition 48.9. We leave the details to the reader.

Examples.

(1) Let $X = \mathbb{R} \times [-1,1]$ and $G = \mathbb{Z}$. Once again we consider the discrete action

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n,(x,y)) & \mapsto & \big(x + \frac{1}{2}n, (-1)^n y\big). \end{array}$$

Let $H = 2\mathbb{Z}$. According to Proposition 48.10 the projection $p\colon X/H \to X/G$ is a covering. Put differently, all the horizontal maps in the following commutative diagram are coverings:

$$\begin{array}{ccc} (\mathbb{R}\times[-1,1])/2\mathbb{Z} & \longrightarrow & (\mathbb{R}\times[-1,1])/\mathbb{Z} \\ \downarrow \text{id} & & \downarrow \text{id} \\ (\mathbb{R}\times[-1,1])/(x,y) \sim (x+\frac{1}{2}2k,(-1)^{2k}y) & \longrightarrow & (\mathbb{R}\times[-1,1])/(x,y) \sim (x+\frac{1}{2}k,(-1)^k y) \\ \downarrow \text{id} & & \downarrow \text{id} \\ \underbrace{(\mathbb{R}\times[-1,1])/(x,y) \sim (x+k,y)}_{=\text{the annulus}} & \longrightarrow & \underbrace{(\mathbb{R}\times[-1,1])/(x,y) \sim (x+\frac{1}{2}k,(-1)^k y).}_{=\text{Möbius band}} \end{array}$$

Each point on X/G has precisely two preimages, so the covering is in fact a 2-fold covering. Thus we recover the result from page 1070 that the annulus is a 2-fold covering of the Möbius band.

(2) We consider again the group G of self-homeomorphisms of $\mathbb{R}^2$ that is generated by

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1). \end{array}$$

[486] Why is $p^{-1}(U) = \bigcup_{g\in G} gV$ and why are the sets gV disjoint?

[487] Why is the map bijective?

We let H be the subgroup of G generated by A^2 and B. Note that A^2 is the map given by

$$\begin{array}{rcccc} A^2\colon \mathbb{R}^2 & \xrightarrow{A} & \mathbb{R}^2 & \xrightarrow{A} & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1,1-y) & \mapsto & \underbrace{((x+1)+1,(1-(1-y))}_{=(x+2,y)}. \end{array}$$

Note that A^2 and B are two homeomorphisms that commute, so any element in H is in fact of the form

$$\begin{array}{rcl} A^{2k}\circ B^l\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+2k, y+l) \end{array}$$

for some $k,l\in\mathbb{Z}$. By Proposition 48.10 the projection $p\colon \mathbb{R}^2/H \to \mathbb{R}^2/G$ is a covering map. We already know that $\mathbb{R}^2/G$ is the Klein bottle. It follows immediately from the above description of H, $\mathbb{R}^2/H = \mathbb{R}^2/(2\mathbb{Z}\oplus\mathbb{Z})$, so $\mathbb{R}^2/H$ is just the 2-dimensional torus. As on page 1070 we see that we can view the 2-dimensional torus as a 2-fold covering of the Klein bottle.

48.3. Lifting of paths.

Definition. Let $p\colon X\to B$ be a map between topological spaces and let $f\colon [a,b]\to B$ be a path. Let $x\in X$ be a point with $p(x)=f(a)$. A path $g\colon [a,b]\to X$ is called a lift of f to the starting point x, if $g(a)=x$ and if $p\circ g = f$, i.e. if the following diagram of maps commutes:

$$\begin{array}{ccc} & & X \\ & \overset{g}{\nearrow} & \big\downarrow p \\ [a,b] & \xrightarrow[f]{} & B. \end{array}$$

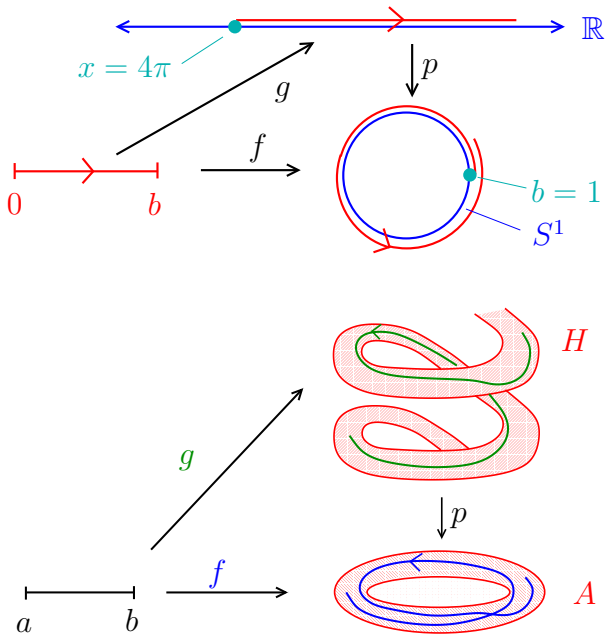
Examples.

(1) We consider the map

$$\begin{array}{rcl} p\colon \mathbb{R} & \to & S^1 \\ t & \mapsto & \exp(\mathrm{i}t) \end{array}$$

and the path

$$\begin{array}{rcl} f\colon [0,b] & \to & S^1 \\ t & \mapsto & \exp(2\mathrm{i}t) \end{array}$$



with starting point $f(0)=1$. Let $x=4\pi$. Then $p(x)=p(4\pi)=1$ and

$$\begin{array}{rcl} g\colon [0,b] & \to & \mathbb{R} \\ t & \mapsto & 4\pi+2t \end{array}$$

is a lift of f to the starting point 4π. Note that if $b=\pi$, then f is a loop in $(S^1,1)$, but the lift is not a loop in $(\mathbb{R},4\pi)$. Put differently, the lift of a loop is not necessarily again a loop. This example is illustrated in the figure below.

(2) In the figure below we illustrate the lifting of a path in the covering $p\colon H\to A$ of an infinite helix over an annulus that we had considered on page 1068.

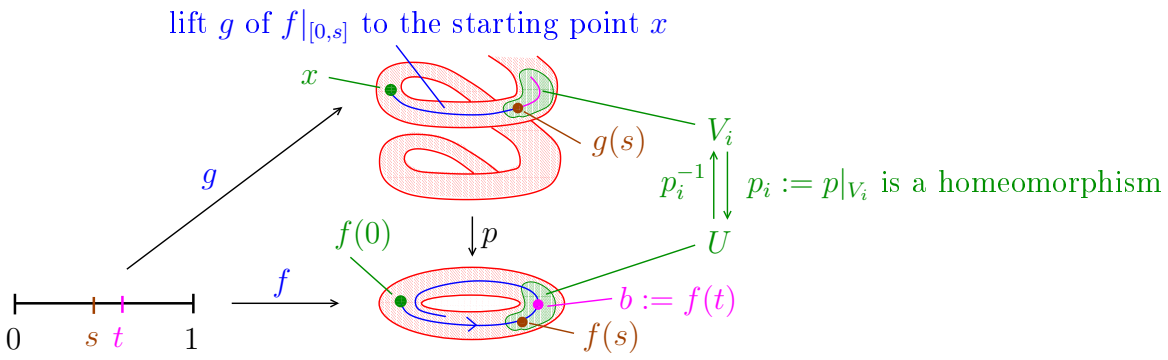
Proposition 48.11. Let $p\colon X\to B$ be a covering and let $f\colon [0,1]\to B$ be a path. Then given any $x\in X$ with $p(x)=f(0)$ there exists a unique lift $g\colon [0,1]\to X$ of f to the starting point x.

Proof. Let $p\colon X \to B$ be a covering, let $f\colon [0,1] \to B$ be a path and let x be a point in X with $p(x) = f(0)$. We first show the existence of a lift and then we prove the uniqueness of the lift.

(a) We consider

$$S \;:=\; \big\{ s \in [0,1] \,\big|\, \text{there exists a lift of } f|_{[0,s]} \text{ to the starting point } x \big\}.$$

Note that S is non-empty since 0 has the desired property. We put $t := \sup(S)$. We want to show that $t = 1$ and that $t \in S$. It suffices to show that there exists an $\epsilon > 0$ such that $[t, t+\epsilon) \cap [0,1]$ still lies in S. We set $b := f(t)$. Since p is a covering there exists an open neighborhood U of $b \in B$, which is uniformly covered. As a reminder, this means that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i \in I}$ with the property that the restriction of p to each subset V_i is a homeomorphism. Since U is open and since f is continuous there exists an $\epsilon > 0$ such that $f((t-\epsilon, t+\epsilon) \cap [0,1]) \subset U$.



By the definition of t there exists an $s \in (t-\epsilon, t] \cap S$. We denote by g the lift of $f|_{[0,s]}$ the starting point x. There exists a unique $i \in I$ such that $g(s) \in V_i$. We denote by $p_i\colon V_i \to U$ the homeomorphism which is given by the restriction of p to V_i.

We consider the map

$$\begin{array}{rcl} h\colon [0, t+\epsilon) \cap [0,1] & \to & X \\ z & \mapsto & \begin{cases} g(z), & \text{if } z \in [0,s], \\ p_i^{-1}(f(z)), & \text{if } z \in (s, t+\epsilon) \cap [0,1]. \end{cases} \end{array}$$

Since $g(s) = p_i^{-1}(f(s))$ we see that this map is indeed continuous. It is clear that this defines a lift of f to the starting point x.

(b) Now we show the uniqueness of the lift. The proof of that statement is similar to the proof of the existence of a lift. So suppose that $g, h\colon [0,1] \to X$ are two lifts of f to

the starting point x. We want to show that $g = h$. We consider

$$S \;:=\; \{s \in [0,1] \,|\, g(t) = h(t) \text{ for all } t \in [0,s]\}\,.$$

Note that $0 \in S$, i.e. S is non-empty. We put $t := \sup(S)$. We want to show that $t = 1$ and that $t \in S$. Again it suffices to show that there exists an $\epsilon > 0$ such that $[t, t+\epsilon) \cap [0,1]$ still lies in S.

We put $b := f(t)$. Since p is a covering there exists an open neighborhood U of $b \in B$ which is uniformly covered. Since U is open and since f is continuous there exists an $\epsilon > 0$ such that $f((t-\epsilon, t+\epsilon) \cap [0,1]) \subset U$. We pick an $s \in (t-\epsilon, t] \cap [0,1]$. There exists a unique $i \in I$ such that $g(s) \in V_i$. We denote by $p_i \colon V_i \to U$ the homeomorphism which is given by the restriction of p to V_i.

Since $g(s) = h(s)$ it follows that $h(s) \in V_i$. Then it follows that $g(z) \in V_i$ and $h(z) \in V_i$ for all $z \in (t-\epsilon, t+\epsilon) \cap [0,1]$. It follows from the definitions that

$$g(z) \;=\; p_i^{-1}(f(z)) \quad \text{and} \quad h(z) \;=\; p_i^{-1}(f(z))$$

for all $z \in (t-\epsilon, t+\epsilon) \cap [0,1]$. In particular $[t, t+\epsilon) \cap [0,1]$ lies in S. ∎

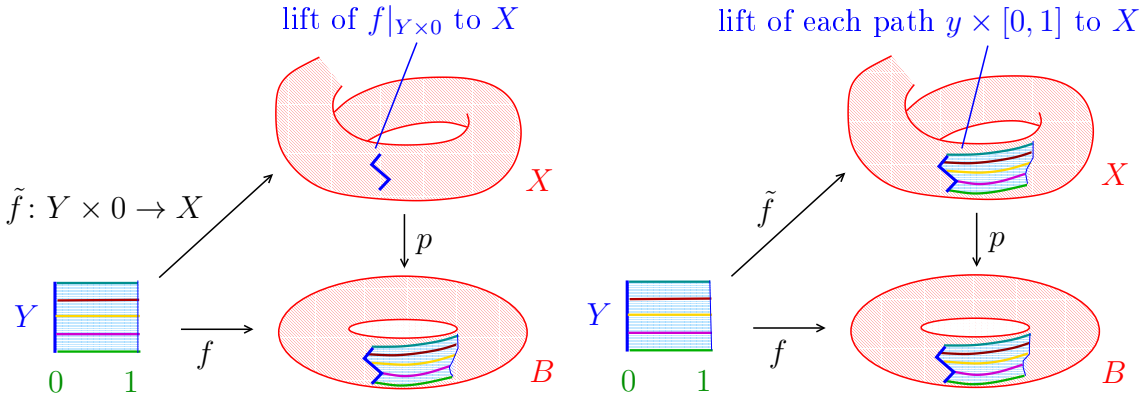
48.4. **Lifting of path-homotopies.** In the last chapter we saw that given a covering map $p \colon X \to B$ any path $f \colon [0,1] \to B$ can be lifted to a path $g \colon [0,1] \to X$. In this chapter we want to study the question whether the lifts of path-homotopic paths are still path-homotopic.

Before we start this discussion we first generalize the notion of a lift.

Definition. Let $p \colon X \to B$ be a covering and let $f \colon Y \to B$ be a map between topological spaces. A lift of f to X is a map[488] $\widetilde{f} \colon Y \to X$ such that $p \circ \widetilde{f} = f$, i.e. such that the following diagram of maps commutes:

$$\begin{array}{ccc} & & X \\ & \overset{\widetilde{f}}{\nearrow} & \big\downarrow p \\ Y & \xrightarrow[f]{} & B. \end{array}$$

Proposition 48.12. (Path-Homotopy Lifting Proposition) Let $p \colon X \to B$ be a covering, let B be a topological space, let Y be a topological manifold[489] and let $f \colon Y \times$



[488] Once again, all maps are understood to be continuous.

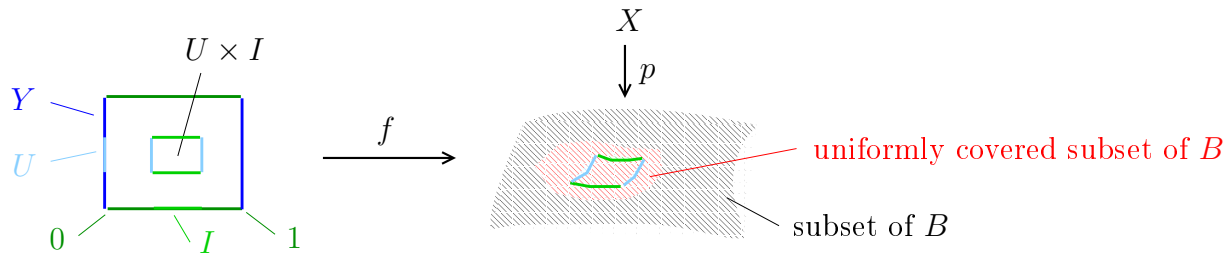
$[0,1] \to B$ be a map. Furthermore let $\widetilde{f}\colon Y \times 0 \to X$ be a lift of $f|_{Y\times 0}$. Let

$$\widetilde{f}\colon Y \times [0,1] \ \to \ X$$

be the map that is uniquely determined[490] by the property that for each $y \in Y$ the path $t \mapsto \widetilde{f}(y,t)$ is the lift of the path $t \mapsto f(y,t)$ to the starting point $\widetilde{f}(y,0)$. Then the map $\widetilde{f}\colon Y \times [0,1] \to X$ is continuous.

One way of formulating the Path-Homotopy Lifting Proposition 48.12 is that a "continuous" family of paths in B lifts again to a "continuous" family of paths in X.

Proof. Let $p\colon X \to B$ be a covering, let $f\colon Y \times [0,1] \to B$ be a continuous map and let $\widetilde{f}\colon Y \times 0 \to X$ be a continuous lift of $f|_{Y\times 0}$. (Here and throughout this proof we do not suppose that all maps are continuous.) We begin with the following definitions:



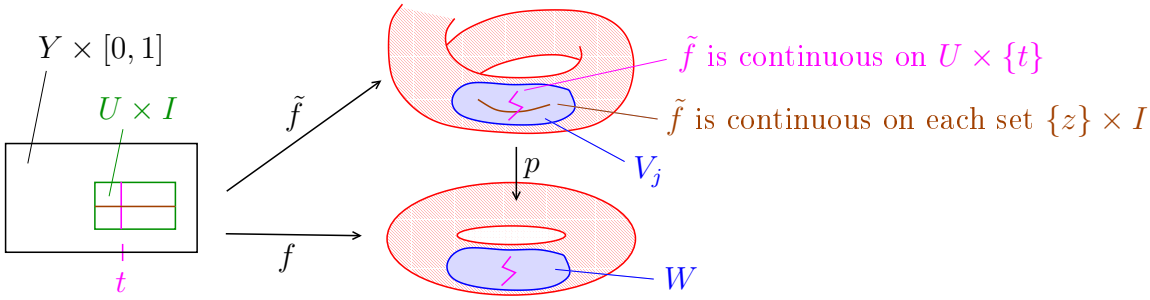
(1) A *good set* $U \times I$ consists of a connected subset $U \subset Y$ and an open interval[491] $I \subset [0,1]$ such that $f(U \times I)$ lies in a uniformly covered subset of B.
(2) We say a good set $U \times I$ is *very good*, if there exists a $t \in I$ such that the restriction of $\widetilde{f}$ to $U \times \{t\}$ is continuous.
(3) Let $y \in Y$ and $t \in [0,1]$. A (*very*) *good neighborhood of* (y,t) is a (very) good set $U \times I$ with $y \in U$ and $t \in I$.

It follows easily[492] from the continuity of f, the hypothesis that Y is a topological manifold and the fact that $p\colon X \to B$ is a covering that each point (y,t) admits a good neighborhood.[493]

Claim. Let $U \subset Y$ open and let $I \subset [0,1]$ be an open interval such that $U \times I$ is very good. Then $\widetilde{f}$ is continuous on $U \times I$.

---

[489] Later on we will apply the proposition to the case that $Y = [0,1]$ and that $Y = \overline{B}^n$ for some $n \in \mathbb{N}_0$.
[490] The existence and the uniqueness of this map is an immediate consequence of Proposition 48.11.
[491] We say $A \subset [0,1]$ is an open interval, if A is an interval and if A is open with respect to the subspace topology of $[0,1]$. Put differently, $A = (a,b)$, or $A = [0,a)$ or $A = (b,1]$ or $A = [0,1]$ for $0 \le a \le b \le 1$.
[492] Why does this follow?
[493] Here we use the fact, established in the Path-Connected Implies Connected Corollary 2.23 and the Topological Manifolds-Local Properties Lemma 18.8 (2), that the topological manifold Y is locally connected.



Proof. Let $U \subset Y$ be an open connected subset and let $I \subset [0,1]$ be an interval such that $U \times I$ is very good. This means in particular that there exists a $t \in I$ such that

$$\begin{array}{ccc} U & \to & X \\ y & \mapsto & \widetilde{f}(y,t) \end{array}$$

is continuous.

According to our hypothesis there exists a uniformly covered subset $W \subset B$ such that $f(U \times I) \subset W$. Since $U \times I$ is connected we can without loss of generality suppose that W is connected. Since W is uniformly covered the preimage $p^{-1}(W)$ is the union of disjoint open subsets $\{V_j\}_{j \in J}$, with the property, that the restriction of p to each subset V_j is a homeomorphism.

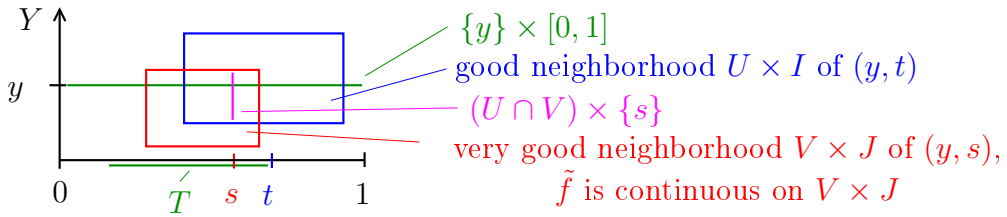
Now we want to show that there exists a $j \in J$ with $\widetilde{f}(U \times I) \subset V_j$. We choose a $y \in U$. Then there exists a unique $j \in J$ such that $\widetilde{f}(y,t) \in V_j$. Since $\widetilde{f}$ is continuous $U \times \{t\}$ and since U is connected it follows from Lemma 2.35[494] that $\widetilde{f}(U \times \{t\}) \subset V_j$. Now let $z \in U$. We just showed that $\widetilde{f}(z,t) \in V_j$. By the construction of $\widetilde{f}$ the map $\widetilde{f}$ is continuous on $\{z\} \times I$. Since I is connected it follows again from Lemma 2.35 that $\widetilde{f}(\{z\} \times I) \subset V_j$. We have thus shown that $\widetilde{f}(U \times I) \subset V_i$. This part of the argument is sketched in the figure below.

We denote by $p_j \colon V_j \to W$ the homeomorphism which is given by the restriction of p to V_j. Since $\widetilde{f}(U \times I) \subset V_j$ it follows that on $U \times I$ the map $\widetilde{f}$ is given by $\widetilde{f} = p_j^{-1} \circ f$. In particular the map $\widetilde{f}$ is a composition of continuous maps, so it is continuous on $U \times I$. ⊞

Claim. Let $y \in Y$. We consider

$$T \;:=\; \{t \in [0,1] \,|\, \text{there exists a very good neighborhood of } (y,t)\}.$$

[494] We apply Lemma 2.35 to the continuous map $U \times \{t\} \to p^{-1}(W)$ from the connected set U to the set $p^{-1}(W)$ with components V_j, $j \in J$.



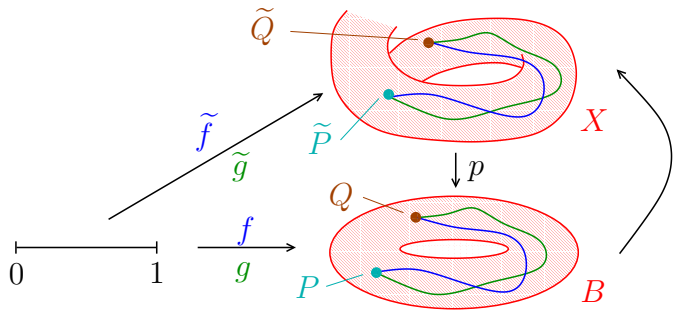
We claim that $T = [0,1]$.

Proof. Thus let $y \in Y$. Since $[0,1]$ is connected it suffices to show the following three statements:

(1) $T \neq \varnothing$,
(2) T is open, and
(3) T is closed.

Now we will prove these three statements:

(1) As we pointed out above, every point in $Y \times I$, in particular the point $(y,0)$, admits a good neighborhood. By our hypothesis $\widetilde{f}$ is continuous on $Y \times \{0\}$. It follows that the good neighborhood is in fact very good.
(2) It is easy to see that T is open. Indeed, suppose that we are given a very good neighborhood $U \times I$ of (y,t). Then $U \times I$ is also a very good neighborhood for any $(y,s) \in U \times I$. Therefore the open neighborhood I of t also lies in T.
(3) It remains to show that T is closed. Put differently, we need to show that T equals its closure $\overline{T}$. Thus let $t \in \overline{T}$. As we already pointed out, there exists a good neighborhood $U \times I$ of (y,t). Since $t \in \overline{T}$ there exists an $s \in T \cap I$. Since $s \in T$ it follows from the above claim that there exists a very good open neighborhood $V \times J$ of (y,s). By the previous claim the restriction of $\widetilde{f}$ to $V \times J$ is continuous, in particular it is continuous on $(U \cap V) \times \{s\}$. We denote by W the component of $U \cap V$ that contains y. Then $W \times I$ is a very good neighborhood of (y,t). This step is illustrated in the figure below. ⊞



We have just shown that given any $y \in Y$ and any $t \in [0,1]$ there exists a very good neighborhood $U_{y,t}$ of (y,t). By the first claim the map $\widetilde{f}$ is continuous on each $U_{y,t}$. But the open subsets $U_{y,t}$ cover all of $Y \times [0,1]$. It follows from the Pasting Proposition 2.6 that $\widetilde{f}$ is continuous on $Y \times [0,1]$. ■

Corollary 48.13. Let $p\colon X \to B$ be a covering and let $f, g\colon [0,1] \to B$ be two paths. Let $\widetilde{f}, \widetilde{g}\colon [0,1] \to X$ be two lifts with the same starting point. If f and g are path-homotopic, then the endpoints of $\widetilde{f}$ and $\widetilde{g}$ agree and the paths $\widetilde{f}$ and $\widetilde{g}$ are path-homotopic.

Proof. We write $P := f(0) = g(0)$ and $Q := f(1) = g(1)$. Furthermore we denote by $\widetilde{P} := \widetilde{f}(0) = \widetilde{g}(0)$ the common starting point of the lifts and we write $\widetilde{Q} := \widetilde{f}(1)$. Let

$$\begin{array}{rccc} H\colon [0,1] \times [0,1] & \to & B \\ (t,s) & \mapsto & H(t,s) \end{array}$$

path-homotopic paths in B
lift to path-homotopic paths in X

be a path-homotopy between the paths f and g. As a reminder, H is a map such that

$$\begin{array}{lllllllll} & H(t,0) & = & f(t) & \text{and} & H(t,1) & = & g(t) & \text{for all } t \in [0,1], \\ \text{and such that} & H(0,s) & = & P & \text{and} & H(1,s) & = & Q & \text{for all } s \in [0,1]. \end{array}$$

On $\{0\} \times [0,1]$ we consider the lift $\widetilde{H}$ of H which is given by $\widetilde{H}(0,s) = \widetilde{P}$. Furthermore we denote by $\widetilde{H}\colon [0,1] \times [0,1] \to X$ the map which is defined as follows: for each $s \in [0,1]$ the path $t \mapsto \widetilde{H}(t,s)$ is the unique lift of the path $t \mapsto H(t,s)$ to the starting point $\widetilde{P}$ lift. According to the Path-Homotopy Lifting Proposition 48.12 the map $\widetilde{H}$ is in fact continuous. By definition of $\widetilde{H}$ we have

$$\widetilde{H}(t,0) = \widetilde{f}(t) \quad \text{and} \quad \widetilde{H}(t,1) = \widetilde{g}(t) \text{ for all } t \in [0,1],$$

For each $s \in [0,1]$ we have $p(\widetilde{H}(1,s)) = Q$. Since $\widetilde{H}$ is continuous we obtain a map

$$\begin{array}{ccc} [0,1] & \to & p^{-1}(Q) \subset X \\ s & \mapsto & \widetilde{H}(1,s). \end{array}$$

Since $[0,1]$ is connected it follows from the Connected-to-Discrete Lemma 2.27 and Lemma 48.3 that $\widetilde{H}(1,s) = \widetilde{Q}$ for all $s \in [0,1]$. In particular we obtain that

$$\widetilde{f}(1) = \widetilde{H}(1,0) = \widetilde{Q} = \widetilde{H}(1,1) = \widetilde{g}(1).$$

Thus it follows that $\widetilde{H}$ is indeed a path-homotopy between the paths $\widetilde{f}$ and $\widetilde{g}$. ■

Definition. Let $p\colon X \to B$ be a map between topological spaces and let $x_0 \in X$ and $b_0 \in B$. We say a map $p\colon X \to B$ is a covering of pointed topological spaces, if $p\colon X \to B$ is a covering and if $p(x_0) = b_0$.

Corollary 48.14. For any covering $p\colon (X,x_0) \to (B,b_0)$ of pointed topological spaces the induced map $p_*\colon \pi_1(X,x_0) \to \pi_1(B,b_0)$ is a monomorphism.

Proof. We have[495]

$$\begin{array}{l} [f] \in \ker\left(\pi_1(X,x_0) \xrightarrow{p_*} \pi_1(B,b_0)\right) \implies [p \circ f] = e \in \pi_1(B,b_0) \implies p \circ f \simeq e_{b_0} \\ \qquad\qquad \implies f \simeq e_{x_0} \implies [f] = e \in \pi_1(X,x_0). \end{array}$$

by Corollary 48.13, since f is the lift of $p \circ f$ and e_{x_0} is the lift of e_{b_0} to the starting point x_0

■

[495] We use the notation from page 1053: for $y \in Y$ we denote by e_y the constant path $e_y(t) := x$, $t \in [0,1]$.

Example. In Question 48.2 (1) we had asked whether there exists a covering map from the torus $S^1 \times S^1$ to the sphere S^2. By the Sphere-π_1-Proposition 47.13 we know that $\pi_1(S^2) = 0$ whereas we saw on page 1062 that $\pi_1(S^1 \times S^1)$ is non-trivial. Using Corollary 48.14 we can now answer Question 48.2 (1) in the negative: there is no covering map from $S^1 \times S^1$ to S^2.

We conclude the section with the following lemma.

Lemma 48.15. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces.

(1) Let f be a loop in (B, b_0). We denote by $\widetilde{f}$ the lift of f to the starting point x_0. Then the following holds:

$$\widetilde{f} \text{ is a loop in } (X, x_0) \iff [f] \text{ lies in } p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0).$$

In particular, if $\widetilde{f}$ is not a loop in (X, x_0), then $[f]$ is a non-trivial element of $\pi_1(B, b_0)$.

(2) Now we suppose that X is simply connected. Let f and g loops in (B, b_0) and let $\widetilde{f}$ and $\widetilde{g}$ be the lifts of f and g to the starting point x_0. Then the following holds:

$$f \text{ and } g \text{ are path-homotopic loops} \iff \text{the endpoints of } \widetilde{f} \text{ and } \widetilde{g} \text{ agree.}$$

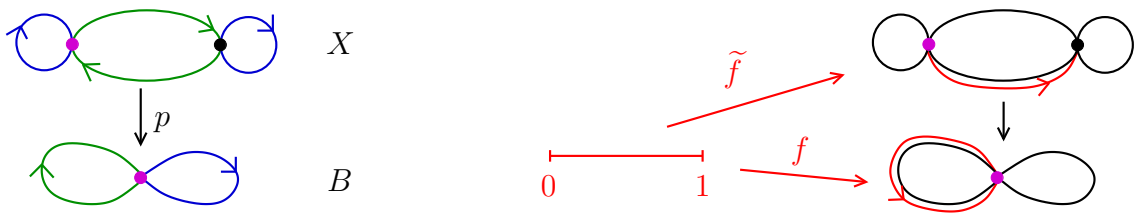
(3) If X is path-connected, then $[X : B] = [\pi_1(B, b_0) : p_*(\pi_1(X, x_0))]$.

Remark. In Exercise 48.11 we will use Lemma 48.15 (3) to answer Question 48.2 (2) in the negative.

Proof.

(1) We prove the "$\Rightarrow$"-direction. So let f be a loop in (B, b_0). We denote by $\widetilde{f}$ the lift of f to the starting point x_0. If $\widetilde{f}$ is a loop in (X, x_0), then it defines an element in $\pi_1(X, x_0)$ and we have $[f] = [p \circ \widetilde{f}] = p_*([\widetilde{f}]) \in p_*(\pi_1(X, x_0))$. The proof of the "$\Leftarrow$"-direction is Exercise 48.10.[496]

(2) The "$\Rightarrow$"-direction is an immediate consequence of Corollary 48.13. The proof of the "$\Leftarrow$"-direction is done once again in Exercise 48.10. For that direction we need that X is simply connected.



(3) This statement is proved in Exercise 48.10. ∎

Example. The last sentence of Lemma 48.15 (1) can at times be surprisingly useful for showing that a given element in a fundamental group. As proof of concept, we consider the pointed topological space (B, b_0) and we show a loop $f\colon [0, 1] \to B$ shown in the figure below. We also show a covering $p\colon (X, x_0) \to (B, b_0)$ of pointed topological spaces together with the lift $\widetilde{f}$ of f to the starting point x_0. Since $\widetilde{f}$ is not a loop we see that $[f] \in \pi_1(B, b_0)$ is non-trivial. In Exercise 48.12 we will use the same approach to show that $\pi_1(B, b_0)$ is actually non-abelian.

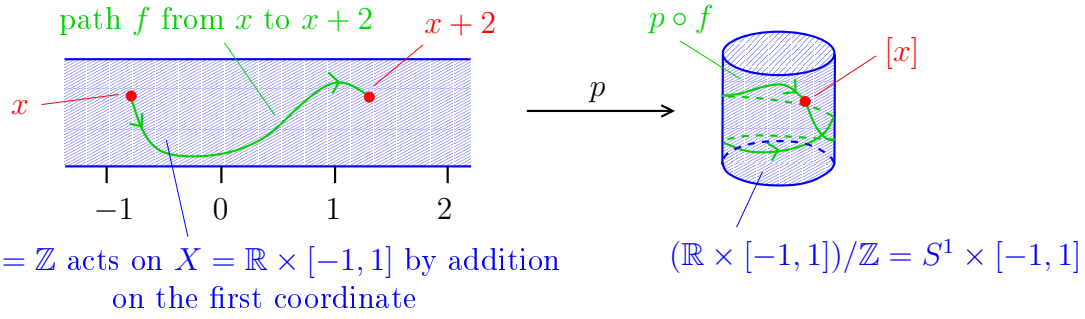
48.5. Group actions and fundamental groups.

The following proposition finally allows us to determine many fundamental groups. This proposition is the reward for the many rather theoretical results of the previous sections.

[496] Note that $[f]$ lies in $p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0)$ means that there exists a loop g in (X, x_0) such that $p \circ g$ is *path-homotopic* to f. A priori it does not mean that there exists a loop g with $p \circ g = f$.

Theorem 48.16. (Fundamental Group-via-Actions Theorem) Let X be a topological space and let G be a group which acts continuously and discretely on X. We choose an $x \in X$. We denote by $p\colon X \to X/G$ the natural projection .

(1) If X is simply connected, then the map



$$\begin{array}{rcl} G & \to & \pi_1(X/G,[x]) \\ g & \mapsto & [p \circ (\text{path in } X \text{ from } x \text{ to } g \cdot x)] \end{array}$$

is a well-defined isomorphism of groups. In particular we have $\pi_1(X/G) \cong G$.

(2) Regardless of whether or not X is simply connected, the subgroup $p_*(\pi_1(X,x))$ is normal in $\pi_1(X/G,[x])$ and the map

$$\begin{array}{rcl} G & \to & \pi_1(X/G,[x])/p_*(\pi_1(X,x)) \\ g & \mapsto & [p \circ (\text{path in } X \text{ from } x \text{ to } g \cdot x)] \end{array}$$

is a well-defined isomorphism of groups.

Before we provide the proof of the Fundamental Group-via-Actions Theorem 48.16, let us impatiently use it to finally confirm our suspicion that the fundamental group of S^1 is isomorphic to $\mathbb{Z}$.

Proposition 48.17.

(1) The maps

$$\Phi\colon \begin{array}{rcl} \mathbb{Z} & \to & \pi_1(\mathbb{R}/\mathbb{Z},[0]) \\ n & \mapsto & \underbrace{\left[\begin{array}{rcl} [0,1] & \to & \mathbb{R}/\mathbb{Z} \\ t & \mapsto & p(nt) = [nt] \end{array}\right]}_{\substack{\text{the map } t \mapsto nt \text{ is a} \\ \text{path from } 0 \text{ to } 0+n}} \end{array}$$

and

$$\Psi\colon \begin{array}{rcl} \mathbb{Z} & \to & \pi_1(S^1,1) \\ n & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & S^1 \\ t & \mapsto & \exp(2\pi i n t) \end{array}\right] \end{array}$$

are isomorphisms of groups.

(2) Let $n \in \mathbb{N}$. We consider the map $f\colon S^1 \to S^1$ that is given by $z \mapsto z^n$. The induced map on $\pi_1(S^1, 1)$ is given by multiplication by n.
(3) The map
$$\begin{array}{rccc} \Theta\colon \pi_1(S^1,1) & \to & \mathbb{Z} \\ [\gamma] & \mapsto & \frac{1}{2\pi \mathrm{i}} \int\limits_\gamma \frac{1}{z}\, dz \end{array}$$
is an isomorphism.

Proof.

(1) We consider the action of $G = \mathbb{Z}$ on the simply connected space $X = \mathbb{R}$. We denote by $p\colon \mathbb{R} \to \mathbb{R}/\mathbb{Z}$ the natural projection . It follows immediately from the Fundamental Group-via-Actions Theorem 48.16 that the given map $\Phi\colon \mathbb{Z} \to \pi_1(\mathbb{R}/\mathbb{Z}, [0])$ is an isomorphism. We denote by $\phi\colon \mathbb{R}/\mathbb{Z} \to S^1$ the homeomorphism given by $\phi([t]) = \exp(2\pi \mathrm{i} t)$. If we compose the above isomorphism with the isomorphism $\phi_*\colon \pi_1(\mathbb{R}/\mathbb{Z}, [0]) \to \pi_1(S^1, 1)$, then we see that the second map $\Psi\colon \mathbb{Z} \to \pi_1(S^1, 1)$ is also an isomorphism.
(2) This statement follows easily from the definitions. To practice the definitions we will prove this statement in Exercise 48.16.
(3) It is straightforward to see that $\Theta \circ \Psi\colon \mathbb{Z} \to \pi_1(S^1, 1) \to \mathbb{Z}$ is the identity. By (1) the first map Ψ is an isomorphism. Thus $\Theta = \Phi^{-1}$ is also an isomorphism. ■

We will provide many more examples for the Fundamental Group-via-Actions Theorem 48.16 immediately after the proof of the Fundamental Group-via-Actions Theorem 48.16.

Proof of the Fundamental Group-via-Actions Theorem 48.16. To simplify the discussion we only provide the proof of the Fundamental Group-via-Actions Theorem 48.16 (1). The proof of the Fundamental Group-via-Actions Theorem 48.16 (2) is almost the same. We leave it to the reader to make the necessary modifications.

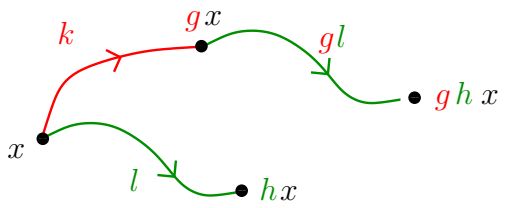
Let X be a simply connected space and let G be a group which acts continuously and discretely on X.[497] We choose an $x \in X$. We denote by $p\colon X \to X/G$ the natural projection . We consider the map
$$\begin{array}{rccc} \Phi\colon G & \to & \pi_1(X/G, [x]) \\ g & \mapsto & [p \circ (\text{path in } X \text{ from } x \text{ to } gx)]. \end{array}$$

We need to prove the following four statements:

(1) Φ is well-defined,
(2) Φ is a group homomorphism,
(3) Φ is surjective,
(4) Φ is injective.

Now we provide the proofs for these four claims.

(1) We first show that the map Φ is well-defined. Let $g \in G$. Since X is in particular path-connected there exists a path from x to gx. Now let f be an arbitrary path in X from x to gx. From $p(x) = [x] = [gx] = p(gx)$ it follows that $p \circ f$ is a loop in $(X/G, [x])$. In particular $p \circ f$ does indeed define an element in $\pi_1(X/G, [x])$.



Now we need to show that this element does not depend on the choice of f. So let f' be another path in X from x to gx. Since X is simply connected it follows from Lemma 47.12 that the paths f and f' are path-homotopic in X, i.e. there exists

[497] It is perhaps helpful to read the proof with the example of the action of $\mathbb{Z}^n$ on $\mathbb{R}^n$ in mind.

a path-homotopy $H\colon [0,1]\times[0,1]\to X$ from f to f'. But then $p\circ H\colon [0,1]\times[0,1]\to X/G$ is a path-homotopy from the loop $p\circ f$ to the loop $p\circ f'$. This shows that the map Φ is well-defined.

(2) Now we show that Φ is a group homomorphism. Let $g,h\in G$ and pick be a path k from x to gx and pick a path l from x to hx. Then gl[498] is a path from gx to ghx and $k*gl$ is a path from x to ghx. It follows that

$$\Phi(gh) \underset{\substack{\uparrow\\ \text{since } k*gl \text{ is a path from } x \text{ to } ghx}}{=} [p\circ(k*gl)] = [(p\circ k)*(p\circ gl)] \underset{\substack{\downarrow\\ \text{since } p(gx)=p(x)\in X/G \text{ for all } x\in X}}{=} [(p\circ k)*(p\circ l)]$$
$$= [p\circ k]\cdot[p\circ l] = \Phi(g)\cdot\Phi(h).$$
$$\text{definition of } \cdot \text{ in } \pi_1(X/G,[x])\uparrow$$

Before we continue let us recall that according to the Actions-Covering Proposition 48.9 the projection $p\colon X\to X/G$ is a covering.

(3) Now we prove that Φ is surjective. We choose an arbitrary element $c\in\pi_1(X/G,[x])$ and represent it by a loop f in $(X/G,[x])$. According to Proposition 48.11 there exists a lift $\widetilde{f}\colon [0,1]\to X$ of the path f to the starting point x. By definition we have $p\circ\widetilde{f}=f$. In particular we obtain for the endpoint of $\widetilde{f}$ that $p(\widetilde{f}(1))=[x]$, therefore it follows that $\widetilde{f}(1)=gx$ for some $g\in G$. Thus we have proved that

$$\Phi(g) = \big[p\circ(\text{path from } x \text{ to } gx)\big] = [p\circ\widetilde{f}] = [f] = c.$$

(4) We conclude the proof of the proposition by showing that Φ is injective. Let $g\in G$. Then the following holds:

$$\Phi(g)=e \implies [p\circ(\text{path } f \text{ from } x \text{ to } gx)]=e\in\pi_1(X/G,[x])$$
$$\implies p\circ f\simeq e_{[x]} \text{ in } X/G$$
$$\underset{\substack{\uparrow\\ \text{by Corollary 48.13, since } f \text{ is a lift of } p\circ f \text{ and } e_x\\ \text{is a lift of } e_{[x]} \text{ to the starting point } x}}{\implies} f(1)=e_x(1) \implies gx=x \underset{\substack{\uparrow\\ \text{since the action is discrete,}\\ \text{hence free}}}{\implies} g=e.$$

This shows that Φ is indeed injective.

We have thus shown that Φ is a well-defined isomorphism. ■

Now we can determine the fundamental groups of many of the topological spaces that we have encountered so far.

[498] Here gl denotes the path $[0,1]\to X$ that is given by $t\mapsto g\cdot l(t)$.

Corollary 48.18. We have the following isomorphisms of fundamental groups

$$\begin{array}{lrcll}
\text{(A)} & \pi_1(\text{n-dimensional torus}) & = & \pi_1(\mathbb{R}^n/\mathbb{Z}^n) & \cong \mathbb{Z}^n \\
& \text{in particular} & & & \\
& \pi_1(S^1) & = & \pi_1(\mathbb{R}/\mathbb{Z}) & \cong \mathbb{Z}, \\
\text{(B)} & \text{for any } n \neq 0,1 & & & \\
& \pi_1(\text{real projective space } \mathbb{R}\mathrm{P}^n) & = & \pi_1(S^n/\{\pm 1\}) & \cong \mathbb{Z}_2, \\
\text{(C)} & \pi_1(\text{Möbius band }) & = & \pi_1((\mathbb{R}\times[-1,1])/\mathbb{Z}) & \cong \mathbb{Z}, \\
\text{(D)} & \pi_1(\text{lens space } L(p,q)) & = & \pi_1(S^3/\mathbb{Z}_p) & \cong \mathbb{Z}_p.
\end{array}$$

Proof. By the Sphere-π_1-Proposition 47.13 we know that for any $n \geq 2$ the sphere S^n is simply connected. Furthermore we know by the discussion on page 1055 that $\mathbb{R}^n$, $n \geq 1$, and that the strip $\mathbb{R}\times[-1,1]$ are simply connected. We saw on page 1074 that all the actions are discrete. The actions are of course also continuous. The corollary is now an immediate consequence of the Fundamental Group-via-Actions Theorem 48.16. ■

Thus we have now finally determined the fundamental groups of many spaces. In the Sphere-π_1-Proposition 47.13 we saw that $\pi_1(S^2) = 0$ whereas we have now seen that $\pi_1(S^1 \times S^1) \cong \mathbb{Z}^2$. The fundamental groups are not isomorphic, hence the sphere S^2 and the torus $S^1 \times S^1$ are not homeomorphic.

We also obtained a partial answer to Question 48.7: if two lens spaces $L(p,q)$ and $L(\widetilde{p},\widetilde{q})$ are homeomorphic, then $p = \widetilde{p}$. But as of right now we cannot say anything about the parameters q and $\widetilde{q}$.

Examples. the Fundamental Group-via-Actions Theorem 48.16 not only gives us the fact that $\pi_1(X/G)$ is isomorphic to the group G, but it also gives us an explicit isomorphism. Now we will study this isomorphism in two examples to explicitly determine non-trivial elements in the fundamental group of the torus and the real projective space.

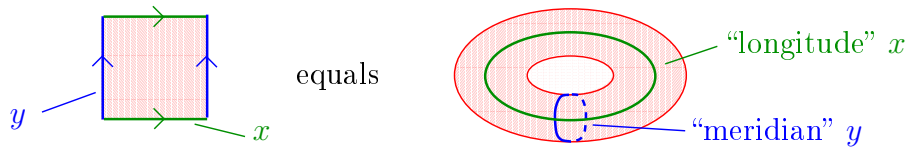
(1) As a reminder, the torus is defined as[499]

$$T \;=\; \mathbb{R}^2/\mathbb{Z}^2 \;=\; [0,1]\times[0,1]/(x,0)\sim(x,1) \text{ and } (0,y)\sim(1,y).$$

The explicit isomorphism of the Fundamental Group-via-Actions Theorem 48.16

$$\Phi\colon \mathbb{Z}^2 \;\to\; \pi_1(T,(0,0))$$

assumes in particular the following values



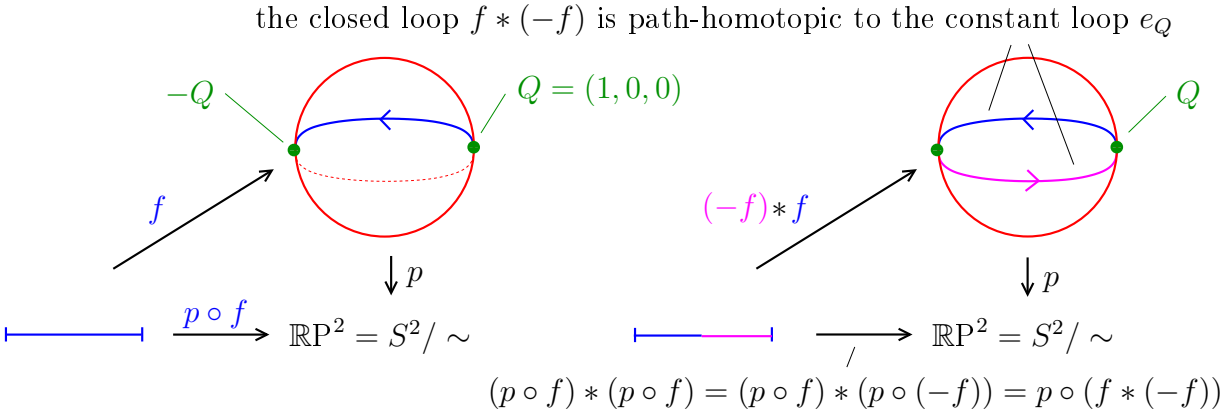
$$\Phi((1,0)) \;=\; x \;:=\; \underbrace{\left[\begin{array}{ccc} [0,1] & \to & ([0,1]\times[0,1])/\!\sim \\ t & \mapsto & [(t,0)] \end{array}\right]}_{t\mapsto(t,0) \text{ is a path from } (0,0) \text{ to } (1,0)}$$

and

$$\Phi((0,1)) \;=\; y \;:=\; \underbrace{\left[\begin{array}{ccc} [0,1] & \to & ([0,1]\times[0,1])/\!\sim \\ t & \mapsto & [(0,t)] \end{array}\right]}_{t\mapsto(0,t) \text{ is a path from } (0,0) \text{ to } (0,1)}.$$

In the description of the torus as a subset of $\mathbb{R}^3$, see the figure below, these two loops correspond to the "longitude" and the "meridian".

[499] Here we are slightly generous in our usage of the equality sign. More precisely, strictly speaking $\mathbb{R}^2/\mathbb{Z}^2$ is not the same as $([0,1]\times[0,1])/\!\sim$. But there exists a canonical homeomorphism between these two spaces that we use to identify these spaces.



(2) Now we consider the real projective space $\mathbb{R}\mathrm{P}^2 = S^2/\{\pm 1\} = S^2/x \sim -x$ and as usual we denote by $p\colon S^2 \to \mathbb{R}\mathrm{P}^2$ the projection. We put $Q := (1,0,0)$. We consider the following path in S^2:

$$\begin{array}{rcl} f\colon [0,1] & \to & S^2 \\ t & \mapsto & (\cos(\pi t), \sin(\pi t), 0). \end{array}$$

This is a path from Q to $-Q = (-1)\cdot Q$. Since -1 is the one non-trivial element of the group $G = \{\pm 1\}$ it follows from the explicit isomorphism of the Fundamental Group-via-Actions Theorem 48.16 that the equivalence class of $p \circ f$ is precisely the one non-trivial element of the fundamental group $\pi_1(\mathbb{R}\mathrm{P}^2, p(Q)) \cong \{\pm 1\}$.[500] Since $\pi_1(\mathbb{R}\mathrm{P}^2, p(Q))$ is isomorphic to $\mathbb{Z}_2$ we see that $p \circ f$ represents an element of order 2, i.e. $(p \circ f) * (p \circ f)$ represents the trivial element in the fundamental group. Put differently, $(p \circ f) * (p \circ f)$ is null-homotopic. This one can see quite explicitly. More precisely, we have

$$\begin{aligned} [p \circ f] \cdot [p \circ f] &= [(p \circ f) * (p \circ f)] = [(p \circ (-f)) * (p \circ f)] = [p \circ (f * (-f))] \\ &= \left[p \circ \underbrace{\left(\begin{array}{rcl} f\colon [0,1] & \to & S^2 \\ t & \mapsto & (\cos(2\pi t), \sin(2\pi t), 0) \end{array} \right)}_{\text{loop } g \text{ in } S^2} \right]. \end{aligned}$$

The loop g in (S^2, Q) is clearly null-homotopic.[501] But then the loop $p \circ g$ is also null-homotopic. This example is illustrated in the figure below.

[500] In particular we have now shown that the loop in $\mathbb{R}\mathrm{P}^2$ given on page 1049 is not null-homotopic.

[501] More precisely, it is straightforward to write down an explicit path-homotopy from g to the constant path e_Q. Alternatively one can also deduce that g is null-homotopic from our calculation $\pi_1(S^2, Q) = 0$.

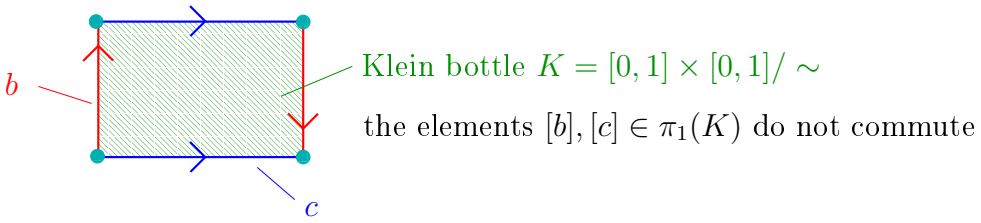
Example. We consider the Klein bottle. Recall that on page 1074 we introduced the group G that is given by all self-homeomorphisms of $\mathbb{R}^2$ that can be written as concatenations of the two self-homeomorphisms

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1) \end{array}$$

and their inverses. In Exercise 48.8 we will see G acts discretely on $\mathbb{R}^2$. Also recall we saw in Exercise 25.11 that $\mathbb{R}^2/G$ is homeomorphic to the Klein bottle. It follows from the Fundamental Group-via-Actions Theorem 48.16 that

$$\pi_1(\text{Klein bottle}) \;\cong\; G = \text{ group that is generated by the homeomorphisms } A \text{ and } B.$$

The maps A and B do not commute. Indeed, the map $A \circ B\colon \mathbb{R}^2 \to \mathbb{R}^2$ is given by



$$(x,y) \;\mapsto\; (x+1, (1-(y+1))) \;=\; (x+1, -y)$$

whereas the map $B \circ A\colon \mathbb{R}^2 \to \mathbb{R}^2$ is given by

$$(x,y) \;\mapsto\; (x+1, (1-y)+1) \;=\; (x+1, 2-y).$$

Thus we see that the fundamental group of the Klein bottle is a non-abelian group.

In the figure below we show the two elements b and c of the fundamental group of the Klein bottle $K = ([0,1] \times [0,1])/\sim$ which correspond to B and $C = B^{-1} \circ A$ under the isomorphism of the Fundamental Group-via-Actions Theorem 48.16 and the homeomorphism from Exercise 25.11. Since the two homeomorphisms $B(x,y) = (x, y+1)$ and $C(x,y) = (x+1, -y)$ do not commute, the corresponding elements $[b]$ and $[c]$ of $\pi_1(K)$ do not commute either.

The previous example showed that fundamental groups can be non-abelian groups. In fact, as we will see later in Chapter 52, many, actually arguably "most" fundamental groups are non-abelian. This will pose several major problems. For example, what is a good way to describe a non-abelian group? How can we decide whether or not two non-abelian groups are isomorphic?

We conclude this section with a more unusual topological space. Namely we remark in Exercise 48.15 we will use the Fundamental Group-via-Actions Theorem 48.16 to show that the fundamental group of the pseudocircle, i.e. of the topological space $X = \{A, B, C, D\}$ from page 141, is isomorphic to $\mathbb{Z}$. In particular we show that the loop given on page 141 is not null-homotopic. This answers the question we had posed on page 1049.

48.6. **The fundamental group of the product of two topological spaces.** The next proposition says that the fundamental groups of the product $A \times B$ of two topological spaces A and B is the direct product of the fundamental groups of A and B. Before we state the proposition explicitly we recall the definition of the direct product of two groups.

Definition. Let G and H two groups. We can form the cartesian product

$$G \times H \;:=\; \{(g,h) \,|\, g \in G \text{ and } h \in H\}.$$

This is again a group with the group structure given by

$$(g_1,h_1)\cdot(g_2,h_2) \;:=\; (g_1g_2, h_1h_2)$$

for $g_1, g_2 \in G$ and $h_1, h_2 \in H$. We call the group $G \times H$ the direct product of the groups G and H.

We start out with the following lemma, which strictly speaking we will not need, but which is worth knowing.

Lemma 48.19. Let $\varphi_1 \colon G_1 \to \pi$ and $\varphi_2 \colon G_2 \to \pi$ be two group homomorphisms. If for every $g_1 \in G_1$ and $g_2 \in G_2$ the images $\varphi_1(g_1) \in \pi$ and $\varphi_2(g_2) \in \pi$ commute, i.e. if we have $\varphi_1(g_1)\cdot\varphi_2(g_2) = \varphi_2(g_2)\cdot\varphi_1(g_1)$, then the map

$$\begin{array}{rcl} \varphi_1 \times \varphi_2 \colon G_1 \times G_2 & \to & \pi \\ (g_1,g_2) & \mapsto & \varphi_1(g_1)\cdot\varphi_2(g_2) \end{array}$$

is a homomorphism.[502]

Proof. We write $\Phi = \varphi_1 \times \varphi_2$. Let $g_1, g_1' \in G_1$ and let $g_2, g_2' \in G_2$. We have

$$\begin{array}{rcl} \Phi(g_1,g_2)\cdot\Phi(g_1',g_2') & = & \varphi_1(g_1)\cdot\varphi_2(g_2)\cdot\varphi_1(g_1')\cdot\varphi_2(g_2') \\ & = & \varphi_1(g_1)\cdot\varphi_1(g_1')\cdot\varphi_2(g_2)\cdot\varphi_2(g_2') \quad = \quad \varphi_1(g_1g_1')\cdot\varphi_2(g_2g_2') \\ & \uparrow & \quad = \quad \Phi(g_1g_1', g_2g_2'). \\ & \text{by our hypothesis} & \end{array}$$

■

Now we can formulate the promised proposition.

Proposition 48.20. (Fundamental Group-of-Product Proposition) Let A and B be two topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the inclusion maps

$$\begin{array}{rcl} i \colon A & \to & A \times B \\ a & \mapsto & (a,b_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} j \colon B & \to & A \times B \\ b & \mapsto & (a_0,b) \end{array}$$

and we consider the projection s

$$\begin{array}{rcl} p \colon A \times B & \to & A \\ (a,b) & \mapsto & a \end{array} \quad \text{and} \quad \begin{array}{rcl} q \colon A \times B & \to & B \\ (a,b) & \mapsto & b. \end{array}$$

The maps

$$\begin{array}{rcl} \Phi \colon \pi_1(A,a_0) \times \pi_1(B,b_0) & \to & \pi_1(A\times B,(a_0,b_0)) \\ (x,y) & \mapsto & i_*(x)\cdot j_*(y) \end{array}$$

and

$$\begin{array}{rcl} \Psi \colon \pi_1(A\times B,(a_0,b_0)) & \to & \pi_1(A,a_0)\times\pi_1(B,b_0) \\ z & \mapsto & (p_*(z),q_*(z)) \end{array}$$

are both homomorphisms[503] and they are inverses of one another, in particular both are isomorphisms.

---

[502] In fact the converse also holds, if $\varphi_1 \times \varphi_2$ is a homomorphism, then for every $g_1 \in G_1$ and $g_2 \in G_2$ the images $\varphi_1(g_1) \in \pi$ and $\varphi_2(g_2) \in \pi$ commute. Why is that?

[503] Note that a priori it is not clear that Φ is a homomorphism since it is not clear whether the hypothesis of Lemma 48.19 is satisfied.

Example. It follows from the Fundamental Group-of-Product Proposition 48.20 and Corollary 48.18 that

$$\pi_1(S^1 \times L(p,q)) \;\cong\; \pi_1(S^1) \times \pi_1(L(p,q)) \;\cong\; \mathbb{Z} \times \mathbb{Z}_p.$$

Similarly, we see, using the Sphere-π_1-Proposition 47.13, that for any $k \geq 2$ we have

$$\pi_1(S^1 \times S^k) \;\cong\; \pi_1(S^1) \times \pi_1(S^k) \;\cong\; \mathbb{Z} \times 0 \;\cong\; \mathbb{Z}.$$

Of course we can also apply the Fundamental Group-of-Product Proposition 48.20 several times and we see once again that

$$\pi_1\big(\underbrace{S^1 \times \cdots \times S^1}_{n \text{ times}}\big) \;\cong\; \underbrace{\pi_1(S^1) \times \ldots \times \pi_1(S^1)}_{n \text{ times}} \;\cong\; \underbrace{\mathbb{Z} \times \cdots \times \mathbb{Z}}_{n \text{ times}} \;\cong\; \mathbb{Z}^n.$$

Finally it follows from Propositions 47.13 and 48.20 that for any $k, l \geq 2$ we have

$$\pi_1(S^k \times S^l) \;\cong\; \pi_1(S^k) \times \pi_1(S^l) \;\cong\; 0 \times 0 \;=\; 0.$$

In particular we see that the fundamental group cannot distinguish the products of spheres of dimension ≥ 2. For example at the moment we cannot show that the two 6-dimensional smooth manifolds $S^3 \times S^3$ and $S^2 \times S^2 \times S^2$ are not homeomorphic.

In the proof of the Fundamental Group-of-Product Proposition 48.20 we will need the following purely group-theoretic lemma.

Proof of the Fundamental Group-of-Product Proposition 48.20. It is clear that

$$\Psi = (p_*, q_*)\colon \pi_1(A \times B, (a_0, b_0)) \;\to\; \pi_1(A, a_0) \times \pi_1(B, b_0)$$

is a homomorphism. Thus it suffices to show that Φ and Ψ are inverses of one another. Once we have shown that, it follows for free that Φ is also a homomorphism.

To show that Φ and Ψ are inverses of one another we introduce another map, namely we consider[504]

$$\begin{array}{rcl} \Theta\colon \pi_1(A, a_0) \times \pi_1(B, b_0) & \to & \pi_1(A \times B, (a_0, b_0)) \\ ([f\colon (S^1, 1) \to (A, a_0)], [g\colon (S^1, 1) \to (B, b_0)]) & \mapsto & \left[\begin{array}{rcl} (S^1, 1) & \to & (A \times B, (a_0, b_0)) \\ z & \mapsto & (f(z), g(z)) \end{array}\right]. \end{array}$$

It is almost a tautology that Θ and Ψ are inverses of one another. Thus it remains to prove the following claim.

Claim. The two maps $\Phi, \Theta\colon \pi_1(A, a_0) \times \pi_1(B, b_0) \to \pi_1(A \times B, (a_0, b_0))$ agree.

Proof. We use the convention from page 1050 to change our view of fundamental groups. Thus let $f\colon [0,1] \to A$ be a loop in (A, a_0) and $g\colon [0,1] \to B$ be a loop in (B, b_0). We need to show that

$$i_*([f]) \cdot j_*([g]) \;=\; [(t \mapsto (f(t), g(t))] \;\in\; \pi_1(A \times B, (a_0, b_0).$$

In other words, we need to show that the two loops

$$\begin{array}{rcl} [0,1] & \to & A \times B \\ t & \mapsto & \begin{cases} (f(2t), b_0), & \text{if } t \in [0, \frac{1}{2}] \\ (a_0, g(2t-1)), & \text{if } t \in [\frac{1}{2}, 1] \end{cases} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} [0,1] & \to & A \times B \\ t & \mapsto & (f(t), g(t)) \end{array}$$

[504] One can easily verify that Θ is well-defined.

are path-homotopic. In fact an explicit path-homotopy is given by the map[505]

$$\begin{array}{rcl} F\colon [0,1]\times[0,1] & \to & A\times B \\ (t,s) & \mapsto & \begin{cases} \big(f\big(\frac{2t}{1+s}\big), g(st)\big), & \text{if } t\in[0,\frac{1}{2}] \\ \big(f(st), g\big(\frac{2t-1+s}{1+s}\big)\big), & \text{if } t\in[\frac{1}{2},1]. \end{cases} \end{array}$$ ■

Summarizing we have now finally managed to calculate many non-trivial fundamental groups. Nonetheless, the list of topological spaces for which we cannot yet calculate the fundamental group is still pretty long, it includes

(1) topological graphs,
(2) knot complements,
(3) the complement of more than one point in $\mathbb{C}$, e.g. $\mathbb{C}\setminus\{0,1\}$,
(4) surfaces of genus ≥ 2.

In the following chapters we will introduce more methods for determining the fundamental group of a given topological space. But first we give in the next section two applications of our results.

48.7. The Fundamental Theorem of Algebra and the Borsuk-Ulam Theorem ❀.

As a first application of our methods we give another proof of the Fundamental Theorem of Algebra. Somewhat surprisingly, contrary to the standard proof [**Lang1999**, Corollary III.7.6], this proof does not make use of complex analysis.

Theorem 26.3. (Fundamental Theorem of Algebra) ❀ Every nonconstant polynomial with coefficients in $\mathbb{C}$ has a zero in $\mathbb{C}$.

Remark. Other proofs are provided on page 704 and page 1700.

Proof. Let $q(z)$ be a polynomial with complex coefficients with $q(z)\neq 0$ for all $z\in\mathbb{C}$ with $|z|=r$. We consider the path

$$\begin{array}{rcl} f_r^{q(z)}\colon [0,1] & \to & S^1 \\ s & \mapsto & \dfrac{q(r\cdot\exp(2\pi\mathrm{i}s))/q(r)}{|q(r\cdot\exp(2\pi\mathrm{i}s))/q(r)|} \end{array}$$

Note that $f_r^{q(z)}(s=0)=f_r^{q(z)}(s=1)=1$, i.e. $f_r^{q(z)}$ is a loop in $(S^1,1)$. Now let

$$p(z) \;=\; a_nz^n+a_{n-1}z^{n-1}+\cdots+a_1z+a_0$$

be a polynomial of degree $n\geq 1$. We assume that $p(z)$ has no zeros in $\mathbb{C}$. For $t\in[0,1]$ we also consider the polynomial

$$p_t(z) \;:=\; a_nz^n+t(a_{n-1}z^{n-1}+\cdots+a_1z+a_0).$$

Note that $p_1(z)=p(z)$ and $p_0(z)=a_nz^n$. Since $a_n\neq 0$ there exists an $s>0$ such that[506]

$$|a_nz^n| \;>\; |a_{n-1}z^{n-1}+\cdots+a_1z+a_0|$$

for any z with $|z|=s$. This inequality implies that for any $t\in[0,1]$ and any z with $|z|=s$ we have $p_t(z)\neq 0$, i.e. $p_t(z)$ has no zeros on the circle $|z|=s$.

[505] Note that this is indeed a path-homotopy of loops.

[506] In fact we can write it down explicitly: it follows easily from the triangle inequality that any $s\in\mathbb{R}$ such that $s\cdot|a_n|>|a_{n-1}|+\cdots+|a_0|$ will work.

We obtain the following sequence of path-homotopic loops:

$$\underset{\text{follows from the definition}}{\text{constant loop at } 1} \overset{\downarrow}{=} f_0^{p(z)} \underset{\uparrow}{\simeq} f_s^{p(z)} = f_s^{p_1(z)} \underset{\uparrow}{\simeq} f_s^{p_0(z)} \overset{\downarrow}{=} \underset{\text{follows from } p_0(z)=a_nz^n}{\text{the loop } \begin{array}{ccc}[0,1] & \to & S^1\\ t & \mapsto & \exp(2\pi \mathrm{i} n t).\end{array}}$$

maps $f_r^{p(z)}$ with $r \in [0,s]$ are defined, since the polynomials $p(z)$ has no zeros they form a path-homotopy from $f_0^{p(z)}$ to $f_s^{p(z)}$

maps $f_s^{p_t(z)}$ with $t \in [0,1]$ are defined, since polynomials $p_t(z)$ have no zeros on $|z|=s$, and and they form a path-homotopy from $f_r^{p_1(z)}$ to $f_r^{p_0(z)}$

By Proposition 48.17 we had know that the loop on the right defines a non-trivial element in the fundamental group $\pi_1(S^1,1)$, but we had just shown that it is path-homotopic to the constant path. Thus we have obtained a contradiction. ■

The following theorem goes back to the Polish mathematicians Karol Borsuk (1905-1982) and Stanislaw Ulam (1909-1984).[507] It was first proved in 1932.

Theorem 48.21. (Borsuk-Ulam Theorem) For every map $f\colon S^2 \to \mathbb{R}^2$ there exists a pair of antipodal points x and $-x$ in S^2 with $f(x) = f(-x)$.

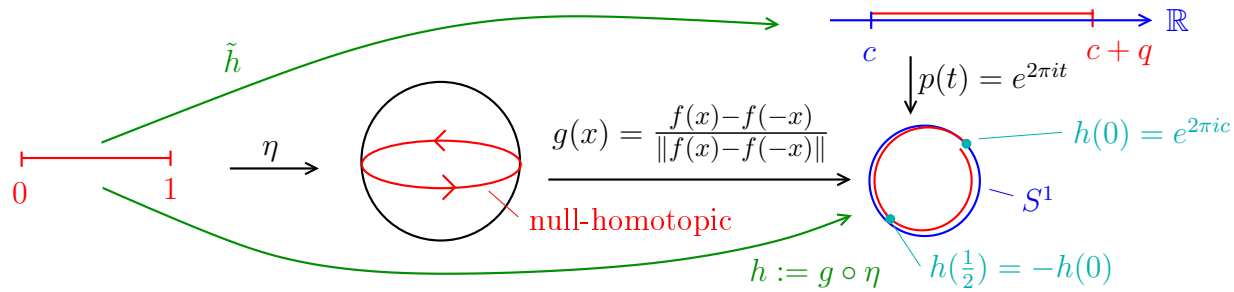
Examples.

(1) It follows from the Borsuk-Ulam Theorem that there exists pair of antipodal points on earth with the same temperature and the same barometric pressure.
(2) The Borsuk-Ulam Theorem implies in particular that there is no injective map from $S^2 \to \mathbb{R}^2$.
(3) The statement of the Borsuk-Ulam Theorem also makes sense for 2 replaced by any $n \in \mathbb{N}$. For $n = 1$ one can prove the statement using elementary methods.[508] We will address the problem for $n \geq 3$ once we have introduced homology groups.

Proof. We prove the theorem by contradiction. So suppose there exists a map $f\colon S^2 \to \mathbb{R}^2$ such that $f(x) \neq f(-x)$ for all $x \in S^2$. This allows to define the map

$$\begin{array}{rcl} g\colon S^2 & \to & S^1 \\ x & \mapsto & \frac{f(x)-f(-x)}{\|f(x)-f(-x)\|}. \end{array}$$

Note that $g(-x) = -g(x)$ for all $x \in S^2$. Now let η be the loop that is defined by



$$\begin{array}{rcl} \eta\colon [0,1] & \to & S^2 \\ s & \mapsto & \eta(s) = (\cos(2\pi s), \sin(2\pi s), 0) \end{array}$$

and let $h = g \circ \eta\colon [0,1] \to S^1$ be the composition of η with g. We pick a $c \in \mathbb{R}$ such that $h(0) = \exp(2\pi \mathrm{i} c)$. We denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto \exp(2\pi \mathrm{i} t)$, the usual covering map. We note that for $z, w \in \mathbb{R}$ we have

$$p(z) = p(w) \iff z - w \in \mathbb{Z} \quad \text{and} \quad p(z) = -p(w) \iff z - w \in \tfrac{1}{2} + \mathbb{Z}.$$

By Proposition 48.11 we can lift the path $h\colon [0,1] \to S^1$ to a path $\widetilde{h}\colon [0,1] \to \mathbb{R}$ with $\widetilde{h}(0) = c$.

[507] Ulam became much more famous through his work on the hydrogen bomb.
[508] How would you prove the statement?

Given any $s \in [0, \frac{1}{2}]$ we have

$$p\big(\widetilde{h}\big(s+\tfrac{1}{2}\big)\big) \;=\; h\big(s+\tfrac{1}{2}\big) \;=\; g\big(\eta\big(s+\tfrac{1}{2}\big)\big) \underset{\text{by the definition of } \eta}{\overset{\uparrow}{=}} g(-\eta(s)) \underset{\text{since } g(-x)=-g(x) \text{ for all } x \in S^2}{\overset{\uparrow}{=}} -g(\eta(s)) \;=\; -h(s) \;=\; -p\big(\widetilde{h}(s)\big).$$

By the above discussion of p this implies that

$$\widetilde{h}\big(s+\tfrac{1}{2}\big) - \widetilde{h}(s) \;=:\; \frac{q(s)}{2}$$

with $q(s)$ an odd integer. The map $q\colon [0, \frac{1}{2}] \to \mathbb{Z}$ is the difference of two continuous maps, hence continuous. It follows from the Connected-to-Discrete Lemma 2.27 that it is constant. We denote this constant value by q. Since q is odd it is in particular non-zero.

It follows from the above that

$$\widetilde{h}(1) \;=\; \widetilde{h}\big(\tfrac{1}{2}\big) + \tfrac{q}{2} \;=\; \widetilde{h}(0) + \tfrac{q}{2} + \tfrac{q}{2} \;=\; \widetilde{h}(0) + q.$$

Since q is non-zero we obtain from Lemma 48.15 that $h = g \circ \eta$ is not null-homotopic. But h was the composition $h = g \circ \eta\colon [0,1] \to S^2 \to S^1$. By the Sphere-$\pi_1$-Proposition 47.13 the loop η is null-homotopic in S^2 which implies by Proposition 47.15 that $h = g \circ \eta$ is null-homotopic in S^1. Thus we have obtained a contradiction. ■

Exercises for Chapter 48.

Exercise 48.1. Let $p\colon X \to B$ be a covering of topological spaces. We suppose that B is a path-connected topological space. Show that for any two points P and Q in B we have

$$\#p^{-1}(P) \;=\; \#p^{-1}(Q).$$

Exercise 48.2.

(a) Let $p\colon X \to B$ be a map between topological spaces that is two-to-one, i.e. such that for any $b \in B$ the preimage $p^{-1}(b)$ consists of precisely two points. Is p necessarily a covering map?

(b) Is the map

$$\begin{array}{ccc} \mathbb{C} & \to & \mathbb{C} \setminus \{0\} \\ z & \mapsto & \exp(z) \end{array}$$

a covering map? *Hint.* $z = x + \mathrm{i}y$ with $x, y \in \mathbb{R}$.

(c) Let $p\colon X \to B$ be a surjective map between topological spaces. Let $f\colon [0,1] \to B$ be a map. Does there always exist a lift from f to X, i.e. does there exist a map $g\colon [0,1] \to X$ such that $p \circ g = f$? Give a short justification for your answer.

Exercise 48.3.

(a) Show that there exists a map $p\colon X \to B$ be a map between topological spaces that is a local homeomorphism and that is surjective but which is not a covering map.
(b) Let $p\colon X \to B$ be a map between topological spaces that is a local homeomorphism and that is surjective. Furthermore we suppose that p is proper, i.e. we assume that the preimage of each compact set is compact. Is p necessarily a covering map?

Exercise 48.4. Let $p\colon X \to B$ be a covering of topological spaces. Show that if B is Hausdorff, then X is also Hausdorff.

Exercise 48.5. Let X, Y and Z be topological spaces and let $p\colon X \to Y$ and $q\colon Y \to Z$ be maps. Which of the following two statements are true?

(a) If $q \circ p$ is a covering map, then p is also a covering map.
(b) If $q \circ p$ is a covering map, then q is also a covering map.

Exercise 48.6. Consider the 5-fold covering map

$$\begin{array}{rcl} p\colon X = S^1 & \to & B = S^1 \\ z & \mapsto & z^5. \end{array}$$

Let $f\colon [0,1] \to B = S^1$ be the loop given by $t \mapsto \exp(2\pi \mathrm{i} kt)$. By Proposition 6.11 this loop lifts to a path $g\colon [0,1] \to X = S^1$. For which k is the lift g again a loop?

Exercise 48.7. Let $p\colon \widetilde{X} \to X$ be a covering of topological spaces.

(a) Show that for $A \subset X$ we have $\quad$ closure of $p^{-1}(A) = p^{-1}(\text{closure of } A)$
(b) Show that for $A \subset X$ we have $\quad$ interior of $p^{-1}(A) = p^{-1}(\text{interior of } A)$.

Exercise 48.8. We consider the following two self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1). \end{array}$$

We denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means

$$G = \begin{array}{c} \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}. \end{array}$$

(a) For $n \in \mathbb{Z}$, what is $A^{-n}BA^n$? (Perhaps start out with $n = 1$.)
(b) We write $C = A^2$. We denote by H the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by C and B. Does A lie in H?
Hint. Consider which self-diffeomorphisms of $\mathbb{R}^2$ are orientation-preserving.
(c) Show that any element X of G lies in H or it is of the form $G = AY$ with $Y \in H$.
(d) Show that the group G acts discretely on $\mathbb{R}^2$.

Exercise 48.9. Let $n \in \mathbb{N}$ and let $A \in \mathrm{M}(n \times n, \mathbb{Z})$ be a matrix with non-zero determinant. Show that the map

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ [v] & \mapsto & [A \cdot v] \end{array}$$

is a covering map of degree $|\det(A)|$.
Remark. This can be viewed as a generalization of Exercise 19.14.

Exercise 48.10. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces.

(a) Let f be a loop in (B, b_0). We denote by $\widetilde{f}$ the lift of f to the starting point x_0. Show that if $[f]$ lies in $p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0)$, then $\widetilde{f}$ is a loop in (X, x_0).

(b) Now we suppose that X is simply connected. Let f and g loops in (B, b_0) and let $\widetilde{f}$ and $\widetilde{g}$ be the lifts of f and g to the starting point x_0. Show that if the endpoints of $\widetilde{f}$ and $\widetilde{g}$ agree, then f and g are path-homotopic loops.

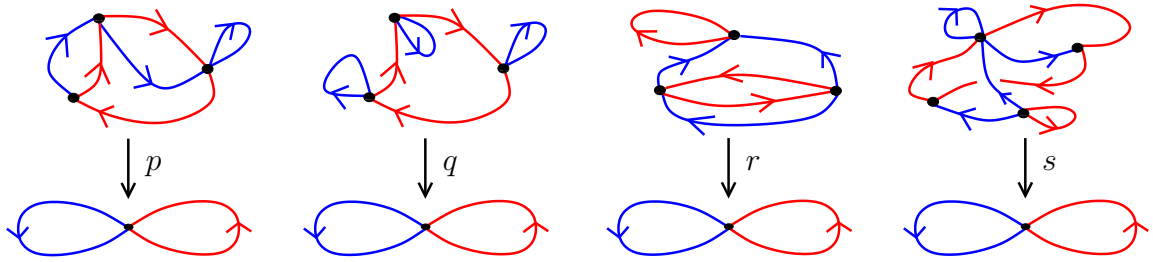
(c) Show that if X is path-connected, then $[X : B] = [\pi_1(B, b_0) : p_*(\pi_1(X, x_0))]$.

Exercise 48.11. Show that there is no covering map from the sphere S^2 to the torus $S^1 \times S^1$.
Hint. Use Lemma 48.15.

Exercise 48.12. We consider the pointed topological space (B, b_0) and we consider the loops $\alpha, \beta\colon [0, 1] \to B$ shown in the figure below.

(a) Show that there exists a covering $p\colon (X, x_0) \to (B, b_0)$ of pointed topological spaces such that the loop $\alpha * \beta * \overline{\alpha} * \overline{\beta}$ does not lift to a loop in (X, x_0).

(b) Use Lemma 48.15 (1) to show that $\pi_1(B, b_0)$ is non-abelian.



Exercise 48.13.

(a) Does there exist a covering map $p\colon K \to T$ from the Klein bottle to the 2-dimensional torus?

(b) Let X be a topological space and let $b \in \pi_1(X, x_0)$. Does there necessarily exist a map $f\colon (S^1, 1) \to (X, x_0)$ with $b \in f_*(\pi_1(S^1, 1))$?

(c) Let X be a topological space and let $b, c \in \pi_1(X, x_0)$. Does there necessarily exist a map $f\colon (S^1 \times S^1, (1, 1)) \to (X, x_0)$ with $b, c \in f_*(\pi_1(S^1 \times S^1, (1, 1)))$?

Exercise 48.14. Which of the maps between topological graphs that are shown in the figure below are covering maps?

Exercise 48.15.

(a) Use the Fundamental Group-via-Actions Theorem 48.16 to show that the fundamental group of the pseudocircle, i.e. of the topological space $X = \{A, B, C, D\}$ from page 141, is isomorphic to $\mathbb{Z}$.

(b) Let $f\colon S^1 \to X$ be the map that we introduced on page 141. Show that the induced map $f_*\colon \pi_1(S^1, 1) \to \pi_1(X, A)$ is an isomorphism.

Exercise 48.16. Let $n \in \mathbb{N}$. We consider the map $f\colon S^1 \to S^1$ that is given by $z \mapsto z^n$. Show that the induced map on $\pi_1(S^1, 1)$ is given by multiplication by n.

Exercise 48.17. Let A and B be topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the maps

$$\begin{array}{rcl} f\colon A & \to & A \times B \\ a & \mapsto & (a, b_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon B & \to & A \times B \\ b & \mapsto & (a_0, b) \end{array}$$

and the map

$$\begin{array}{rcl} \Phi\colon \pi_1(A, a_0) \times \pi_1(B, b_0) & \to & \pi_1(A \times B, (a_0, b_0)) \\ (x, y) & \to & f_*(x) \cdot g_*(y) \end{array}$$

(a) Show that Φ is a monomorphism, i.e. that it is injective.
Hint. Consider the maps

$$\begin{array}{rcl} p\colon A \times B & \to & A \\ (a, b) & \mapsto & a \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon A \times B & \to & B \\ (a, b) & \mapsto & b. \end{array}$$

(b) Show that Φ is an epimorphism, i.e. that it is surjective.
Hint. Let $h(t) = (\alpha(t), \beta(t))$ be a loop in $(A \times B, (a_0, b_0))$. Consider the map

$$\begin{array}{rcl} \Psi\colon [0,1] \times [0,1] & \to & A \times B \\ (s, t) & \mapsto & (\alpha(s), \beta(t)). \end{array}$$

Hint. You might want to use ideas similar to the proof that the map Φ is a homomorphism.

Exercise 48.18. Let $A \in \mathrm{GL}(n, \mathbb{Z})$ be a matrix. In the Maps-on-Torus Lemma 19.37 we saw that the map

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ v & \mapsto & Av \end{array}$$

is a homeomorphism. We identify $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0)$ with $\mathbb{Z}^n$ as in the Fundamental Group-via-Actions Theorem 48.16. Show that the diagram

$$\begin{array}{ccc} \pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) & \xrightarrow{f(A)_*} & \pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle =} \\ \mathbb{Z}^n & \xrightarrow{v \mapsto Av} & \mathbb{Z}^n \end{array}$$

commutes.

Exercise 48.19. Let (X, d) be a metric space and let $p\colon \widetilde{X} \to X$ be a covering. Given $x, y \in \widetilde{X}$ we define

$$\widetilde{d}(x, y) := \inf \left\{ \sum_{i=0}^{n-1} d(w_i, w_{i+1}) \;\middle|\; \begin{array}{c} \text{with } w_0, \ldots, w_n \in X,\ p(w_0) = x,\ p(w_n) = y \text{ and such} \\ \text{that for each } i \in \{0, \ldots, n-1\} \text{ there exists a uniformly} \\ \text{covered open subset that contains } w_i \text{ and } w_{i+1} \end{array} \right\}.$$

(a) Show that $\widetilde{d}$ defines on $\widetilde{X}$ and that the corresponding topology equals the topology of $\widetilde{X}$.
(b) Show that $p\colon \widetilde{X} \to X$ is a local isometry.

Remark Recall that a topological space X is called *metrizable* if there exists a metric d on X such that the given topology agrees with the topology coming from d. The exercise shows in particular that every covering of a metrizable topological space is again metrizable.

Exercise 48.20.

(a) Consider the following maps:

$$\begin{array}{ccc} & & (S^1,1) \\ & \overset{???\ \text{lift}\ \widetilde{f}\ ???}{\nearrow} & \Big\downarrow{\scriptstyle p\ z\mapsto z^2} \\ (S^1,1) & \xrightarrow[f]{z\mapsto z} & (S^1,1). \end{array}$$

Show that the map f does not lift to a map $\widetilde{f}$.

(b) Let $p\colon \widetilde{M} \to M$ be a finite covering and let $f\colon M \to M$ be map. Does there necessarily exist a map $\widetilde{f}\colon \widetilde{M} \to \widetilde{M}$ that makes the following diagram commute:

$$\begin{array}{ccc} \widetilde{M} & \overset{\widetilde{f}}{\dashrightarrow} & \widetilde{M} \\ {\scriptstyle p}\big\downarrow & & \big\downarrow{\scriptstyle p} \\ M & \xrightarrow{\quad f \quad} & M\,? \end{array}$$

Exercise 48.21. Let $p\colon \widetilde{X} \to X$ be a 2-fold covering of a topological space X.

(a) Show that the map

$$\begin{array}{rcl} \Xi\colon \widetilde{X} & \to & \widetilde{X} \\ x & \mapsto & \text{the unique element in } p^{-1}(p(\{x\})) \setminus \{x\} \end{array}$$

is continuous.

(b) Let A be a topological space and let $f\colon A \to X$ be a map. Show that if $\widetilde{f}\colon A \to \widetilde{X}$ is a lift of f, then $\Xi \circ \widetilde{f}$ is the unique other lift of f.

Exercise 48.22. Let $p\colon \widetilde{X} \to X$ be a covering of a connected space X. Show that for each component Y of $\widetilde{X}$ the map $p\colon Y \to X$ is also a covering.

Exercise 48.23. Let X be a topological space and let G be a group that acts continuously, properly and freely on X.

(a) Show that the natural projection $X \to X/G$ is a local homeomorphism.

(b) We denote by $\sim$ the equivalence relation on the topological space $X \times [0,1]$ that is generated by $(x,t) \sim (g \cdot x, t)$ for $g \in G$ and $(x,t) \in X \times [0,1]$. Show that the map

$$\begin{array}{rcl} (X \times [0,1])/\sim & \to & X/G \times [0,1] \\ [(x,t)] & \mapsto & ([x],t) \end{array}$$

is a homeomorphism.

Remark. This is a special case of the Product-Quotient Mixing Lemma 13.6, which relies on the tricky Whitehead Quotient Theorem 13.4. But in our setting, using (a), one can give an elementary proof.

(c) Suppose that $F\colon X \times [0,1] \to X$ is a homotopy that is G-equivariant in the sense that for any $(x,t) \in X \times [0,1]$ and any $g \in G$ we have $F(g \cdot x, t) = g \cdot F(x,t)$. Show that the map

$$\begin{array}{rcl} X/G \times [0,1] & \to & X/G \\ ([x],t) & \mapsto & [F(x,t)] \end{array}$$

is continuous.

Remark. This is a special case of the Homotopy Quotient Theorem 14.7. But in our setting one can deduce it from (b).

Exercise 48.24. We denote by $p\colon \mathbb{R} \to S^1$ the covering map that is given by $t \mapsto \exp(2\pi \mathrm{i} t)$. Let $\epsilon \in \{-1, 1\}$ We say that a map $f\colon \mathbb{R} \to \mathbb{R}$ is ϵ-equivariant if for any $t \in \mathbb{R}$ and $n \in \mathbb{Z}$ we have $f(n + t) = \epsilon \cdot n + f(t)$.

(a) Show that any self-homeomorphism of S^1 lifts to a self-homeomorphism of $\mathbb{R}$ that is ϵ-equivariant for some $\epsilon \in \{-1, 1\}$.

(b) Show that any self-homeomorphism of $\mathbb{R}$ is either monotonously increasing or monotonously decreasing.

(c) Let $g\colon \mathbb{R} \to \mathbb{R}$ be an ϵ-equivariant self-homeomorphism. Show that there exists an isotopy
$$G\colon \mathbb{R} \times [0, 1] \to \mathbb{R}$$
from g to the map that is given by $x \mapsto \epsilon \cdot gx$ and such that each G_t is ϵ-equivariant.

(d) Show that any self-homeomorphism of S^1 is isotopic to the map $f(z) = z$ or to the map $g(z) = \overline{z}$.

Hint. Use Exercise 48.23.

Remark. This gives a new proof of Exercise 14.7 (b).

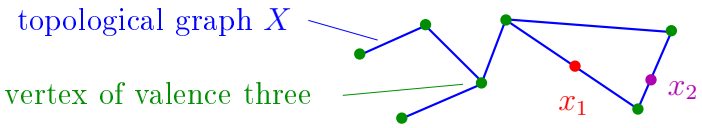
Exercise 48.25. Let Y be a topological space and let $q\colon \widetilde{Y} \to Y$ be a covering. Furthermore let X be a topological space and let $f\colon X \to Y$ be a map. We define the pullback
$$f^*\widetilde{Y} := \{(x, \widetilde{y}) \in X \times \widetilde{Y} \mid f(x) = q(\widetilde{y})\}.$$
We equip $X \times \widetilde{Y}$ with the product topology and we equip $f^*\widetilde{Y}$ with the subspace topology. Finally we consider the maps
$$\begin{array}{rcl} p\colon f^*\widetilde{Y} & \to & X \\ (x, \widetilde{y}) & \mapsto & x \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \widetilde{f}\colon f^*\widetilde{Y} & \to & \widetilde{Y} \\ (x, \widetilde{y}) & \mapsto & \widetilde{y} \end{array}$$

(a) Show that $p\colon f^*\widetilde{Y} \to X$ is a covering with $[f^*\widetilde{Y} : X] = [\widetilde{Y} : Y]$.

Remark. We refer to $p\colon f^*\widetilde{Y} \to X$ as the *pullback* of the covering $q\colon \widetilde{Y} \to Y$.

(b) Recall that a map between topological spaces is *proper* if the preimage of each compact set is open. Show that if $f\colon X \to Y$ is proper, then $\widetilde{f}\colon f^*\widetilde{Y} \to \widetilde{Y}$ is also proper.

Exercise 48.26.



(a) Give an example of a map $f\colon S^1 \times S^1 \to \mathbb{R}^2$ such that there is no $(x, y) \in S^1 \times S^1$ with $f(-x, -y) = f(x, y)$.

(b) Show that given any map $f\colon S^1 \times S^1 \to \mathbb{R}$ there exists an $(x, y) \in S^1 \times S^1$ with $f(-x, -y) = f(x, y)$.

Exercise 48.27. Let $k \in \mathbb{N}$ and let X be a topological manifold. We refer to
$$\mathrm{Conf}_k(X) := \{(x_1, \ldots, x_k) \in X^k \mid \text{for all } i \neq j \text{ we have } x_i \neq x_j\}$$
as the *configuration space of k points in X*. Let $X \subset \mathbb{R}^2$ be a connected topological graph that has at least one vertex of valence three. Show that $\pi_1(\mathrm{Conf}_2(X))$ admits an

epimorphism onto $\mathbb{Z}$.
Hint. Consider the map

$$\begin{array}{rcl} \mathrm{Conf}_2(X) & \to & S^1 \\ (x_1, x_2) & \mapsto & \frac{x_2 - x_1}{\|x_2 - x_1\|}. \end{array}$$

49. Coverings of smooth and topological manifolds

49.1. **Fundamental groups of topological manifolds.** Our only goal in this section is to prove a proposition, which will help us with dealing with a technical issue in the following section. But the proposition is also interesting in its own right and it provides a good way to practice what we learned in the last chapters.

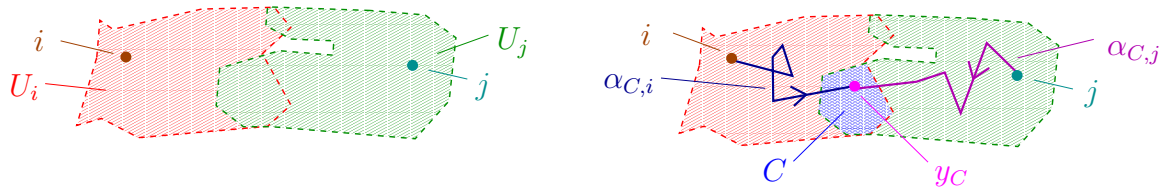
Proposition 49.1. (Countable Fundamental Group Proposition)

(1) Let X be a topological space and let $x_0 \in X$. If X is second-countable and locally simply connected, then $\pi_1(X, x_0)$ is countable.
(2) If X is a topological manifold and if $x_0 \in X$, then $\pi_1(X, x_0)$ is countable.

Remark.

(1) In Proposition 96.7 and 104.15 we will give an alternative proof of the Countable Fundamental Group Proposition 49.1 for smooth respectively topological manifolds.
(2) In Propositions 96.6, 104.14 and on page 2997 we will see that fundamental groups of compact topological manifolds are in fact "finitely generated".

Proof. The second statement follows almost immediately from the first statement. Indeed, first note that topological manifolds are by definition second-countable. Furthermore note that in the Topological Manifolds-Local Properties Lemma 18.8 we showed that an n-dimensional topological manifold is locally homeomorphic to non-empty convex subsets of $\mathbb{R}^n$. It follows immediately from the Convex Homotopy Lemma 14.1, or from the discussion on page 1055, that non-empty convex subsets of $\mathbb{R}^n$ are simply connected. This shows that topological manifolds are locally simply connected.



Now we turn to the proof of the first statement. Thus let X be a topological space that is second-countable and locally simply connected. Furthermore let $x_0 \in X$. Since X is locally simply connected we know that for each $x \in X$ there exists an open neighborhood $U_x \subset X$ of x that is simply connected. Since X is second-countable we know by the Countable Covering Lemma 9.2 that there exists a countable subset $I \subset X$ such that $X = \bigcup_{i \in I} U_i$. We pick $i_0 \in I$ in the path-component of x_0. By the Change-of-Base Point Proposition 47.10 it suffices to show that $\pi_1(X, i_0)$ is countable.

Claim 1. For each $i, j \in I$ the intersection $U_i \cap U_j$ has only countably many path-components, i.e. $\pi_0(U_i \cap U_j)$ is countable.

Proof. Let $\{W_k\}_{k \in K}$ be the path-components of $U_i \cap U_j$. For each $k \in K$ we pick a point z_k. Since U_i and U_j are open we know that $U_i \cap U_j$ is also open. Since X is locally simply connected we see that there exists a simply connected neighborhood C_k of z_k with $C_k \subset U_i \cap U_j$. Recall that "simply connected" means in particular that C_k is path-connected. Therefore it follows from the Path-Component Lemma 2.31 that $C_k \subset W_k$. Thus we see that the open sets C_k, $k \in K$ are disjoint. Now we obtain from our hypothesis that X is second-countable, together with say the Countable Covering Lemma 9.2, that K is countable. ⊞

Let $i, j \in I$. Given any $C \in \pi_0(U_i \cap U_j)$ we pick a point $y_C \in C_{i,j}$. Since U_i and U_j are in particular path-connected we can pick a path $\alpha_{C,i}$ from i to y_C and we can pick a path $\alpha_{C,j}$

from j to y_C. Note that it follows from Claim 1 together with the Countability Lemma 0.8 that the set $\bigcup_{i\in I}\bigcup_{j\in J}\pi_0(U_i\cap U_j)$ is countable. Thus it remains to prove the following claim.

Claim 2. Every loop in i_0 is path-homotopic to a composition of the paths $\alpha_{C,i}$ and their inverses.

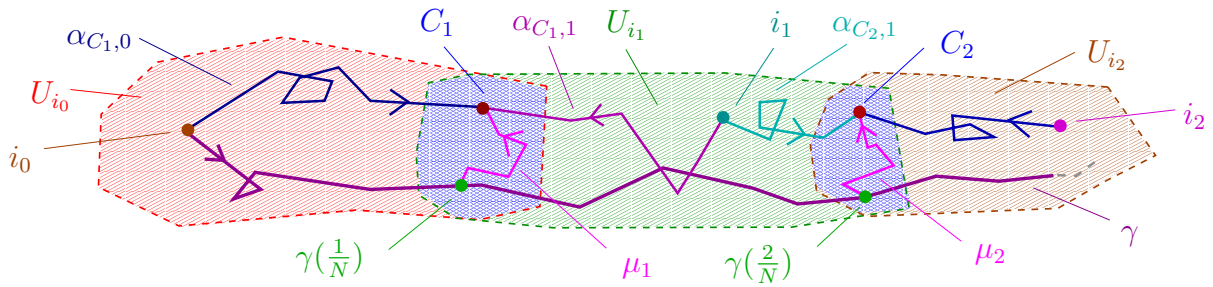
Proof. Let $\gamma\colon[0,1]\to X$ be a loop in i_0. We start out with a few preparations:

- Since the sets $\{U_i\}_{i\in I}$ form an open cover and since $[0,1]$ is compact we obtain easily from the Lebesgue Corollary 6.6 that there exists an $N\in\mathbb{N}$ and $i_1,\dots,i_{N-1}\in I$ such that for each $k\in\{0,\dots,N-1\}$ we have $\gamma([\frac{k}{N},\frac{k+1}{N}])\subset U_{i_k}$.
- Given $k\in\{0,\dots,N-1\}$ we define γ_k to be the restriction of γ to the interval $[\frac{k}{N},\frac{k+1}{N}]$.
- For $k=1,\dots,N-1$ we have $\gamma(\frac{k}{N})\in U_{i_{k-1}}\cap U_{i_k}$. We denote by C_k the path-component of $U_{i_{k-1}}\cap U_{i_k}$ that contains $\gamma(\frac{k}{N})$. Since C_k is path-connected there exists a path $\mu_k\colon[0,1]\to C_k$ from $\gamma(\frac{k}{N})$ to y_{C_k}.

Next we reuse some notation that we had introduced earlier on.

- Given a path $\delta\colon[a,b]\to X$ we denote, as on page 1051, by $[\delta]$ the path-homotopy class of δ.
- Given two paths $\delta\colon[a,b]\to X$ and $\epsilon\colon[c,d]\to X$ with $\delta(b)=\epsilon(c)$ we denote by $\delta*\epsilon\colon[0,1]\to X$ the concatenation as defined on page 1052.
- Given a path $\delta\colon[0,1]\to X$ we denote by $\overline{\delta}\colon[0,1]\to X$ the inverse path that is given by $\overline{\delta}(t)=\delta(1-t)$.

Now we can provide the actual proof of the claim. By constantly using the Path-Homotopy Concatenation Proposition 47.5 and Lemmas 47.4 we obtain that



$$\begin{aligned}
[\gamma] &= [\gamma_0 * \gamma_1 * \ldots * \gamma_{N-1}] \\
&= [\underbrace{\gamma_0 * \mu_1}_{\substack{\text{same endpoints}\\ \text{as } \alpha_{C_1,0}}} * \underbrace{\overline{\mu_1} * \gamma_1 * \mu_2}_{\substack{\text{same endpoints}\\ \text{as } \overline{\alpha_{C_1,1}} * \alpha_{C_2,1}}} * \overline{\mu_2} * \ldots * \mu_{N-1} * \underbrace{\overline{\mu_{N-1}} * \gamma_{N-1}}_{\substack{\text{same endpoints}\\ \text{as } \overline{\alpha_{C_{N-1},N}}}}] \\
&\overset{\uparrow}{=} [\alpha_{C_1,0} * \overline{\alpha_{C_1,1}} * \alpha_{C_1,1} * \ldots * \overline{\alpha_{C_{N-1},N}}]
\end{aligned}$$

here we use Lemma 47.12 and that the U_{i_k} are simply connected

We have thus proved the desired statement. ∎

49.2. **Manifold structures on coverings of manifolds.** We recall the following definition from page 1067.

Definition. Let $p\colon X\to B$ be a map between two topological spaces. We say the map $p\colon X\to B$ is a covering, if it is surjective and if for every $b\in B$ there exists an open neighborhood U of b which is uniformly covered, i.e. $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i\in I}$ with the property that the restriction of p to each subset V_i is a homeomorphism.

In the context of smooth and complex manifolds it is appropriate to introduce the following variation.

Definition.

(1) Let $p\colon X \to B$ be a map between smooth manifolds. We say the map $p\colon X \to B$ is a covering of smooth manifolds, if it is surjective and if for every $b \in B$ there exists an open neighborhood U of b such that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i\in I}$ with the property, that the restriction of p to each subset V_i is a diffeomorphism.

(2) We have the analogous definition of a covering between complex manifolds, we just need to replace "diffeomorphism" by "biholomorphism".

Remark. Note that a covering map between smooth manifolds is in particular a local diffeomorphism, which implies by the Smooth Pasting Proposition 19.23 that it is smooth.

Example. We consider the smooth manifold $M = \mathbb{R}$ and the map

$$\begin{array}{ccc} \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & x^3. \end{array}$$

This map is a homeomorphism, in particular it is a 1-fold covering between topological spaces. On the other hand this map is not a (local) diffeomorphism, hence it is not a covering between smooth manifolds.

Proposition 49.2. (Manifold Covering Proposition) Let X be an n-dimensional topological manifold and let $p\colon \widetilde{X} \to X$ be a covering.

(0) If X and $\widetilde{X}$ are connected, then $p\colon \widetilde{X} \to X$ is a countable covering.[509]

Now suppose that $p\colon \widetilde{X} \to X$ is a countable covering.

(1) The covering space $\widetilde{X}$ is also an n-dimensional topological manifold.

(2) (a) If X admits a smooth atlas, then $\widetilde{X}$ admits a smooth atlas such that $p\colon \widetilde{X} \to X$ is a covering of smooth manifolds.

(b) If X is equipped with a smooth structure[510] then $\widetilde{X}$ admits a *unique* smooth structure such that $p\colon \widetilde{X} \to X$ is a covering of smooth manifolds.

(3) (a) Regardless of whether we work with smooth or topological manifolds we have the equality $\partial\widetilde{X} = p^{-1}(\partial X)$.

(b) If $p\colon \widetilde{X} \to X$ is a finite covering and if X is a *closed* smooth or topological manifold, then so is $\widetilde{X}$.

(4) If X is an oriented smooth manifold, then $\widetilde{X}$ admits a unique orientation such that $p\colon \widetilde{X} \to X$ is orientation-preserving.
(5) If X is equipped with a complex structure, then $\widetilde{X}$ admits a unique complex structure such that $p\colon \widetilde{X} \to X$ is a covering of complex manifolds.

Convention. If M is a smooth manifold, i.e. if M is a topological manifold equipped with a smooth structure, and if we are given a covering $p\colon \widetilde{M} \to M$, then usually we equip $\widetilde{M}$ with the unique smooth structure given by the Manifold Covering Proposition 49.2 (2b). The same convention also applies to coverings of oriented smooth manifolds and to coverings of complex manifolds.

In the proof of the Manifold Covering Proposition 49.2 we will need the following technical lemma.

Auxiliary Lemma 49.3. Let $p\colon \widetilde{X} \to X$ be a countable covering of a topological space X. If X is second-countable, then $\widetilde{X}$ is also second-countable.

Proof of Lemma 49.3. Let $p\colon \widetilde{X} \to X$ be a countable covering of a topological space X. Recall that we say $U \subset X$ is uniformly covered, if $p^{-1}(U)$ is the union of disjoint open subsets $\{\widetilde{U}_i\}_{i\in I}$ with the property that the restriction of p to each subset $\widetilde{U}_i$ is a homeomorphism. If U is uniformly covered, then it follows from the remark on page 1067 that every open subset of U is also uniformly covered.

Let $\mathcal{B}$ be a countable basis for the topology of X. We denote by $\mathcal{U} = \{U_j\}_{j\in J}$ the family of all open subsets of X that are uniformly covered. Since p is a covering we have $\bigcup_{j\in J} U_j = X$. It follows from Lemma 1.30 that

$$\mathcal{B}' := \{B \in \mathcal{B} \mid \text{ there exists a } j \in J \text{ with } B \subset U_j\}$$

is also a basis for the topology of X.

Now let $B \in \mathcal{B}'$. Since open subsets of uniformly covered subsets are uniformly covered we know that $p^{-1}(B)$ is the union of disjoint open sets B_i, $i \in I_B$ such that the restriction of p to each B_i is a homeomorphism. Since p is a countable covering the index set I_B is countable.

Claim. $$\widetilde{\mathcal{B}} := \{B_i \mid B \in \mathcal{B}' \text{ and } i \in I_B\}$$ is a basis for the topology of $\widetilde{X}$.

Proof. It is straightforward to see that $\widetilde{\mathcal{B}}$ has the basis property. Every set in $\widetilde{\mathcal{B}}$ is of course open in $\widetilde{X}$. By Lemma 1.29 it suffices to show that given any open set W of $\widetilde{X}$ and any point $x \in W$ there exists a set B_i in $\widetilde{\mathcal{B}}$ with $x \in B \subset W$. So let $x \in W$. Since $\mathcal{B}'$ is a basis for the topology of X there exists a $B \in \mathcal{B}'$ with $p(x) \in B \subset p(W)$. But then there exists an $i \in I_B$ with $x \in B_i \subset W$. ⊞

Since $\mathcal{B}'$ is countable and since each I_B is countable we know by the Countability Lemma 0.8 that $\widetilde{\mathcal{B}}$ consists of countably many open sets. This shows that $\widetilde{X}$ is second-countable. ■

[509] Recall that a covering $p\colon \widetilde{X} \to X$ of a connected space is called *countable* if the degree, i.e. the cardinality of the preimage of a point in X, is countable.
[510] We refer to page 543 for the definition of a smooth structure on a smooth manifold.

Proof of the Manifold Covering Proposition 49.2. Let X be an n-dimensional topological manifold and let $p\colon \widetilde{X} \to X$ be a covering.

(0) Suppose that X and $\widetilde{X}$ are path-connected. If X is the empty set there is nothing to show. If X is non-empty, we pick $x_0 \in X$. Furthermore we pick $\widetilde{x}_0 \in \widetilde{X}$ with $p(\widetilde{x}_0) = x_0$. By the Countable Fundamental Group Proposition 49.1 we know that $\pi_1(X, x_0)$ is countable. By Lemma 48.15 we know that $[\widetilde{X} : X] = |\pi_1(X, x_0) : p_*(\pi_1(\widetilde{X}, \widetilde{x}_0))|$. It follows from the fact that $\pi_1(X, x_0)$ is countable and the Countability Lemma 0.8 that $[\widetilde{X} : X]$ is countable.

Now we assume that $p\colon \widetilde{X} \to X$ is a countable covering.

(1) First we note that it follows from the hypothesis that X is a topological manifold that X is Hausdorff. It follows from Lemma 48.3 (3) that $\widetilde{X}$ is also Hausdorff. Next note that it follows from our hypothesis that X is a topological manifold and that p is a countable covering, together with Lemma 49.3, that $\widetilde{X}$ is second-countable.

Since $p\colon \widetilde{X} \to X$ is a covering there exists a family of open subsets $\{U_i\}_{i\in I}$ of X such that each U_i is uniformly covered. Furthermore, since X is an n-dimensional topological manifold there exists an atlas $\{\Phi_j\colon V_j \to W_j\}_{j\in J}$ for X. After possibly replacing each V_j by the family $\{V_j \cap U_i\}_{i\in I}$ we can without loss of generality assume that each V_j is uniformly covered. Thus for each j the preimage $p^{-1}(V_j)$ is the union of disjoint open subsets $\{\widetilde{V}_{ji}\}_{i\in I_j}$ with the property, that the restriction of p to each subset $\widetilde{V}_{ji}$ is a homeomorphism. It is clear that $\{\Phi_j \circ p\colon \widetilde{V}_{ji} \to W_j \mid j \in J \text{ and } i \in I_j\}$ is an n-dimensional atlas for $\widetilde{X}$.

(2) (a) The transition maps of the atlas from (1) are precisely given by restrictions to open subsets of the transition maps of the atlas $\{\Phi_j\colon V_j \to W_j\}_{j\in J}$ for X. Thus if we start out with a smooth atlas for X, then the atlas we just constructed for $\widetilde{X}$ is also smooth.

Since $p\colon \widetilde{X} \to X$ is a covering we know that each $x \in X$ admits an open neighborhood U such that $p^{-1}(U)$ is the union of a family $\{V_i\}_{i\in I}$ of disjoint open subsets such that each $p\colon V_i \to U$ is a homeomorphism. By the definition of the smooth structure on $\widetilde{X}$ these maps are now diffeomorphisms. We have thus shown that $p\colon \widetilde{X} \to X$ is a covering of smooth manifolds.

(b) This statement follows immediately from (a), together with the rather straightforward Exercise 19.33.

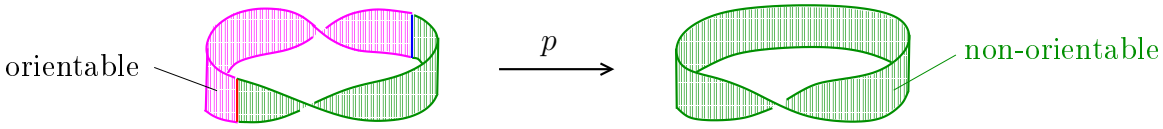
(3) (a) Let X be a topological manifold. Since $p\colon \widetilde{X} \to X$ is a local homeomorphism we obtain easily from Lemma 18.5 that $\partial\widetilde{X} = p^{-1}(\partial X)$. If X is in fact a smooth manifold, then the statement follows from the fact that now $p\colon \widetilde{X} \to X$ is a local diffeomorphism together with Lemma 19.27.

(b) This statement follows from (a) together with Lemma 48.3.

(4) This statement follows immediately from the fact that p is a local diffeomorphism together with the Basics-of-Orientations Lemma 25.13 (6).

(5) The proof of this statement is almost identical to the proof of (2). We leave it to the reader to fill in the details. ∎

49.3. **The orientation covering of a non-orientable smooth manifold.** We saw that many of our examples of non-orientable smooth manifolds admit a 2-fold covering such that the covering space is an orientable smooth manifold:



Examples.

(1) By the discussion on page 1069 the projection $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/\{\pm 1\}$ is a 2-fold covering. This shows that the real projective plane is covered by the sphere.

(2) On page 1070 we had considered the map

$$\begin{array}{rcl} p\colon \overbrace{(\mathbb{R}\times[-1,1])/(x,y)\sim(x+1,y)}^{\text{annulus}} & \to & \overbrace{(\mathbb{R}\times[-1,1])/(x,y)\sim(x+\frac{1}{2},1-y)}^{\text{Möbius band}} \\ [(x,y)] & \to & [(x,y)] \end{array}$$

and we remarked that this is a 2-fold covering. Thus the non-orientable Möbius band admits a 2-fold covering such that the covering space is orientable.

(3) Almost the same map as in (2) also shows that there exists a 2-fold covering map from the torus to the Klein bottle.

In this section we will see that every non-orientable smooth manifold admits a 2-fold covering such that the covering space is orientable. Furthermore we will see that this 2-fold covering is in a suitable sense unique.
First let us introduce and recall some notation which we will use throughout this section.

Notation.

(1) Given an orientation $\mathcal{O}$ for a real vector space we denote by $-\mathcal{O}$ the unique other orientation.

(2) Given an isomorphism $\varphi\colon V \to W$ between vector spaces and given an orientation $\mathcal{O}$ on V we denote by $\varphi(\mathcal{O})$ the corresponding orientation on W.

Proposition 49.4. Let M be a smooth manifold. We consider the set

$$\widetilde{M} \;=\; \{(Q,\mathcal{O}) \mid Q\in M \text{ and } \mathcal{O} \text{ is an orientation of } \mathrm{T}_Q M\}$$

together with the map

$$\begin{array}{rcl} p = p_M\colon \widetilde{M} & \to & M \\ (Q,\mathcal{O}) & \mapsto & Q. \end{array}$$

(1) There exists a unique topology on $\widetilde{M}$ such that $p_M\colon \widetilde{M} \to M$ is a 2-fold covering.

(2) There exists a unique smooth structure on the topological space $\widetilde{M}$ such that the projection $p_M\colon \widetilde{M} \to M$ is a covering of smooth manifolds.

(3) Let $\widetilde{x} = (x,\mathcal{O}) \in \widetilde{M}$. By (2) the map $p\colon \widetilde{M} \to M$ is a local diffeomorphism, which implies that $\mathrm{D}p_{\widetilde{x}}\colon \mathrm{T}_{\widetilde{x}}\widetilde{M} \to \mathrm{T}_x M$ is an isomorphism. Now we equip $\mathrm{T}_{\widetilde{x}}\widetilde{M}$ with the orientation $(\mathrm{D}p_{\widetilde{x}})^{-1}(\mathcal{O})$. These orientations of the tangent spaces of $\widetilde{M}$ define an orientation of the smooth manifold $\widetilde{M}$.

Definition. Let M be a smooth manifold. The covering $p_M\colon \widetilde{M} \to M$ from Proposition 49.4 is called the orientation covering of M. We always equip $\widetilde{M}$ with the topology, smooth structure and orientation from Proposition 49.4.

Remark. In the Orientation Covering-Proposition 105.15 we will prove an analogue of Proposition 49.4 for topological manifolds.

Proof. Let M be an n-dimensional smooth manifold.

(1) Let $\Phi\colon U \to V$ be a chart of the smooth atlas of M and let $\epsilon \in \{-,+\}$. We introduce the following notation:
- We denote by $i\colon U \to M$ the inclusion map.
- For $x \in V \subset \mathbb{R}^n$ we denote by $\mathcal{O}_{V,x}$ the standard orientation of $\mathrm{T}_x V$ that we introduced on page 677.

We set
$$B_\epsilon(\Phi) \;:=\; \{(Q, \underbrace{\epsilon \cdot (\mathrm{D}i_Q \circ (\mathrm{D}\Phi_Q)^{-1})(\mathcal{O}_{V,\Phi(Q)})}_{\text{orientation of } \mathrm{T}_Q M}) \mid Q \in U\} \;\subset\; \widetilde{M}.$$

It is straightforward to show that the collection of these sets $B_\pm(\Phi)$ satisfies the basis properties (B1) and (B2) from page 132. Now we endow $\widetilde{M}$ with the topology generated by the sets $B_\pm(\Phi)$.

Claim 1. The projection $p\colon \widetilde{M} \to M$ is continuous.

Proof. Note that for each chart $\Phi\colon U \to V$ of M we have $p^{-1}(U) = B_-(\Phi) \cup B_+(\Phi)$. This shows that $p^{-1}(U)$ is in fact an open subset of $\widetilde{M}$. Next note that it follows from the Basis Characterization Lemma 1.32 that the domains of the charts for M have the basis property for the topological space M. Combining these two observations with the Subbasis-Continuity Proposition 2.9 we see that p is indeed continuous. ⊞

Claim 2. The projection $p\colon \widetilde{M} \to M$ is a 2-fold covering.

Proof. Let $Q \in M$. We pick a chart $\Phi\colon U \to V$ around Q such that U is connected. Note that $p^{-1}(U) = B_-(\Phi) \cup B_+(\Phi)$. It follows from the Basics-of-Orientations Lemma 25.13 (1), applied to the connected smooth manifold U, that $B_-(\Phi)$ and $B_+(\Phi)$ are disjoint. Evidently the maps $p\colon B_\pm(\Phi) \to U$ are bijections.

Let $\epsilon \in \{-,+\}$. Using Lemma 2.11 one sees easily that the map $p\colon B_\epsilon(\Phi) \to U$ is open. We already know that the map $p\colon B_\epsilon(\Phi) \to U$ is continuous. Thus it follows from the Open -Injective Map Lemma 2.16 that the map $p\colon B_\epsilon(\Phi) \to U$ is a homeomorphism.

In summary we have shown that U is uniformly covered by the two open sets $B_\pm(\Phi)$. This implies that p is a 2-fold covering. ⊞

Finally note that the uniqueness of the topological structure on $\widetilde{M}$ with the desired properties is an immediate consequence of the fairly elementary Exercise 2.3.

(2) This statement is an immediate consequence of (1) and the Manifold Covering Proposition 49.2 (2).

(3) It follows immediately from the definition of the smooth structure on $\widetilde{M}$, see the Manifold Covering Proposition 49.2 (2), that a smooth atlas for $\widetilde{M}$ is given by the maps $\Phi \circ p\colon B_\epsilon(\Phi) \to V$, where Φ runs over all smooth charts $\Phi\colon U \to V$ of M with

U connected, and where $\epsilon \in \{-,+\}$. By the Orientations-via-Atlas Lemma 25.8 it suffices to consider the continuity of the orientation with respect to the above atlas. So let $\Phi\colon U \to V$ be a chart of M such that U is connected and let $\epsilon \in \{-,+\}$. We denote by $\Phi_\epsilon = \Phi \circ p\colon B_\pm(\Phi) \to V$ the corresponding chart of $\widetilde{M}$. But then by construction we know that Φ_ϵ is orientation-preserving for all points if $\epsilon = +$ and it is orientation-reversing for all points if $\epsilon = -$. ■

The following proposition summarizes the key properties of the orientation coverings.

Proposition 49.5. (Orientation Covering-Proposition)

(1) Let $f\colon M \to N$ be a local diffeomorphism between smooth manifolds. The map

$$\begin{array}{rcl} \widetilde{f}\colon \widetilde{M} & \to & \widetilde{N} \\ (P, \underset{\uparrow}{\mathcal{O}}) & \mapsto & (f(P), \mathrm{D}f_P(\underset{\uparrow}{\mathcal{O}})). \\ \text{orientation of } \mathrm{T}_P M & & \text{orientation of } \mathrm{T}_{f(P)} N \end{array}$$

is the unique orientation-preserving local diffeomorphism $\widetilde{M} \to \widetilde{N}$ that has the property that the following diagram commutes:[511]

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{\widetilde{f}} & \widetilde{N} \\ {\scriptstyle p_M}\downarrow & & \downarrow{\scriptstyle p_N} \\ M & \xrightarrow{f} & N. \end{array}$$

(2) Let M be a connected smooth manifold.

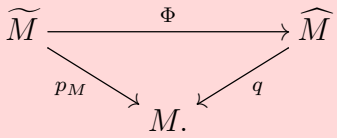
(a) If M is oriented, then there exists a unique orientation-preserving diffeomorphism $\Theta\colon \widetilde{M} \to M \sqcup -M$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow[\cong]{\Theta} & M \sqcup -M \\ & {\scriptstyle p_M}\searrow \quad \swarrow{\scriptstyle q} & \\ & M & \end{array}$$

where q is the obvious map given by the identity on each component of $M \sqcup -M$.

(b) If M is non-orientable, then $\widetilde{M}$ is connected.

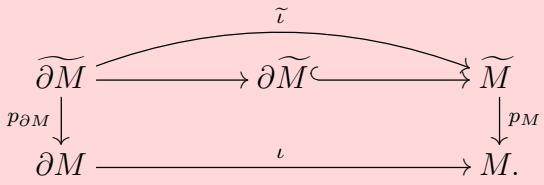
(3) Let M be a smooth manifold. The map



$$\begin{array}{rcl} \Xi_M\colon \widetilde{M} & \to & \widetilde{M} \\ (Q, \mathcal{O}) & \mapsto & (Q, -\mathcal{O}) \end{array}$$

is the unique orientation-reversing self-diffeomorphism $\Xi_M\colon \widetilde{M} \to \widetilde{M}$ which has the property that the following diagram commutes:

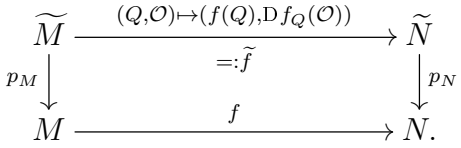
$$\begin{array}{ccc} \widetilde{M} & \xrightarrow[\cong]{\Xi_M} & \widetilde{M} \\ & {\scriptstyle p_M}\searrow \quad \swarrow{\scriptstyle p_M} & \\ & M. & \end{array}$$



Furthermore, given a local diffeomorphism $f\colon M \to N$ we have $\widetilde{f} \circ \Xi_M = \Xi_N \circ \widetilde{f}$.

(4) Let M be a connected non-orientable smooth manifold. Suppose $q\colon \widehat{M} \to M$ is a 2-fold covering of smooth manifolds such that $\widehat{M}$ is a connected orientable smooth manifold. There exists a unique diffeomorphism $\Phi\colon \widetilde{M} \to \widehat{M}$ such that the following diagram commutes:

If $\widehat{M}$ is oriented, then there exists a unique orientation-preserving diffeomorphism $\Phi\colon \widetilde{M} \to \widehat{M}$ that makes the above diagram commute.



(5) Let M be a smooth manifold. We denote by $\iota\colon \partial M \to M$ the inclusion. There exists a unique natural diffeomorphism $\partial\widetilde{M} \to \widetilde{\partial M}$ such that the following diagram commutes:

Remark. In the Orientation Covering-Proposition 105.15 we will prove an analogue of the Orientation Covering-Proposition 49.5 for topological manifolds.

Sketch of proof.

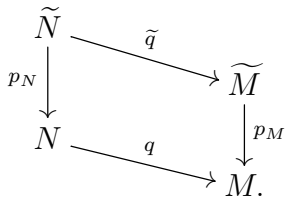
(1) It is clear that the following diagram commutes:

From the fact that p_M, p_N and f are local diffeomorphisms it follows easily that the top map $\widetilde{f}\colon \widetilde{M} \to \widetilde{N}$ is also a local diffeomorphism. It follows immediately from the definitions of the orientations on $\widetilde{M}$ and $\widetilde{N}$ that $\widetilde{f}$ is indeed orientation-preserving. The proof of the fact that $\widetilde{f}$ is the unique map with the stated properties follows easily from Lemma 48.4 (2).

(2) Let M be a connected smooth manifold.

(a) We suppose that M is oriented. One can easily verify that the map

$$\begin{array}{rcl} \Theta\colon \widetilde{M} & \to & M \sqcup -M \\ (P,\mathcal{O}) & \mapsto & \begin{cases} P \in M, & \text{if } \mathcal{O} \text{ is a positive orientation,} \\ P \in -M, & \text{if } \mathcal{O} \text{ is a negative orientation} \end{cases} \end{array}$$



is an orientation-preserving diffeomorphism $\Theta\colon \widetilde{M} \to M \sqcup -M$ that has the desired properties. Uniqueness can once again be deduced from Lemma 48.4 (2).

[511] We leave it to the reader to express this statement in categorical language.

(b) Now we suppose that M is non-orientable. We need to show that $\widetilde{M}$ is connected. If $\widetilde{M}$ was not connected, then $\widetilde{M}$ would consist of at least two components $\{\widetilde{M}_i\}_{i\in I}$. Since M is connected it follows from Exercise 48.22 that the restriction of each $p\colon \widetilde{M} \to M$ to $p_i\colon \widetilde{M}_i \to M$ is also a covering of smooth manifold. Clearly $2 = [\widetilde{M} : M] = \sum_{i\in I}[\widetilde{M}_i : M]$. It follows that $\#I = 2$ and that each $p_i\colon \widetilde{M}_i \to M$ is a covering of degree one, i.e. each p_i is a diffeomorphism. But that is not possible since M was assumed to be non-orientable whereas $\widetilde{M}_i$ is orientable.

(3) It is straightforward to show that Ξ_M is a local diffeomorphism. It is basically clear that it is orientation-preserving. The uniqueness follows easily from Lemma 48.4 (2). Finally, if we are given given a local diffeomorphism $f\colon M \to N$, then it follows immediately from the definitions that we have $\widetilde{f} \circ \Xi_M = \Xi_N \circ \widetilde{f}$.

(4) Let M be a connected non-orientable smooth manifold. Suppose we are given a 2-fold covering $q\colon N \to M$ of smooth manifolds where N is a connected orientable smooth manifold and where q is a local diffeomorphism. Since q is a local diffeomorphism we can consider the corresponding local diffeomorphism $\widetilde{q}\colon \widetilde{N} \to \widetilde{M}$ from (1) which makes the following diagram commute

It follows easily from the fact that q, p_M and p_N are 2-fold coverings of smooth manifolds that $\widetilde{q}\colon \widetilde{N} \to \widetilde{M}$ is also a 2-fold covering of smooth manifolds. From the fact that N is connected and orientable together with (2) we obtain that $\widetilde{N}$ consists of two components $\widetilde{N}_1$ and $\widetilde{N}_2$. As in (2) we see that the restriction of p_N to $\widetilde{N}_1$ and the restriction of $\widetilde{q}$ to $\widetilde{N}_2$ are 1-fold coverings of smooth manifolds. In other words $p_N\colon \widetilde{N}_1 \to N$ is in fact a diffeomorphism. One can now easily verify that $\widetilde{q} \circ (p_N|_{\widetilde{N}_1})^{-1}\colon N \to \widetilde{M}$ has the desired properties.

If N is oriented, then, after possibly composing the diffeomorphism $N \to \widetilde{M}$ with the orientation-reversing diffeomorphism $\Xi\colon \widetilde{M} \to \widetilde{M}$ from (3), we can arrange that the diffeomorphism $N \to \widetilde{M}$ is orientation-preserving. Once again one can deduce from Lemma 48.4 (2) that the orientation-preserving diffeomorphism $\Phi\colon N \to \widetilde{M}$, that commutes with the projections to M, is unique.

(5) We will not make use of this statement. Thus we have no qualms with delegating the proof of this statement to Exercise 49.10. ■

49.4. **The orientation character.** We start out with an elementary lemma in group theory.

Lemma 49.6.

(1) Let π be a group. Any subgroup of index 2 is normal.

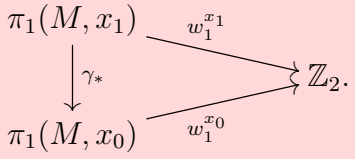
(2) If G is a group with two elements, then there exists a unique isomorphism $G \to \mathbb{Z}_2$.

Proof. We outsource the proof to Exercise 49.1. ■

Convention. Let G be a group with two elements. It follows from Lemma 49.6 (2) that we can safely make the identification $G = \mathbb{Z}_2$.

Proposition 49.7. Let M be a non-orientable connected smooth manifold and let $x_0 \in M$. We denote by $p\colon \widetilde{M} \to M$ the orientation cover. Finally we pick a point $\widetilde{x}_0 \in \widetilde{M}$ with $p(\widetilde{x}_0) = x_0$.

(1) The subgroup $p_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) \subset \pi_1(M, x_0)$ is a normal subgroup of index 2.
(2) There exists a unique isomorphism $\pi_1(M, x_0)/p_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) \to \mathbb{Z}_2$.
(3) The projection



$$w_1^{x_0}\colon \pi_1(M, x_0) \;\to\; \pi_1(M, x_0)/p_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) \;\underset{\uparrow}{=}\; \mathbb{Z}_2$$

(see above convention)

is an epimorphism that does not depend on the choice of $\widetilde{x}_0$.
(4) Let $x_1 \in M$ be some other point and let $\gamma\colon [0,1] \to M$ be a path from x_0 to x_1. We denote by

$$\begin{array}{rcl} \gamma_*\colon \pi_1(M, x_1) & \to & \pi_1(M, x_0) \\ [\varphi] & \mapsto & [\gamma * \varphi * \overline{\gamma}] \end{array}$$

the isomorphism that we introduced in the Change-of-Base Point Proposition 47.10. The following diagram commutes:

Proof. Let M be a non-orientable connected smooth manifold, let $x_0 \in M$ and let $\widetilde{x}_0 \in \widetilde{M}$ with $p(\widetilde{x}_0) = x_0$.

(1) By Proposition 49.4 the orientation covering $p\colon \widetilde{M} \to M$ has degree 2. Furthermore, since M is non-orientable we know by the Orientation Covering-Proposition 49.5 that $\widetilde{M}$ is connected Therefore it follows from Lemma 48.15 that $p_*(\pi_1(\widetilde{M}))$ is an index 2 subgroup of $\pi_1(M)$. By Lemma 49.6 (1) we know that every index 2 subgroup of a group is normal. In particular $p_*(\pi_1(\widetilde{M}))$ is a normal subgroup of $\pi_1(M)$ of index 2.
(2) This statement is an immediate consequence of Lemma 49.6 (2).
(3) By the above it remains to show that the epimorphism $w_1^{x_0}$ does not depend on the choice of $\widetilde{x}_0$. So let $\widehat{x}_0$ be the unique other point in $p^{-1}(x_0)$. By the Orientation Covering-Proposition 49.5 (3) there exists a homeomorphism $\Xi\colon \widetilde{M} \to \widetilde{M}$ with $\Xi(\widetilde{x}_0) = \widehat{x}_0$ and with $p = p \circ \Xi$. We see that

$$\begin{array}{ccccccc} & & \overset{\text{since } p = p\circ\Xi}{\downarrow} & & \overset{\text{functoriality of } \pi_1}{\downarrow} & & \\ p_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) & \overset{}{=} & (p \circ \Xi)_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) & \overset{}{=} & p_*(\Xi_*(\pi_1(\widetilde{M}, \widetilde{x}_0))) & & \\ & & & \underset{\uparrow}{=} & p_*(\pi_1(\widetilde{M}, \Xi(\widetilde{x}_0))) & \underset{\uparrow}{=} & p_*(\pi_1(\widetilde{M}, \widehat{x}_0)). \\ & & & \text{since } \Xi \text{ homeomorphism and since } \pi_1 \text{ is functorial} & & \text{since } \Xi(\widetilde{x}_0) = \widehat{x}_0 & \end{array}$$

(4) Let $\gamma\colon [0,1] \to M$ be a path from x_0 to x_1. By Proposition 48.11 there exists a unique lift $\widetilde{\gamma}\colon [0,1] \to M$ of γ to the starting point $\widetilde{x}_0$. By the Change-of-Base Point

Proposition 47.10 (5) the following diagram commutes:

$$\begin{array}{ccc} \pi_1(\widetilde{M}, \gamma(1)) & \xrightarrow{\quad p_* \quad} & \pi_1(M, x_1) \\ \big\downarrow{\scriptstyle \gamma_*} & & \big\downarrow{\scriptstyle \gamma_*} \\ \pi_1(\widetilde{M}, \widetilde{x}_0) & \xrightarrow{\quad p_* \quad} & \pi_1(M, x_0). \end{array}$$

But this implies immediately the promised statement. ■

Definition. Let M be a connected smooth manifold and let $x_0 \in M$.

(1) If M is non-orientable, then we refer to the epimorphism

$$w_1 \colon \pi_1(M, x_0) \ \to \ \pi_1(M, x_0)/p_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) = \mathbb{Z}_2$$

from Proposition 49.7 as the orientation character of M.

(2) If M is orientable, then we define the orientation character of M to be the trivial homomorphism $w_1 \colon \pi_1(M, x_0) \to \mathbb{Z}_2$.

It is worth formulating the following immediate corollary to Proposition 49.7.

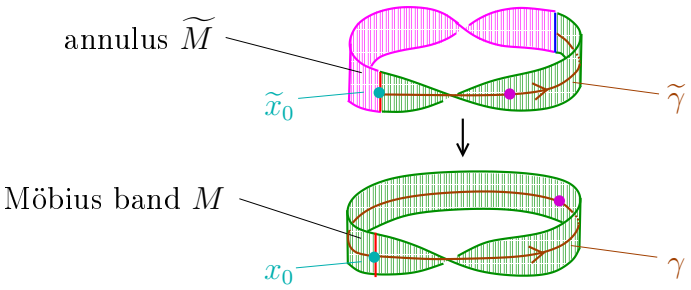
Corollary 49.8. (Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary)

(1) If M is a non-orientable connected non-empty smooth manifold, then there exists an epimorphism $\pi_1(M) \to \mathbb{Z}_2$.

(2) Every simply connected smooth manifold is orientable.

Definition. Let M be a connected smooth manifold and let $\gamma \colon [0,1] \to M$ be a loop in a point x_0. We say γ is orientation-preserving if $w_1^{x_0}(\gamma) = 0$ otherwise we say that γ is orientation-reversing.

Remark. On page 881 we already introduced the notion of orientation-preserving and orientation-reversing loops in a more restrictive setup. It follows immediately from Proposition 49.10 below that the two definitions agree on the type of loops that are covered by both definitions.

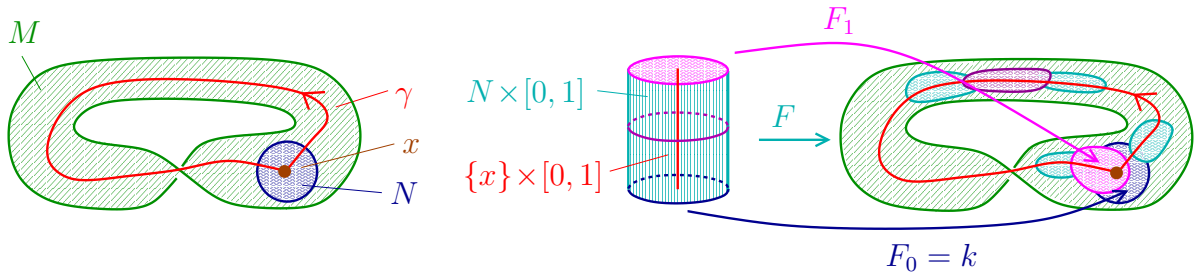


The following lemma gives a practical criterion for determining whether or not a loop is orientation-preserving.

Lemma 49.9. Let M be a connected smooth manifold. As before we denote by $p \colon \widetilde{M} \to M$ the orientation covering provided by Proposition 49.4. Let $x_0 \in M$ be a point and let $\gamma \colon [0,1] \to M$ be a loop in x_0. We pick $\widetilde{x}_0 \in p^{-1}(x_0)$ and we denote by $\widetilde{\gamma} \colon [0,1] \to \widetilde{M}$ the unique lift of γ, provided by Proposition 48.11, to the starting point x_0. Then

$$\begin{array}{rcl} \gamma \text{ is } \textit{orientation-preserving} & \iff & \widetilde{\gamma}(1) = \widetilde{\gamma}(0) \\ \gamma \text{ is } \textit{orientation-reversing} & \iff & \widetilde{\gamma}(1) \neq \widetilde{\gamma}(0). \end{array}$$

Proof. This lemma follows immediately from Lemma 48.15. ■



Example. Let M be the Möbius band and let $\widetilde{M}$ be the annulus. We consider the 2-fold covering $p \colon \widetilde{M} \to M$ that is defined on page 1070. Note that by the Orientation Covering-Proposition 49.5 we know that this covering is just an incarnation of the orientation covering. We pick a point in M and we denote by γ a loop that goes "once around M". The lift of γ is not a loop, hence it follows from Lemma 49.9 that γ is orientation-reversing.

The following proposition hopefully justifies the names "orientation-preserving" and "orientation-reversing" for loops.

Proposition 49.10. Let M be a smooth manifold, let $\gamma\colon [0,1] \to M$ be a smooth loop at a point $x \in M$ and let N be a codimension-zero submanifold of M with $x \in N \setminus \partial N$. We denote by $k\colon N \to M$ the inclusion map. Finally let $F\colon N \times [0,1] \to M$ be a smooth isotopy with $F_0 = k$ such that for each $t \in [0,1]$ we have $F_t(x) = \gamma(t)$. Then[512]

$$(\mathrm{D}k_x)^{-1} \circ \mathrm{D}(F_1)_x\colon \mathrm{T}_xN \to \mathrm{T}_xN \text{ is orientation-preserving} \quad \Longleftrightarrow \quad \gamma \text{ is orientation-preserving.}$$

The proof of Proposition 49.10 rests squarely on the shoulders of the following rather technical lemma.

Auxiliary Lemma 49.11. Let M be a smooth manifold. We denote by $p\colon \widetilde{M} \to M$ the orientation cover. Let $\gamma\colon [0,1] \to M$ be a smooth loop at some point $x \in M$ and let N be a codimension-zero submanifold of M with $x \in N \setminus \partial N$. We denote by $k\colon N \to M$ the inclusion map. Let $F\colon N \times [0,1] \to M$ be a smooth isotopy with $F_0 = k$ such that for each $t \in [0,1]$ we have $F_t(x) = \gamma(t)$. We pick an orientation $\mathcal{O}_x$ of T_xN and we denote by $\widetilde{\gamma}\colon [0,1] \to \widetilde{M}$ the unique lift of $\gamma\colon [0,1] \to M$ to the starting point $(x, \mathrm{D}\,k_x(\mathcal{O}_x))$. Then for each $t \in [0,1]$ the map $(\mathrm{D}p_{\widetilde{\gamma}(t)})^{-1} \circ \mathrm{D}(F_t)_x\colon \mathrm{T}_xN \to \mathrm{T}_{\widetilde{\gamma}(t)}\widetilde{M}$ is orientation-preserving.

Proof of Auxiliary Lemma 49.11. We consider the following two subsets of $[0,1]$:

$$\begin{aligned} A &:= \{t \in [0,1] \,|\, (\mathrm{D}p_{\widetilde{\gamma}(t)})^{-1} \circ \mathrm{D}(F_t)_x\colon \mathrm{T}_xN \to \mathrm{T}_{\widetilde{\gamma}(t)}\widetilde{M} \text{ is orientation-preserving}\} \\ B &:= \{t \in [0,1] \,|\, (\mathrm{D}p_{\widetilde{\gamma}(t)})^{-1} \circ \mathrm{D}(F_t)_x\colon \mathrm{T}_xN \to \mathrm{T}_{\widetilde{\gamma}(t)}\widetilde{M} \text{ is orientation-reversing}\}. \end{aligned}$$

[512] On page 674 we defined what it means for an *automorphism* of a finite dimensional real vector space to be orientation-preserving.

We want to show that $A = [0,1]$. By the choice of the lift $\widetilde{\gamma}$ and since $F_0 = k$ we know that $0 \in A$. By the Interval-Connectedness Proposition 2.22 we know that the interval $[0,1]$ is connected. Thus it remains to show that A and B are both open subsets of $[0,1]$.

In the following we will show that A is open. The proof that B is open is basically the same. Thus let $t \in A$. Since $p\colon \widetilde{M} \to M$ is a local diffeomorphism we can pick an open neighborhood $\widetilde{U}$ of $\widetilde{\gamma}(t) \in \widetilde{M}$ such that $p(U)$ is an open neighborhood of $\gamma(t)$ and such that the projection $p\colon \widetilde{U} \to U := p(\widetilde{U})$ is a diffeomorphism.

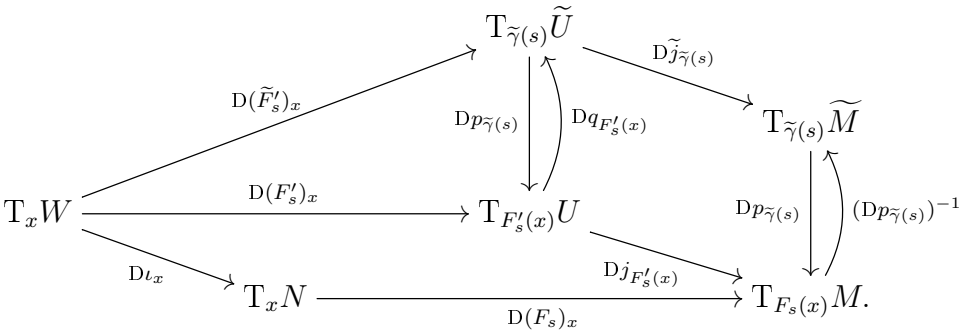
(1) We denote by $q\colon U \to \widetilde{U}$ the inverse of $p\colon \widetilde{U} \to U$.
(2) We denote by $j\colon U \to M$ and $\widetilde{j}\colon \widetilde{U} \to \widetilde{M}$ the inclusion maps.
(3) We equip $\widetilde{U}$ with the standard codimension-zero submanifold orientation from page 684. In other words, we equip $\widetilde{U}$ with the unique orientation such that for each $y \in \widetilde{U}$ the map $\mathrm{D}\widetilde{j}_y\colon \mathrm{T}_y\widetilde{U} \to \mathrm{T}_y\widetilde{M}$ is orientation-preserving.

Since $F\colon N \times [0,1] \to M$ is continuous and since U is an open subset of M we know that $F^{-1}(U)$ is an open neighborhood of (x,t). Using the fact that $x \notin \partial N$ we see that we can pick a product neighborhood $W \times [a,b]$ of (x,t) with the following properties:

(1) We have $(x,t) \in W \times [a,b] \subset F^{-1}(U)$.
(2) $W \subset N \setminus \partial N$ is an open subset that is diffeomorphic to an open ball.
(3) $[a,b] \subset [0,1]$ is a neighborhood of $t \in [0,1]$.

Next we introduce a few more players:

- We denote by $\iota\colon W \to N$ the inclusion map.
- Since W is diffeomorphic to an open ball we know that W is orientable. We equip it with the unique orientation such that $\mathrm{D}\iota_x\colon \mathrm{T}_xW \to \mathrm{T}_xN$ is orientation-preserving.
- We denote by $F'\colon W \times [a,b] \to U$ the restriction of $F\colon N \times [0,1] \to M$ to $W \times [a,b]$.
- We consider the map

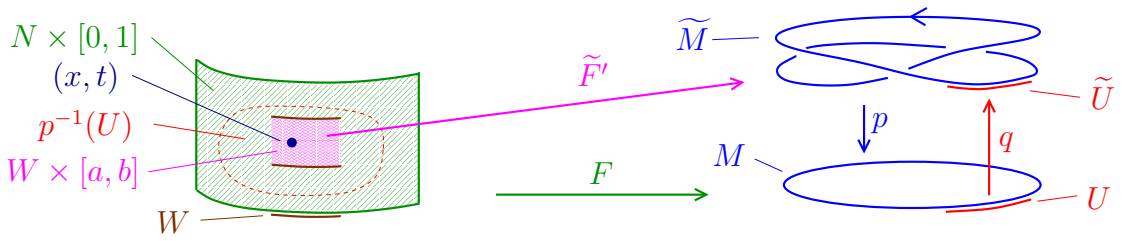


$$\begin{aligned} \widetilde{F}'\colon W \times [a,b] &\to \widetilde{U} \\ (w,s) &\mapsto q(F'(w,s)) = (q \circ F'_s)(w). \end{aligned}$$

Since q is a diffeomorphism we see that $\widetilde{F}'$ is a smooth isotopy.

Claim. For $s \in [a,b]$ we have

$$\text{the map } \mathrm{D}\widetilde{F}'_s\colon \mathrm{T}_xW \to \mathrm{T}_{\widetilde{\gamma}(s)}\widetilde{U} \text{ is orientation-preserving} \quad \Longleftrightarrow \quad s \in A.$$



Proof. To prove the claim we consider the following diagram:

Note that the above diagram commutes by the functoriality of the differential and the fact that $\widetilde{F}'_s = q \circ F'_s \colon W \to \widetilde{U}$, $j \circ F'_s = F_s \circ \iota$, $p \circ \widetilde{j} = j \circ p \colon \widetilde{U} \to M$ and $q = p^{-1} \colon \widetilde{U} \to U$. It follows from the commutativity of the diagram that

$$\underbrace{\mathrm{D}\widetilde{j}_{\widetilde{\gamma}(s)}}_{\substack{\text{orientation-preserving}\\ \text{by definition of the}\\ \text{orientation on } \widetilde{U}}} \circ \mathrm{D}\widetilde{F}'_s \circ \underbrace{(\mathrm{D}\iota_x)^{-1}}_{\substack{\text{orientation-preserving}\\ \text{by definition of the}\\ \text{orientation of } \mathrm{T}_x W}} = \underbrace{(\mathrm{D}p_{\widetilde{\gamma}(s)})^{-1} \circ \mathrm{D}(F_s)_x}_{\substack{\text{orientation-preserving}\\ \text{precisely if } s \in A}} \colon \mathrm{T}_x N \to \mathrm{T}_{\widetilde{\gamma}(t)}\widetilde{M}.$$

The claim follows immediately from this observation. ⊞

Now we can easily conclude the proof of the lemma.

(1) Since $t \in A$ we obtain from the claim that $\widetilde{F}'_t \colon W \to \widetilde{U}$ is orientation-preserving at x.
(2) It follows from the Basics-of-Orientations Lemma 25.13 that $\widetilde{F}'_t \colon W \to \widetilde{U}$ is orientation-preserving.
(3) It follows from the Smooth Isotopy-Orientation Proposition 34.2 that $\widetilde{F}'_s \colon W \to \widetilde{U}$ is orientation-preserving for all $s \in [a,b]$.
(4) It follows from (3) that the differential $\mathrm{D}\widetilde{F}'_s \colon \mathrm{T}_x W \to \mathrm{T}_{\widetilde{\gamma}(s)}\widetilde{U}$ is orientation-preserving for all $s \in [a,b]$.
(5) It follows from (4) and the claim that $[a,b] \subset A$.
(6) Since $[a,b]$ is a neighborhood of $t \in [0,1]$ we now deduce from the JH-Lemma 1.7 that A is indeed an open subset of $[0,1]$. ■

Proof of Proposition 49.10. Let M be a smooth manifold. Furthermore let $\gamma \colon [0,1] \to M$ be a smooth loop at a point $x \in M$ and let N be a codimension-zero submanifold of M with $x \in N \setminus \partial N$. We denote by $k \colon N \to M$ the inclusion map. Finally let $F \colon N \times [0,1] \to M$ be a smooth isotopy with $F_0 = k$ such that for each $t \in [0,1]$ we have $F_t(x) = \gamma(t)$. We set $\Phi = F_1 \colon N \to M$ and we set

$$\epsilon := \begin{cases} +1, & \text{if } \gamma \text{ is orientation-preserving,} \\ -1, & \text{if } \gamma \text{ is orientation-reversing.} \end{cases}$$

We need to show that

$$(\mathrm{D}k_x)^{-1} \circ \mathrm{D}\Phi_x \colon \mathrm{T}_x N \to \mathrm{T}_x N \text{ is orientation-preserving} \iff \epsilon = 1.$$

We pick an orientation $\mathcal{O}_x$ of $\mathrm{T}_x N$ and we denote by $\widetilde{\gamma} \colon [0,1] \to \widetilde{M}$ the unique lift of $\gamma \colon [0,1] \to M$ to the starting point $(x, \mathrm{D}\,k_x(\mathcal{O}_x))$. Now we see that

$$\begin{aligned} \mathrm{D}\Phi_x(\mathcal{O}_x) &= \mathrm{D}p_{(x,\epsilon\cdot \mathrm{D}k_x(\mathcal{O}_x))} \circ (\mathrm{D}p_{(x,\epsilon\cdot \mathrm{D}k_x(\mathcal{O}_x))})^{-1} \circ \mathrm{D}\Phi_x(\mathcal{O}_x) \\ &\underset{\uparrow}{=} \mathrm{D}p_{(x,\epsilon\cdot \mathrm{D}k_x(\mathcal{O}_x))}(\text{orientation of } \widetilde{M} \text{ at } (x, \epsilon \cdot \mathrm{D}k_x(\mathcal{O}_x))) \underset{\uparrow}{=} \epsilon \cdot \mathrm{D}k_x(\mathcal{O}_x). \end{aligned}$$

by Lemma 49.11 (1) applied to $t = 1$, note that $\gamma(1) = (x, \epsilon \cdot \mathrm{D}k_x(\mathcal{O}_x))$ and $\Phi = F_1$

by Proposition 49.4

But this is precisely what we needed to show. ■

49.5. **Orientation flipping diffeotopies II.** In this section we will give a new proof of the Orientation-Flipping Proposition 37.4. Before we can restate and reprove said proposition let us recall the following definition from page 822.

Definition. Let X be a topological space. We say that a homotopy $F\colon X \times [0,1] \to X$ has compact support if there exists a compact subset $K \subset X$ such that $F(x,t) = x$ for all $x \notin K$ and all $t \in [0,1]$.

Now we can recall the Orientation-Flipping Proposition 37.4.

Proposition 37.4. (Orientation-Flipping Proposition) Let M be a non-orientable connected smooth manifold and let $X, Y \subset M \setminus \partial M$ be two disjoint finite subsets. There exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:

(1) $F_0 = \mathrm{id}$.
(2) F has compact support.
(3) F is a diffeotopy rel $\partial M \cup Y$.
(4) $\Phi := F_1$ is the identity on $X \cup Y$.
(5) The map $\Phi := F_1$ has the following properties:
  (a) For each $x \in X$ the map $\mathrm{D}\Phi_x\colon \mathrm{T}_x M \to \mathrm{T}_x M$ is orientation-reversing.
  (b) For each $y \in Y$ the map $\mathrm{D}\Phi_y\colon \mathrm{T}_y M \to \mathrm{T}_y M$ is orientation-preserving.

Remark. Our first proof of the Orientation-Flipping Proposition 37.4 rested on the Isotopy Extension Theorem 36.1. Our new proof only requires the existence of the orientation cover. Our new proof also has the big advantage that it can be generalized to topological manifolds. We refer to page 2342 for a few more details.

Our new proof of the Orientation-Flipping Proposition 37.4 is in many ways similar to the previous proof. In particular it rests on elementary two auxiliary lemmas which we now recall.

Auxiliary Lemma 37.5. Let X be a topological manifold, let $A \subset X$ be a closed subset and let $F\colon X \times [0,1] \to X$ be a homotopy rel A. If F has compact support, then there exists an open neighborhood U of A such that F is a homotopy rel U.

Auxiliary Lemma 37.6. Let M be a smooth manifold and let U be an open subset of M. Furthermore let $G\colon U \times [0,1] \to U$ be a diffeotopy with compact support K. Then

$$\begin{array}{rcl} \widetilde{G}\colon M \times [0,1] & \to & M \\ (x,t) & \mapsto & \begin{cases} G(x,t), & \text{if } x \in K, \\ x, & \text{if } x \notin K \end{cases} \end{array}$$

is a diffeotopy of M.

Again all the work for the proof of the Orientation-Flipping Proposition 37.4 is now done in the proof of the following auxiliary lemma, which deals with the case that $\#X = 1$.

Auxiliary Lemma 37.7. Let M be a connected *non-orientable* smooth manifold. Furthermore let $Y \subset M$ be a finite set and let $x \in M \setminus \partial M$ be a point with $x \notin Y$. There exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:

(1) $F_0 = \mathrm{id}$.

(2) F has compact support.
(3) F is a diffeotopy rel $\partial M \cup Y$.
(4) $\Phi := F_1$ is the identity on $\{x\} \cup Y$.
(5) The map $\Phi := F_1$ has the following properties:
  (a) The map $\mathrm{D}\Phi_x \colon \mathrm{T}_x M \to \mathrm{T}_x M$ is orientation-reversing.
  (b) For each $y \in Y$ the map $\mathrm{D}\Phi_y \colon \mathrm{T}_y M \to \mathrm{T}_y M$ is orientation-preserving.

Proof. New proof of Lemma 37.7] Let M be a connected *non-orientable* smooth manifold. Note that by the Smooth 1-Dimensional Manifold Classification Theorem 22.7 we know that $\dim(M) \geq 2$. We denote by $p \colon \widetilde{M} \to M$ the orientation covering from page 1109. We recall that by Propositions 49.4 and 49.5 this covering has the following properties:

(O1) The map p is a local diffeomorphism. In particular for each $a \in \widetilde{M}$ the differential $\mathrm{D}p_a \colon \mathrm{T}_a\widetilde{M} \to \mathrm{T}_{p(a)}M$ is an isomorphism.
(O2) Our hypothesis that M is non-orientable implies that $\widetilde{M}$ is connected.

Now let $Y \subset M$ be a finite set and let $x \in M \setminus \partial M$ with $x \notin Y$.

(a) We pick an orientation $\mathcal{O}_x$ for $\mathrm{T}_x M$.
(b) We set $W := M \setminus Y$ and $\widetilde{W} := p^{-1}(M \setminus Y)$. Since Y is finite we see that Y and $p^{-1}(Y)$ are closed subsets. It follows from Lemmas 19.19 and 19.20 that W and $\widetilde{W}$ are smooth manifolds with $\partial W = \partial M$ and $\partial\widetilde{W} = \partial\widetilde{M}$.
(c) Since $p^{-1}(Y)$ is a finite set and since $\dim(\widetilde{W}) = \dim(\widetilde{M}) = \dim(M) \geq 2$ we know by the elementary Exercise 18.16 that $\widetilde{W}$ is also path-connected.
(d) It follows from the Smooth Path-Connectivity Proposition 19.29 together with the Push Away From Boundary Lemma 18.13 that there exists in fact a smooth path $\widetilde{\gamma} \colon [0,1] \to \widetilde{W} \setminus \partial\widetilde{W}$ from $(x, \mathcal{O}_x)$ to $(x, -\mathcal{O}_x)$.

By the Isotopy Extension Theorem 36.1 there exists a diffeotopy $F \colon W \times [0,1] \to W$ with the following properties:

(0) For each $t \in [0,1]$ we have $F_t(x) = (p \circ \widetilde{\gamma})(t)$.
(1) $F_0 = \mathrm{id}$.
(2) F has compact support.
(3) F is a diffeotopy rel ∂W.

Note that it follows from (2), together with Lemma 37.6, that we can extend F to a diffeotopy $F \colon M \times [0,1] \to M$ rel Y on all of M by setting $F(x,t) = x$ for $x \notin W$. Finally we set $\Phi := F_1 \colon M \to M$.

By design F has properties (1), (2) and (3). Furthermore note that by Lemma 37.5 we know that F is actually a diffeotopy rel an open neighborhood of Y. This implies that for each $y \in Y$ we have $\mathrm{D}\Phi_y = \mathrm{id}_{\mathrm{T}_y M}$. Thus (5b) is also satisfied. Since $(p \circ \widetilde{\gamma})(1) = x$ we also see that $\Phi(x) = x$. Together with the above discussion this shows that Φ is the identity on $\{x\} \cup Y$. We thus verified that (4) holds.

It remains to show that (5a) holds. This statement is fortunately taken care of by Proposition 49.10. Indeed, we just need to apply Proposition 49.10 to $N = M$ and the smooth loop $p \circ \widetilde{\gamma} \colon [0,1] \to M$, which is orientation-reversing by Lemma 49.9. ∎

Proof. New proof of the Orientation-Flipping Proposition 37.4] Let $x_1, \ldots, x_k$ be the elements of X. It follows from the ever useful Smooth Isotopy Transitivity Proposition 33.3

that it suffices to flip the signs of the points $x_1, \dots, x_k$ one-by-one. But this can be done by applying Lemma 37.7 altogether k times, namely to the points x_i and the sets $Y_i := Y \cup \{x_1, \dots, \widehat{x_i}, \dots, x_k\}$. ■

Exercises for Chapter 49.

Exercise 49.1.

(a) Let π be a group. Show that every index 2 subgroup of π is normal.
(b) Give an example of a group π together with a subgroup of index 3 that is not normal in π.
(c) Show that if G is a group with two elements, then there exists a *unique* isomorphism $G \to \mathbb{Z}_2$.
(d) What is the smallest $n \in \mathbb{N}$ such that there exists a group with n elements which does not admit a *unique* isomorphism $G \to \mathbb{Z}_n$?
(e) What is the smallest $n \in \mathbb{N}$ such that there exists a group G with n elements which does not admit an isomorphism $G \to \mathbb{Z}_n$?

Exercise 49.2. Let $f\colon S^1 \to S^1$ be a map with $f(1) = 1$. We denote by $p\colon \mathbb{R} \to S^1$ the covering that is given by $t \mapsto \exp(\mathrm{i}t)$.

(a) Show that there exists a unique map $\widetilde{f}\colon \mathbb{R} \to \mathbb{R}$ with $f(0) = 0$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathbb{R} & \xrightarrow{\widetilde{f}} & \mathbb{R} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ S^1 & \xrightarrow{f} & S^1. \end{array}$$

(b) Suppose that f is a diffeomorphism. Show that the map $\widetilde{f}$ from (a) is also a diffeomorphism.

Exercise 49.3. Let $f\colon M \to N$ be a smooth map between two smooth manifolds. We assume that f is a covering of topological spaces and we assume that f is a local diffeomorphism. Does it follow that f is a covering of smooth manifolds?

Exercise 49.4.

(a) We consider the following commutative diagram

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{\widetilde{f}} & \widetilde{N} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ M & \xrightarrow{f} & N \end{array}$$

of maps between smooth manifolds $\widetilde{M}$, M, $\widetilde{N}$ and N. We assume that p and q are covering maps of smooth manifolds and we assume that p and q have the same finite degree. Show that f is a diffeomorphism if and only if $\widetilde{f}$ is a diffeomorphism.
(b) Let M and N be smooth manifolds and let $f\colon M \to N$ be a diffeomorphism. We denote by $p\colon \widetilde{M} \to M$ and $q\colon \widetilde{M} \to M$ the orientation coverings of M and N. Show

that there exists an orientation-preserving diffeomorphism $\widetilde{f}\colon \widetilde{M} \to \widetilde{N}$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{\widetilde{f}} & \widetilde{N} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ M & \xrightarrow{f} & N. \end{array}$$

Exercise 49.5. Let K be the Klein bottle and let $x \in K$. Describe an explicit self-diffeomorphism $f\colon K \to K$ with $f(x) = x$ such that $\mathrm{D}f_x\colon \mathrm{T}K_x \to \mathrm{T}K_x$ is orientation-preserving.

Exercise 49.6. Let $p\colon T \to K$ be the 2-fold covering of the Klein bottle by the torus that we discussed on page 1070. Give an example of a smooth map $f\colon K \to K$ such that there is no map $\widetilde{f}\colon T \to T$ which makes the following diagram commute:

$$\begin{array}{ccc} T & \xrightarrow{\widetilde{f}} & T \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ K & \xrightarrow{f} & K. \end{array}$$

Remark. This exercise shows that not every self-map of a smooth manifold gives rise to a self-map of its orientation cover.

Exercise 49.7. Let M be an oriented n-dimensional smooth manifold, let N be a non-orientable connected n-dimensional smooth manifold and let $f\colon M \to N$ be a smooth embedding. We denote by $p\colon \widetilde{N} \to N$ the orientation-covering from the Orientation Covering-Proposition 49.5. Show that there exists an orientation-preserving smooth embedding $g\colon M \to \widetilde{N}$ with $p \circ g = f$.

Exercise 49.8. Let $f\colon M \to N$ be an immersion between two smooth manifolds without boundary and of the same dimension.

(a) We suppose that M and N are compact, non-empty and connected. Show that f is a covering map.
Hint. Use the Inverse Mapping Theorem 24.1.

(b) Does the conclusion of (a) still hold if instead we only assume that M and N are connected and that f is surjective?

Exercise 49.9. Let M and $\widetilde{M}$ be closed oriented connected non-empty smooth manifolds and let $p\colon \widetilde{M} \to M$ be a finite covering. We denote by $\deg(p) \in \mathbb{Z}$ the degree as defined on page 899. Show that $\deg(p) = [\widetilde{M} : M]$.

Exercise 49.10. Let M be a smooth manifold. We denote by $\iota\colon \partial M \to M$ the inclusion. Show that there exists a unique natural diffeomorphism $\partial\widetilde{M} \to \widetilde{\partial M}$ such that the following diagram commutes:

$$\begin{array}{ccccc} & & \overset{\widetilde{\iota}}{\frown} & & \\ \widetilde{\partial M} & \longrightarrow & \partial\widetilde{M} & \hookrightarrow & \widetilde{M} \\ {\scriptstyle p_{\partial M}}\downarrow & & & & \downarrow{\scriptstyle p_M} \\ \partial M & & \xrightarrow{\iota} & & M. \end{array}$$

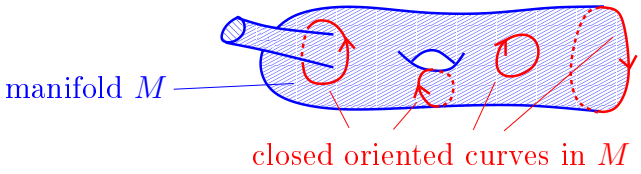
Exercise 49.11. Let $k \in \mathbb{N}$. On page 266 we introduced the non-orientable surface N_k of genus k. The orientation cover of N_k is diffeomorphic to a surface of some genus g. Try to determine g in terms of k.

Exercise 49.12. Let M be a smooth manifold and let $p\colon \widetilde{M} \to M$ be the orientation covering. Show that

$$\begin{aligned}\#\,\text{boundary components of } \widetilde{M} \;\;=\;\; & \#\,\text{non-orientable boundary components of } M \\ & +2\cdot \#\,\text{orientable boundary components of } M.\end{aligned}$$

Exercise 49.13. Let M and N be two connected smooth manifolds, let $f\colon M \to N$ be a local diffeomorphism and finally let $x_0 \in M$. We denote by $w_1^{x_0}(M) \in \operatorname{Hom}(\pi_1(M,x_0),\mathbb{Z}_2)$ and $w_1^{f(x_0)}(N) \in \operatorname{Hom}(\pi_1(N,f(x_0)),\mathbb{Z}_2)$ the corresponding orientation characters. Show that

$$w_1^{x_0}(M) \;=\; w_1^{f(x_0)}(N) \circ (f_*\colon \pi_1(M,x_0) \to \pi_1(N,f(x_0))) \;\in\; \operatorname{Hom}(\pi_1(M,x_0) \to \mathbb{Z}_2).$$



50. Homotopies and fundamental groups

In this chapter we will see that homotopy equivalent topological spaces have isomorphic fundamental groups. In some instances this fact will allow us to reduce the calculation of fundamental groups to some of our earlier calculations.

50.1. Closed oriented curves and fundamental groups.

The following definition gets used frequently throughout the notes.

Definition. Let M be a smooth manifold. A closed (oriented) curve in M is a closed (oriented) connected 1-dimensional submanifold either of ∂M or of M.

Convention. Often we just write "curve" instead of "closed curve".

Remark.

(1) Note that the boundary ∂M a smooth manifold M is *not* a submanifold of M. In particular, if M is a 2-dimensional smooth manifold and C is a closed boundary component, then C is not a submanifold of M, but it is a closed curve in M in the above sense.
(2) On occasions, when we deal with explicit examples, we will use gentle generalizations of the above notion of a closed oriented curve, which in practice should not cause any confusion.

Closed (oriented) curves in a given smooth manifold M have the nice feature that they are easy to draw. But strictly speaking they do not represent elements in $\pi_1(M)$ since elements in $\pi_1(M)$ are represented by *maps* $S^1 \to M$ and not just the images of such maps. Thus we need to clarify the connection between curves and homotopy classes of maps.

The key to this issue is the following lemma, which is also of independent interest.

Lemma 50.1.

(1) Let $f\colon [0,1] \to [0,1]$ be a self-homeomorphism.[513]
   (a) If f is monotonously increasing, then f is isotopic to the map $f(x) = x$.
   (b) If f is monotonously decreasing, then f is isotopic to the map $f(x) = -x$.
(2) Every self-homeomorphism of S^1 is isotopic to the map $f(z) = z$ or to the map $g(z) = \overline{z}$.
(3) Let $f\colon S^1 \to S^1$ be a diffeomorphism. If f is orientation-preserving, then f is diffeotopic to the identity, otherwise f is diffeotopic to the reflection $r\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, -y)$.

Proof. We proved Statements (1) and (2) in Exercise 14.7 or alternatively in Exercise 48.24. We proved Statement (3) in the Diffeotopies-of-S^1-Classification Proposition 34.5. The

[513] It is an elementary real analysis exercise to show that every self-homeomorphism $f\colon [0,1] \to [0,1]$ is either monotonously increasing or monotonously decreasing.

proof of the Diffeotopies-of-S^1-Classification Proposition 34.5 can also be modified easily to take care of Statement (2). ■

Corollary 50.2. Let M be a smooth manifold and let $C \subset M$ be a closed oriented curve in M. Furthermore let $x_0 \in C$. For any two orientation-preserving diffeomorphisms $\alpha, \beta\colon S^1 \to C$ with $\alpha(1) = \beta(1) = x_0$ we have $[\alpha] = [\beta] \in \pi_1(M, x_0)$.

Proof. It is fairly straightforward to prove the corollary using Lemmas 50.1 (1) and 47.3. We leave the task of filling in the details to the reader. ■

Convention. Let M be a smooth manifold and let $C \subset M$ be a closed oriented curve in M. Throughout these notes we use that Corollary 50.2 allows us to view C unambiguously as an element in $\pi_1(M, x_0)$ for any base point $x_0 \in C$.

50.2. **The fundamental groups of homotopy equivalent topological spaces.** Now we will see that homotopy equivalent topological spaces have isomorphic fundamental groups. On numerous occasions this fact will often greatly simplify the calculation of fundamental groups.

Proposition 50.3. (Homotopy-π_1-Proposition)

(1) Let $f, g\colon X \to Y$ be two maps between topological spaces and let $x_0 \in X$. If f and g are homotopic, then there exists a path $\alpha\colon [0,1] \to Y$ from $f(x_0)$ to $g(x_0)$ such that the following diagram commutes:

$$\begin{array}{ccc} & \overset{g_*}{\nearrow} & \pi_1(Y, g(x_0)) \\ \pi_1(X, x_0) & & \Big\downarrow{\scriptstyle \alpha_*}\ {\scriptstyle [s] \mapsto [\alpha * s * \overline{\alpha}]} \\ & \underset{f_*}{\searrow} & \pi_1(Y, f(x_0)). \end{array}$$

Here the vertical map is the isomorphism given by the Change-of-Base Point Proposition 47.10. In particular

$$\begin{array}{c} f_*\colon \pi_1(X, x_0) \to \pi_1(Y, f(x_0)) \\ \text{is an isomorphism} \end{array} \iff \begin{array}{c} g_*\colon \pi_1(X, x_0) \to \pi_1(Y, g(x_0)) \\ \text{is an isomorphism.} \end{array}$$

The analogous statement holds if we replace "isomorphism" by "epimorphism" or "monomorphism". Furthermore, the following two refinements hold:

(a) If f and g are homotopic rel x_0, then $f_* = g_*$.[514]

(b) If $f(x_0) = g(x_0)$ and if the maps f and g are homotopic, then there exists an $\alpha \in \pi_1(Y, f(x_0))$ such that $f_*(z) = \alpha \cdot g_*(z) \cdot \alpha^{-1}$ for every $z \in \pi_1(X, x_0)$.

(2) Let $f\colon X \to Y$ be a map between topological spaces and let $x_0 \in X$. If f is a homotopy equivalence, then the induced map

$$f_*\colon \pi_1(X, x_0) \ \to \ \pi_1(Y, f(x_0))$$

is an isomorphism.

(3) If X is contractible topological space, then for any $x_0 \in X$ we have $\pi_1(X, x_0) = 0$.

[514] This statement can be viewed as a special case of Lemma 14.6.

Example. For any $n \geq 2$ and any $Q \in \mathbb{R}^n$ we have

$$\begin{array}{ccccccc} & & & & \text{by the Deformation Retract-Homotopy Equivalence Lemma 15.5, Exercise 15.13 and the Homotopy-}\pi_1\text{-Proposition 50.3 (2)} & & \\ & & & & \downarrow & & \\ \pi_1(\mathbb{R}^n \setminus \{Q\}) & \cong & \pi_1(\mathbb{R}^n \setminus \{0\}) & \cong & \pi_1(S^{n-1}) & \cong & \begin{cases} \mathbb{Z}, & \text{if } n = 2, \\ 0, & \text{if } n \geq 3. \end{cases} \\ & \uparrow & & & & \uparrow & \\ & \text{since } \mathbb{R}^n \setminus \{Q\} \text{ is homeomorphic to } \mathbb{R}^n \setminus \{0\} & & & & \text{by Corollary 48.18 and the Sphere-}\pi_1\text{-Proposition 47.13} & \end{array}$$

Proof.

(1) Let $f, g\colon X \to Y$ be two maps between topological spaces and let $x_0 \in X$. Let $H\colon X \times [0,1] \to Y$ be a homotopy between f and g. We denote by

$$\begin{array}{rcl} \alpha\colon [0,1] & \to & Y \\ t & \mapsto & H(x_0, t) \end{array}$$

the path with which the homotopy H connects the points $H(x_0, 0) = f(x_0)$ and $H(x_0, 1) = g(x_0)$.

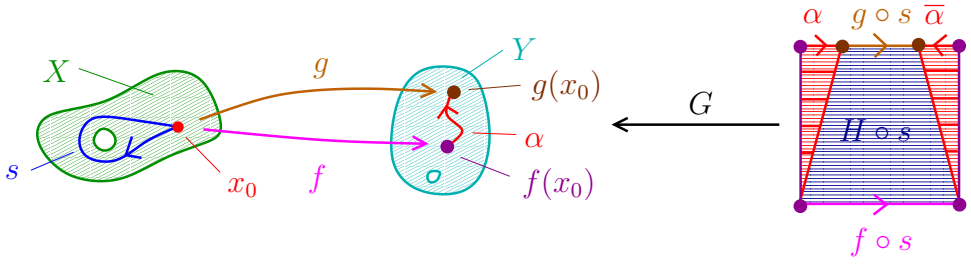
Claim. The maps

$$\begin{array}{rcl} f_*\colon \pi_1(X, x_0) & \to & \pi_1(Y, f(x_0)) \\ [s] & \mapsto & [f \circ s] \end{array} \quad \text{and} \quad \begin{array}{rcl} \pi_1(X, x_0) & \to & \pi_1(Y, f(x_0)) \\ [s] & \mapsto & [\alpha * (g \circ s) * \overline{\alpha}] \end{array}$$

are identical.

Proof. Let $s\colon [0,1] \to X$ be a loop in (X, x_0). We need to show that the loops $f \circ s$ and $\overline{\alpha} * (g \circ s) * \alpha$ are path-homotopic. We consider the map

$$\begin{array}{rcl} G\colon [0,1] \times [0,1] & \to & X \\ (r,t) & \mapsto & \begin{cases} \alpha(4r), & \text{if } r \in \left[0, \frac{1}{4}t\right], \\ H\left(s\left(\frac{r - \frac{1}{4}t}{1 - \frac{1}{2}t}\right), 1 - t\right), & \text{if } r \in \left(\frac{1}{4}t, 1 - \frac{1}{4}t\right), \\ \overline{\alpha}(4r - 3), & \text{if } r \in \left[1 - \frac{1}{4}t, 1\right]. \end{cases} \end{array}$$



Using the Homotopy Stacking Lemma 14.3 it is straightforward to verify that G is indeed a continuous map. Furthermore it follows easily from the definition that the map G satisfies

$$G(0,t) \;=\; G(1,t) \;=\; f(x_0) \quad \text{for all } t \in [0,1]$$

and that it satisfies

$$G(r,0) \;=\; (f \circ s)(r) \quad \text{and} \quad G(r,1) \;=\; (\overline{\alpha} * (g \circ s) * \alpha)(r) \quad \text{for all } r \in [0,1].$$

This observation shows that G is in fact a path-homotopy between the loops $f \circ s$

and $\alpha * (g \circ s) * \overline{\alpha}$[515] in $(Y, f(x_0))$. ⊞

As in the statement of the proposition we consider the following diagram:

$$\begin{array}{ccc} & \xrightarrow{g_*} & \pi_1(Y, g(x_0)) \\ \pi_1(X, x_0) & & \Big\downarrow{\scriptstyle \alpha_*} \; [s] \mapsto [\alpha * s * \overline{\alpha}] \\ & \xrightarrow[f_*]{} & \pi_1(Y, f(x_0)). \end{array}$$

We make the following observations:

(a) It follows from the claim that the diagram commutes.

(b) By the Change-of-Base Point Proposition 47.10 we know that the vertical map is an isomorphism.

(c) It follows from (a) and (b) that f_* is an isomorphism if and only if g_* is an isomorphism.

(d) Now suppose that f and g are homotopic rel x_0. By definition this means that there exists a homotopy H with $H(x_0, t) = f(x_0)$ for all $t \in [0, 1]$. In other words, $\alpha(t) := H(x_0, t)$ is a constant path. It follows from the above that $f_* = g_*$.

(e) If $f(x_0) = g(x_0)$, then α is a loop in $(Y, f(x_0))$, i.e. it defines an element in $\pi_1(Y, y_0)$. Thus we have $[\alpha * (g \circ s) * \overline{\alpha}] = [\alpha] \cdot g_*(s) \circ [\alpha]^{-1}$. By the above commutative diagram we obtain the desired equality.

The analogous statement holds if we replace "isomorphism" by "epimorphism" or "monomorphism".

(2) Let $f\colon X \to Y$ be a map between topological spaces which is a homotopy equivalence. Let $x_0 \in X$ be a point. We pick a homotopy inverse $g\colon Y \to X$ of f. According to our hypothesis we have $g \circ f \simeq \mathrm{id}_X$ and $f \circ g \simeq \mathrm{id}_Y$. It follows from (1) and the functoriality of fundamental groups that $g_* \circ f_*$ is an isomorphism of $\pi_1(X, x_0)$ and that $f_* \circ g_*$ is an isomorphism of $\pi_1(Y, f(x_0))$. Thus it remains to prove the following purely group theoretic claim.

Claim. Let $\alpha\colon A \to B$ and $\beta\colon B \to A$ be group homomorphisms. If $\alpha \circ \beta$ and $\beta \circ \alpha$ are isomorphisms, then α is an isomorphism.

Proof. First note that the fact that $\beta \circ \alpha\colon A \to A$ is an isomorphism implies that α is a monomorphism. Furthermore, the fact that $\alpha \circ \beta\colon B \to B$ is an isomorphism implies that α is an epimorphism. Thus we have shown that α is a monomorphism and an epimorphism, therefore it is an isomorphism. ⊞

(3) This statement is just a frequently used special case of the second statement. ■

In Lemma 2.26 we already saw that the topological spaces $\mathbb{R}$ and $\mathbb{R}^2$ are not homeomorphic. Now we can prove a similar statement in one dimension higher.

Lemma 50.4. The topological spaces $\mathbb{R}^2$ and $\mathbb{R}^3$ are not homeomorphic.

Unfortunately we are still not able to settle the question whether for $k \neq l \geq 3$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ can be homeomorphic. Before we can settle this question we will have to develop a completely new set of tools.

[515] To be precise, G is a homotopy between $f \circ s$ and a suitable parametrization of $\alpha * (g \circ s) * \overline{\alpha}$.

Proof. Let us suppose that there exists a homeomorphism $f\colon \mathbb{R}^2 \to \mathbb{R}^3$. Let $P \in \mathbb{R}^2$ be a point. We put $Q := f(P)$. Then f restricts to a homeomorphism from $\mathbb{R}^2 \setminus \{P\}$ to $\mathbb{R}^3 \setminus \{Q\}$. But then we obtain that

$$\begin{array}{ccccccc} \mathbb{Z} & \cong & \pi_1(\mathbb{R}^2 \setminus \{P\}) & \cong & \pi_1(\mathbb{R}^3 \setminus \{Q\}) & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{page 1125} & & \text{since } f \text{ is a homeomorphism} & & \text{page 1125} & \end{array}$$

Thus we obtained a contradiction. ■

50.3. **The fundamental group of mapping tori.** Let X be a topological space and let $f\colon X \to X$ be a map. On page 467 we introduced the corresponding mapping torus

$$\operatorname{Tor}(X, f) \;:=\; (X \times [0,1])\,/\!\sim \qquad \text{where } (x,0) \sim (f(x),1) \text{ for all } x \in X.$$

Our goal in this section is to determine the fundamental groups of mapping tori. Before we can do so we need to introduce a new concept from group theory.

Definition. Let N be a group, let $k \in \mathbb{N}_0$ and let $\varphi\colon N \to N$ be an isomorphism such that $\varphi^k = \mathrm{id}$.[516] We define the semidirect product of N and $\mathbb{Z}_k$ with respect to φ as the group $N \rtimes_\varphi \mathbb{Z}_k$ where the underlying set is given by the direct product $N \times \mathbb{Z}_k$,[517] but where the group multiplication[518] is given by

$$(h,m) \cdot (h',m') \;:=\; (h \cdot \varphi^m(h'), m + m').$$

If φ is understood from the context, then we drop it from the notation, i.e. we write $N \rtimes \mathbb{Z}_k$ instead of $N \rtimes_\varphi \mathbb{Z}_k$. If $\varphi \neq \mathrm{id}$, then we say that the semidirect product as non-trivial.

Examples.

(1) Let N be a group and $\varphi = \mathrm{id}_N$, then $N \rtimes_{\mathrm{id}} \mathbb{Z} = N \times \mathbb{Z}$ is the direct product of N and $\mathbb{Z}$.

(2) Let $G = \mathbb{Z}_2$ and let $N = \mathbb{Z}_n$ for some $n \in \mathbb{N}_0$. We denote by $\varphi\colon \mathbb{Z}_n \to \mathbb{Z}_n$ the isomorphism that is given by multiplication by -1. Clearly this isomorphism satisfies $\varphi^2 = \mathrm{id}$, thus we can form the semidirect product $\mathbb{Z}_n \rtimes_\varphi \mathbb{Z}_2$, which is called the *$n$-th dihedral group* D_n. It has $2n$ elements. As an example, the third dihedral group D_3 is isomorphic to the permutation group S_3 via the isomorphism [519]

$$\begin{array}{rcl} \Psi\colon \mathbb{Z}_3 \rtimes \mathbb{Z}_2 & \to & S_3 \\ (h,m) & \mapsto & (1\,2\,3)^h \cdot (1\,2)^m. \end{array}$$

[516] Note that this condition is automatically satisfied if $k = 0$, i.e. for any isomorphism φ of any group we always have $\varphi^0 = \mathrm{id}$.

[517] In particular, if N is finite and $k \in \mathbb{N}$, then the cardinality of $N \rtimes \mathbb{Z}_k$ is given by $|N| \cdot k$.

[518] It is an elementary argument to show that $N \rtimes_\varphi \mathbb{Z}_k$ with the given multiplication is indeed a group.

[519] First note that a straightforward calculation shows that $(1\,2)^{-1} \cdot (1\,2\,3) \cdot (1\,2) = (1\,3\,2) = (1\,2\,3)^{-1}$. This implies that also for any $m \in \mathbb{Z}_2$ and $s \in \mathbb{Z}$ we have $(1\,2)^{-m} \cdot (1\,2\,3)^s \cdot (1\,2)^m = (1\,2\,3)^{s(-1)^m}$. Now for any $(h,m),(h',m') \in \mathbb{Z}_n \rtimes_\varphi \mathbb{Z}_2$ we have

$$\begin{aligned} \Psi(h,m)\Psi(h',m') &= (1\,2\,3)^h \cdot (1\,2)^m \cdot (1\,2\,3)^{h'} \cdot (1\,2)^{m'} = (1\,2\,3)^h \cdot (1\,2)^m \cdot (1\,2)^{-m} \cdot (1\,2\,3)^{(-1)^m h'} \cdot (1\,2)^m \cdot (1\,2)^{m'} \\ &= (1\,2\,3)^{h+(-1)^m h'} \cdot (1\,2)^{m+m'} \;=\; \Psi(h + (-1)^m h', m + m') \;=\; \Psi((h,m) \cdot (h',m')). \end{aligned}$$

We have thus shown that Ψ is a homomorphism.

Remark. In Exercise 50.16 we will see that $N = \{(h,0) \mid h \in N\} \subset N \rtimes \mathbb{Z}_k$ is a normal subgroup of $N \rtimes \mathbb{Z}_k$. Put differently, we have $N \triangleleft N \rtimes \mathbb{Z}_k$. This is the reason for the symbol "$\rtimes$" in the notation of the semidirect product.

We have the following elementary lemma.

Lemma 50.5. (Semidirect Product Lemma) Let G be a group and let $\gamma\colon G \to \mathbb{Z}$ be an epimorphism. We pick an element $t \in G$ with $\gamma(t) = 1$ and we write $N := \ker(\gamma)$. We denote by φ the isomorphism

$$\begin{array}{rccl} \varphi\colon N & \to & N \\ h & \mapsto & tht^{-1}. \end{array}$$

Then the map[520]

$$\begin{array}{rccl} \Psi\colon G & \to & N \rtimes_\varphi \mathbb{Z} \\ g & \mapsto & \big(gt^{-\gamma(g)}, \gamma(g)\big) \end{array}$$

is an isomorphism of groups.

Proof. It is straightforward to verify that Ψ is injective and surjective. It remains to show that Ψ is a homomorphism: given $g, h \in G$ we have indeed

$$\begin{aligned} \Psi(g \cdot h) \;=\; (ght^{-\gamma(gh)}, \gamma(gh)) \;&=\; (gt^{-\gamma(g)} \cdot \underbrace{t^{\gamma(g)} \cdot ht^{-\gamma(h)} \cdot t^{-\gamma(g)}}_{=\varphi^{\gamma(g)}(ht^{-\gamma(h)})}, \gamma(g) + \gamma(h)) \\ &=\; (gt^{-\gamma(g)}, \gamma(g)) \cdot (ht^{-\gamma(h)}, \gamma(h)) \;=\; \Psi(g) \cdot \Psi(h). \end{aligned}$$

■

The following proposition shows that the fundamental group of a mapping torus $\mathrm{Tor}(X, f)$ is isomorphic to a semidirect product of $\pi_1(X)$ with $\mathbb{Z}$.

Proposition 50.6. (Mapping Torus-π_1-Proposition) Let X be some non-empty path-connected topological space and furthermore let $f\colon X \to X$ be some homeomorphism. Then there exists an isomorphism $\psi\colon \pi_1(\mathrm{Tor}(X,f)) \cong \pi_1(X) \rtimes \mathbb{Z}$ such that the following diagram commutes

$$\begin{array}{ccccc} \pi_1(X) & \longrightarrow & \pi_1(\mathrm{Tor}(X,f)) & \longrightarrow & \pi_1(S^1) \\ \downarrow & & \cong\big\downarrow \psi & & \big\downarrow \cong \\ \pi_1(X) & \longrightarrow & \pi_1(X) \rtimes \mathbb{Z} & \longrightarrow & \mathbb{Z}. \end{array}$$

Here the top-left horizontal map is induced by the inclusion $X = X \times \{0\} \to \mathrm{Tor}(X,f)$ and the top-right horizontal map is induced by the natural projection $\mathrm{Tor}(X,f) \to S^1$. The bottom-left horizontal map is given by the natural inclusion into the first term of the semidirect product and the bottom-right horizontal map is given by the projection onto the second term of the semidirect product.[521]

Proof. Note that

$$\pi_1(\mathrm{Tor}(X,f)) \underset{\uparrow}{=} \pi_1((X \times \mathbb{R})/\mathbb{Z}_f) \overset{\downarrow}{\cong} \pi_1(X \times \mathbb{R}) \rtimes \mathbb{Z} \underset{\uparrow}{\cong} \pi_1(X) \rtimes \mathbb{Z}.$$

Mapping Torus-of-Homeomorphism Lemma 16.28 — Fundamental Group-via-Actions Theorem 48.16 (2) and Semidirect Product Lemma 50.5 — Homotopy-π_1-Proposition 50.3

[520] Note that $\gamma(gt^{-\gamma(g)}) = \gamma(g) + \gamma(t)(-\gamma(g)) = 0$, i.e. $gt^{-\gamma(g)}$ does indeed lie in $N = \ker(\gamma)$.

[521] Note that both maps on the bottom are group homomorphisms.

Thus we have obtained an isomorphism $\psi\colon \pi_1(\mathrm{Tor}(X,f)) \xrightarrow{\cong} \pi_1(X) \rtimes \mathbb{Z}$. We leave the verification that the given diagram commutes to the reader. ■

Remark. A careful reading of the proof of the proposition shows that we can identify the automorphism in the semidirect product. More precisely, let X be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism. Let x be a base point and let γ be a path from $f(x)$ to x. We denote by φ the automorphism of $\pi_1(X,x)$ that is given by

$$\pi_1(X,x) \xrightarrow{f_*} \pi_1(X,f(x)) \xrightarrow[\text{Prop. 47.10}]{\cong} \pi_1(X,x). \qquad =:\varphi$$

Then $\pi_1(\mathrm{Tor}(X,f)) \cong \pi_1(X,x) \rtimes_\varphi \mathbb{Z}$.

We conclude this section with a discussion of several examples.

Examples.

(1) Let $K = \mathrm{Tor}(S^1, f(z) := \overline{z})$ be the Klein bottle. Then the automorphism $f_* =: \varphi$ of $\pi_1(S^1) = \mathbb{Z}$ is multiplication by -1. It follows from the previous remark[522] that

$$\pi_1(\text{Klein bottle}) \;\cong\; \mathbb{Z} \rtimes_\varphi \mathbb{Z}.$$

(2) Let $A \in \mathrm{GL}(n,\mathbb{Z})$ be a matrix. Recall that in Exercise 48.18 we showed that the map $f(A)\colon \mathbb{R}^n/\mathbb{Z}^n \to \mathbb{R}^n/\mathbb{Z}^n$ given by $[v] \mapsto [Av]$ is a homeomorphism. Furthermore we know that, under the usual identification $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) = \mathbb{Z}^n$ as in the Fundamental Group-via-Actions Theorem 48.16, the induced map $f(A)_*$ on $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) = \mathbb{Z}^n$ is given by multiplication by A. It follows from the above remark that $\pi_1(\mathrm{Tor}(\mathbb{R}^n/\mathbb{Z}^n, f(A))) \cong \mathbb{Z}^n \rtimes_A \mathbb{Z}$. Note that this implies that $\pi_1(\mathrm{Tor}(\mathbb{R}^n/\mathbb{Z}^n, f(A)))$ is solvable.[523]

(3) Let X be a connected topological space. We calculate that

$$\pi_1(X \times S^1) \underset{\text{Mapping Torus-of-id-Lemma 16.24}}{=} \pi_1(\mathrm{Tor}(X, \mathrm{id}_X)) \underset{\text{by the above remark}}{\cong} \pi_1(X) \rtimes_{\mathrm{id}} \mathbb{Z} = \pi_1(X) \times \mathbb{Z} = \pi_1(X) \times \pi_1(S^1).$$

So in this special case we obtain the same result as in the Fundamental Group-of-Product Proposition 48.20.

50.4. **The boundary of 2-dimensional topological manifolds.** The goal of this section is to prove the subtle statement that the boundary of a 2-dimensional topological manifold is what you think it should be. To make sense of this it is perhaps worth reminding us of the definitions from page 511.

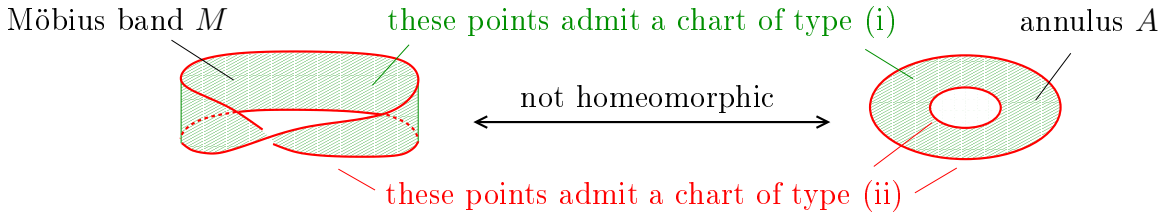
[522] On page 1222 we saw that $\pi_1(K) \cong \langle x, y \,|\, yxyx^{-1}\rangle$. What is an explicit isomorphism between the groups $\langle x, y \,|\, yxyx^{-1}\rangle$ and $\mathbb{Z} \rtimes_\varphi \mathbb{Z}$?

[523] Recall that a group G is solvable if there exist subgroups $G_0 = \{1\} \subset G_1 \subset G_2 \subset \cdots \subset G_k = G$ such that for $i = 0, \ldots, k-1$ the group G_i is normal in G_{i+1} and such that G_{i+1}/G_i is abelian. In our case the filtration is given by $\{0\} \subset \mathbb{Z}^n \subset \mathbb{Z}^n \rtimes_A \mathbb{Z}$.

Definition. Let F be an n-dimensional topological manifold.

(a) An n-dimensional chart for F at a point $x \in X$ is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and V is one of the following:
  (i) V is an open subset of $\mathbb{R}^n$ or
  (ii) V is an open subset of the upper half-space $H := \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$ and $\Phi(x)$ lies on $\partial H = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_n = 0\}$.

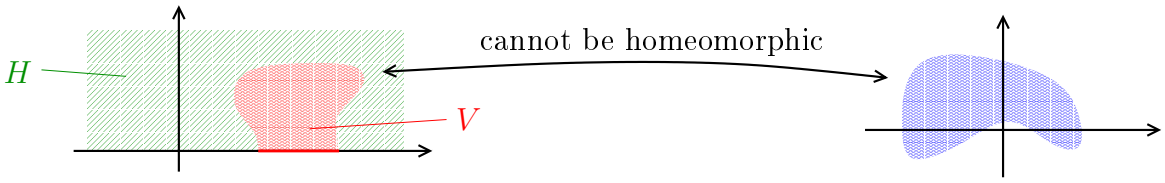
  In the former case we say that Φ is a chart of type (i) in the latter case we say that Φ is a chart of type (ii).



(b) We say that a point x on a topological manifold is a boundary point if x does not admit a chart of type (i). We denote by ∂X the set of all boundary points of X.

Proposition 50.7. Let F be an 2-dimensional topological manifold. The following statements hold:

(1) Every point on F admits either a chart of type (i) or it admits a chart of type (ii).
(2) If F is equipped with a smooth atlas, i.e. if we view F as a smooth manifold, then the boundary of F as a topological manifold agrees with the boundary of F viewed as a topological manifold.
(3) The boundary ∂F is an 1-dimensional topological manifold with empty boundary, i.e. we have $\partial(\partial F) = \varnothing$.



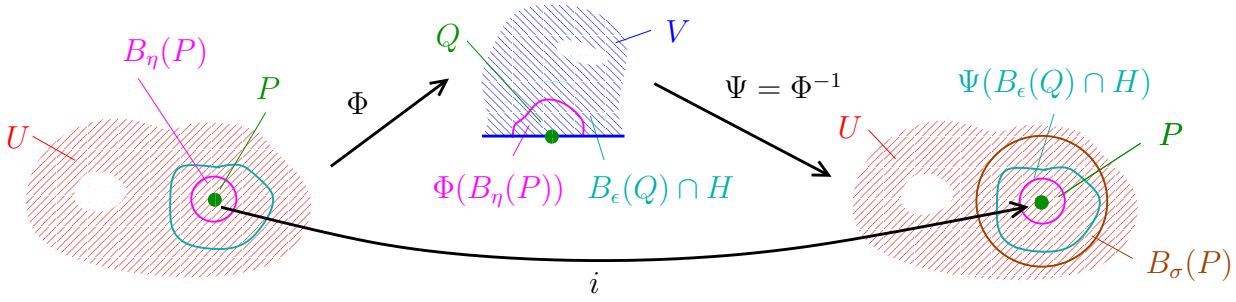
Remark. It might come as a surprise that we do not yet know the statement of the proposition. In fact in the Smooth Manifold Boundary Proposition 19.26 we saw that the boundary of any n-dimensional smooth manifold is an $(n-1)$-dimensional smooth manifold. But we did not show the corresponding statement for topological manifolds. In fact at the moment we can prove the statement only for topological manifolds of dimension *two*. We will deal with the case of higher-dimensional topological manifolds in the Topological Manifold Boundary Proposition 75.2 once we introduced and studied homology groups.

Example. In the figure below we show once again the Möbius band M and the annulus A. Proposition 50.7, together with the Smooth Manifold Boundary Proposition 19.26, says that the boundary of the Möbius band M and the annulus A, *as a topological manifold*, is exactly what we think it should be. In particular we see that ∂M consists of one component whereas ∂A consists of two components. Since homeomorphisms of topological manifolds induced homeomorphisms of their boundaries and since ∂M is not homeomorphic to ∂A we see that the Möbius band M is not homeomorphic to the annulus A.

The key ingredient in the proof of Proposition 50.7 is the following lemma.

Lemma 50.8. Let $H = \{(x, y) \in \mathbb{R}^2 \mid y \geq 0\}$ be the upper half-space in $\mathbb{R}^2$. If V is an open subset of H with $V \cap \partial H \neq \varnothing$, then V is not homeomorphic to an open subset of $\mathbb{R}^2$.

Proof. Let V be an open subset of the upper half-space H which contains at least one point $Q \in \partial H = \{(x,0) \mid x \in \mathbb{R}\}$. Furthermore let U be an open subset of $\mathbb{R}^2$. Suppose there exists a homeomorphism $\Phi\colon U \to V$. We write $\Psi := \Phi^{-1}$ and we write $P = \Psi(Q)$.



Since U is open in $\mathbb{R}^2$ we can pick a $\sigma > 0$ with $B_\sigma(P) \subset U$. Furthermore, since V is open in H and since Ψ is continuous there exists an $\epsilon > 0$ with $B_\epsilon(Q) \cap H \subset V$ and with $\Psi(B_\epsilon(Q)) \subset B_\sigma(P)$. Finally, by the continuity of Φ there exists an $\eta > 0$ with $\Phi(B_\eta(P)) \subset B_\epsilon(Q))$. We refer to the figure below for an illustration. We consider the following commutative diagram of maps

$$\begin{array}{ccc} & (B_\epsilon(Q) \setminus \{Q\}) \cap H & \\ {\scriptstyle \Phi}\nearrow & & \searrow{\scriptstyle \Psi = \Phi^{-1}} \\ B_\eta(P) \setminus \{P\} & \xrightarrow[i]{} & B_\sigma(P) \setminus \{P\}, \end{array}$$

where $i\colon B_\eta(P)\setminus\{P\} \to B_\sigma(P)\setminus\{P\}$ denotes the inclusion map. Now we pick a base point $x \in B_\eta(P) \setminus \{P\}$. By the functoriality of fundamental groups, the above commutative diagram of maps gives rise to the following commutative diagram

$$\begin{array}{ccc} & \pi_1((B_\epsilon(Q) \setminus \{Q\}) \cap H, \Phi(x)) & \\ {\scriptstyle \Phi_*}\nearrow & & \searrow{\scriptstyle \Psi_* = \Phi_*^{-1}} \\ \pi_1(B_\eta(P) \setminus \{P\}, x) & \xrightarrow[i_*]{} & \pi_1(B_\sigma(P) \setminus \{P\}, x). \end{array}$$

We make the following observations:

(1) The topological spaces on the left and on the right are homotopy equivalent to S^1, in particular the fundamental groups are non-trivial.
(2) By Exercise 15.4 we know that the inclusion map $B_\eta(P) \setminus \{P\} \to B_\sigma(P) \setminus \{P\}$ is a homotopy equivalence, therefore it follows from the Homotopy-π_1-Proposition 50.3 (2) that the inclusion induced map $i_*\colon \pi_1(B_\eta(P) \setminus \{P\}, x) \to \pi_1(B_\sigma(P) \setminus \{P\}, x)$ is an isomorphism.

(3) The topological space $(B_\epsilon(Q) \setminus \{Q\}) \cap H$ is star-shaped[524], which implies by the discussion on page 1058 that $\pi_1((B_\epsilon(Q) \setminus \{Q\}) \cap H, \Phi(x)) = 0$.

Summarizing we just showed that an isomorphism of non-trivial groups factors through the trivial group. This is not possible and hence we have obtained the desired contradiction. ■

Now we can turn to the proof of Proposition 50.7.

Proof of Proposition 50.7. Let F be an 2-dimensional topological manifold.

(1) Let x be a point on F. We need to show that x admits either a chart of type (i) or it admits a chart of type (ii). Suppose that x admits a chart $\Phi\colon U \to V$ of type (i) and also a chart $\Psi\colon X \to Y$ of type (ii). Then $\Phi \circ \Psi^{-1}\colon \Psi(U \cap X) \to \Phi(U \cap X)$ would give rise to a homeomorphism from an open set of H containing a point on $\partial H = \{(x, 0) \mid x \in \mathbb{R}\}$ to an open set in $\mathbb{R}^2$. But by Lemma 50.8 such a homeomorphism cannot exist.

(2) Now suppose that F is equipped with a smooth atlas. For the purpose of this proof we write $\partial^{\text{top}}F$ and $\partial^{\text{sm}}F$. By the definitions on pages 511 and 545 we have

$$\begin{aligned} \partial^{\text{top}}F &= \text{all points that do not admit a chart of type (i)} \\ \partial^{\text{sm}}F &= \text{all points that do not admit a chart of type (i) from the smooth atlas.} \end{aligned}$$

By definition we have $\partial^{\text{top}}F \subset \partial^{\text{sm}}F$. Now let $P \in \partial^{\text{sm}}F$. This means that P does not admit a chart of type (i) from the smooth atlas. By definition of a smooth manifold it admits a chart of type (ii). But by (1) this means that it cannot admit any chart of type (i). Thus we see that $P \in \partial^{\text{sm}}F$.

(3) We need to show that the boundary ∂F is a 1-dimensional topological manifold which has no boundary, i.e. such that $\partial Y = \varnothing$. First let $P \in F$ be a point on the boundary. Let $\Phi\colon U \to V$ be a chart of type (ii) for P. It follows from the (1) and the definitions that $\partial F \cap U = \Phi^{-1}(\partial H \cap V)$. Thus we see that Φ restricts to a chart $\Phi\colon \partial F \cap U \to \partial H \cap V$ of type (i), here we view $\partial H \cap V$ as an open subset of $\partial H = \mathbb{R}$. This shows that ∂F admits a 1-dimensional atlas where all charts are charts of type (i). Since F is second-countable and Hausdorff we obtain from the Second Countability Lemma 9.1 (2) and Lemma 1.14 that ∂F is also second-countable and Hausdorff. ■

50.5. The wedge of pointed topological spaces.

Definition. Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces.

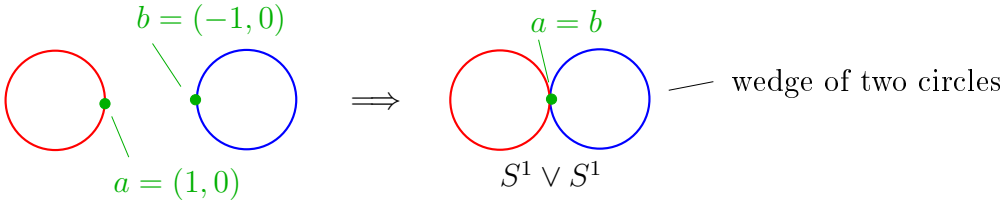
(1) We refer to

$$\bigvee_{i \in I} X_i \;:=\; \bigvee_{i \in I} (X_i, x_i) \;:=\; \Big(\bigsqcup_{i \in I} X_i\Big)/\!\sim \qquad \text{where } x_i \sim x_j \text{ for all } i, j \in I$$

as the wedge of the pointed topological spaces (X_i, x_i). We refer to the point given by the identifications as the wedge point. If we do not say anything else it will be denoted by $*$.

(2) Let Y be a topological space and suppose that we are given a family of maps $\{f_i\colon X_i \to Z\}_{i \in I}$ such that for every $i, j \in I$ we have $f_i(x_i) = f_j(x_j)$. We define the map

[524] Why is that?



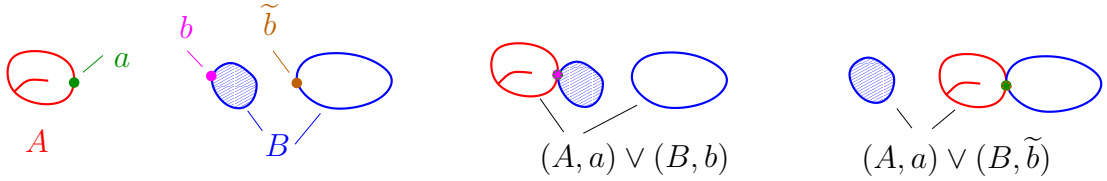
$$\begin{array}{rcl} \bigvee_{i\in I} f_i \colon \bigvee_{i\in I}(X_i, x_i) & \to & Z \\ [y] & \mapsto & f_i([y]) \text{ if } y \in X_i. \end{array}$$

It follows from the Topological-Quotient Proposition 5.15 (1b) that this map is indeed continuous.

(3) If $i = \{i_1, \dots, i_k\}$ is a finite family, then often we just write $(X_{i_1}, x_{i_1}) \vee \cdots \vee (X_{i_k}, x_{i_k})$ and similarly we just write $f_{i_1} \vee \cdots \vee f_{i_k}$.

Examples.

(1) The wedge $(A, a) \vee (B, b)$ of two pointed topological spaces (A, a) and (B, b) should be viewed as the result of gluing A and B along the points a and b.



(2) Let $n \in \mathbb{N}_0$ and let $G = (V = \{v\}, E, i, t)$ be an abstract graph with a *single* vertex. It follows quite easily from the Twice Quotient Lemma 5.23 (1) together with the fact that $[0, 1]/0 \sim 1$ is homeomorphic to S^1 that the map

$$\begin{array}{rcl} |G| = (V \sqcup (E \times [0,1]))/\sim & \to & \bigvee_{e\in E} S^1_e \\ [x] & \mapsto & \begin{cases} *, & \text{if } x = v, \\ \exp(2\pi \mathrm{i} t) \in S^1_e, & \text{if } x = (e,t) \in E \times [0,1] \end{cases} \end{array}$$

is a homeomorphism. Evidently this also shows that every topological graph with one vertex and n edges is homeomorphic to the wedge of n circles.

(3) In general the homeomorphism type of the wedge depends on the choice of base points. This becomes particularly clear if we consider disconnected spaces. For example it is pretty clear that the wedges $(A, a) \vee (B, b)$ and $(A, a) \vee (B, \widetilde{b})$ considered in the figure below are not homeomorphic.

Even though we just saw that in general the homeomorphism type of the wedge of two topological spaces depends on the choice of the base points, there are also many other situations where the choice is basically irrelevant. For example we have the following lemma.

Lemma 50.9. Let $\{X_i\}_{i\in I}$ be a family of smooth manifolds. We suppose that for each $i \in I$ we are given points $x_i, y_i \in X_i \setminus \partial X_i$. If each X_i is connected, then there exists a homeomorphism

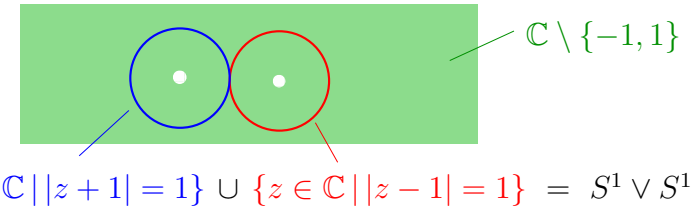
$$\bigvee_{i\in I}(X_i, x_i) \xrightarrow{\cong} \bigvee_{i\in I}(X_i, y_i).$$

Proof. The lemma is an almost immediate consequence of Proposition 36.4. We leave it to the reader to fill in the details. ■

This leads us to the following convention which is often safe, but which can also be ambiguous.

Convention. Let $\{X_i\}_{i\in I}$ be a family of non-empty topological spaces. For each $i \in I$ we pick a point $x_i \in X_i$ and we write

$$\bigvee_{i\in I} X_i \;:=\; \bigvee_{i\in I} (X_i, x_i).$$



Examples.

(1) On numerous occasions we will talk about the wedge $S^1 \vee S^1$ of two circles. By Lemma 50.9 there is usually no need to specify which points in the two copies of S^1 get identified.

(2) In Exercise 50.2 we will see that the wedge of two circles is homotopy equivalent to $\mathbb{C} \setminus \{\pm 1\}$. More precisely, we will show that

$$S^1 \vee S^1 \;=\; \underbrace{\{z \in \mathbb{C} \,|\, |z+1| = 1\} \cup \{z \in \mathbb{C} \,|\, |z-1| = 1\}}_{\text{two circles that meet at the origin}}$$

is a deformation retract of $\mathbb{C} \setminus \{\pm 1\}$.

Definition. Let $\{(X_j, x_j)\}_{j\in J}$ be a family of pointed topological spaces. Given $k \in J$ we refer to the maps

$$\begin{aligned} i_k \colon X_k &\to \bigvee_{j\in J} X_j \\ x &\mapsto [x] \end{aligned} \qquad \text{and} \qquad \begin{aligned} p_k \colon \bigvee_{j\in J} X_j &\to X_k \\ [x] &\mapsto \begin{cases} x, & \text{if } x \in X_k, \\ x_k, & \text{otherwise} \end{cases} \end{aligned}$$

as the natural inclusion respectively the natural projection.

Lemma 50.10. Let $\{X_j\}_{j\in J}$ be a family of topological spaces and suppose that for each $j \in J$ we are given a point $x_j \in X_j$. Let $k \in J$.

(1) The natural inclusion i_k is an embedding.

(2) A map $f \colon \bigvee_{j\in J} X_j \to Y$ to a topological space is continuous if and only if for each $k \in J$ the map $f \circ i_k \colon X_k \to Y$ is continuous.

(3) The natural projection p_k is continuous.

Remark. In most cases Lemma 50.10 allows us to safely view each X_k as a subset of the wedge $\bigvee_{j\in J} X_j$.

Proof.

(2) This statement follows easily from the Topological-Coproduct Proposition 5.11 (1) and the Topological-Quotient Proposition 5.15 (1b).
(3) This is an immediate consequence of (2).
(1) It follows easily from the Topological-Coproduct Proposition 5.11 (1) and the Topological-Quotient Proposition 5.15 (1a) that the natural inclusion i_k is continuous. It is clear that the natural inclusion i_k is an injection. Evidently we have $p_k \circ i_k = \mathrm{id}_{X_k}$. Since the natural projection p_k is continuous we see that the natural inclusion i_k is indeed an embedding. ■

The following lemma collects a few basic properties of the wedge of topological spaces. It is entirely possible that later on we use the lemma without giving it credit.

Lemma 50.11. Let $\{(X_i, x_i)\}_{i\in I}$ be a family of pointed topological spaces.

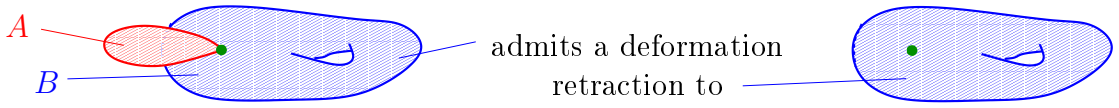
(1) If I is finite and if each X_i is compact, then $\bigvee_{i\in I} X_i$ is compact.
(2) If each X_i is Hausdorff, then $\bigvee_{i\in I} X_i$ is Hausdorff.
(3) If each X_i is (path)-connected, then $\bigvee_{i\in I} X_i$ is (path)-connected

Proof.

(1) It follows immediately from Lemma 50.10 (3) and the Topological-Coproduct Proposition 5.11 (1) that the map $\bigsqcup_{i\in I} p_i \colon \bigsqcup_{i\in I} X_i \to \bigvee_{i\in I} X_i$ is continuous. Thus the desired statement follows from the Disjoint Union Topology-Properties Lemma 5.13 (2) together with the Compact Image Lemma 2.13.
(2) We will prove this statement in Exercise 50.3.
(3) We will prove this statement in Exercise 50.4. ■

We conclude this section with two technical lemmas which can safely be skipped at a first reading.

Lemma 50.12. Let $\{(X_i, x_i)\}_{i\in I}$ be a family of pointed topological spaces and let (Z, z_0) be a pointed topological space. Furthermore let $\{f_i \colon (X_i, x_i) \to (Z, z_0)\}_{i\in I}$ and $\{g_i \colon (X_i, x_i) \to (Z, z_0)\}_{i\in I}$ be two families of maps. The following statement holds:



for every $i \in I$ there exists a homotopy rel x_i from f_i to g_i $\iff$ the maps $\bigvee_{i\in I} f_i$ and $\bigvee_{i\in I} g_i$ from $\bigvee_{i\in I} X_i$ to Z are homotopic rel the wedge point.

Proof. The "$\Leftarrow$"-direction of the lemma follows immediately from Lemma 50.10 (1). If the index set I has two elements, then the "$\Rightarrow$"-direction lemma is a straightforward consequence of the Homotopy Pushout Lemma 14.9 which eventually reduces the problem to the Product-Quotient Mixing Lemma 13.6. For a general family the "$\Rightarrow$"-direction lemma can also be reduced easily to the Product-Quotient Mixing Lemma 13.6.

It is worth pointing out that the proof of the "$\Rightarrow$"-direction is not obvious. As we just pointed out, it all boils down to the Product-Quotient Mixing Lemma 13.6. This lemma in turn relies on the delicate, frequently overlooked, underappreciated Whitehead Quotient Theorem 13.4. ■

The following lemma gives in particular a nice little application of Lemma 50.12.

Lemma 50.13. Let (A, a_0) and (B, b_0) be two pointed topological spaces. We consider the wedge $A \vee B = (A, a_0) \vee (B, b_0)$. If $\{a_0\}$ is a deformation retract of A, then $B = \{a_0\} \vee B$ is a deformation retract of $A \vee B$.

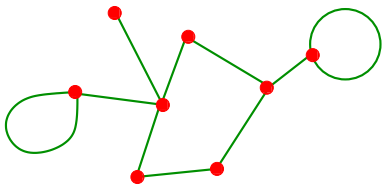
Proof. Let $F\colon A \times [0,1] \to A$ be a deformation retraction from A to $\{a_0\}$. Let G be the trivial homotopy on B. It follows again from the Homotopy Pushout Lemma 14.9 that we can combine the two homotopies to get the desired deformation retraction. ■

50.6. **Topological graphs.** In this section we have another look at abstract graphs and their topological incarnations. First we recall the following definitions from page 315.

Definition. Let $G = (V, E, i, t)$ be an abstract graph.

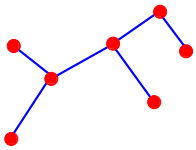
(1) If G is finite, i.e. if V and E are finite, then we refer to

$$\chi(G) \;=\; \#V \,-\, \#E \;=\; \text{number of vertices} \,-\, \text{number of edges}$$



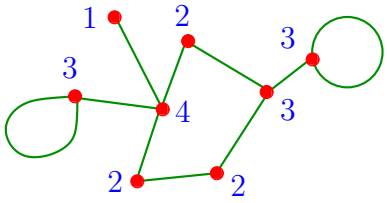
as the Euler characteristic of G.

(2) A tree is a finite connected abstract graph with Euler characteristic 1.



(3) The valence of a vertex v is defined as

$$\text{valence}(v) \;:=\; \#\{e \in E \,|\, i(e) = v\} + \#\{e \in E \,|\, t(e) = v\}.$$



Given a topological graph $(X, G = (V, E, i, t), \Theta\colon |G| \to X)$ we define the properties of X to be the properties of G, e.g. we define $\chi(X) := \chi(G)$ and we say that X is a tree if G is a tree.[525]

Euler characteristic of G
equals $\chi(G) = 8 - 10 = -2$

example of a tree

valences of the vertices

Proposition 50.14. Let T be a topological graph that is a tree. Then the following hold:

(1) If T has at least one edge, then it admits at least two vertices of valence one.

(2) The tree T admits a deformation retraction to a vertex, in particular it is contractible.

(3) The fundamental group $\pi_1(T)$ is trivial.

Remark. Proposition 50.14 is basically the constant of Exercise 15.6.

[525] On many occasions we will use the fact, established in the Abstract Graph-Topological Realization Lemma 7.1 (5), that a topological graph is connected if and only if the underlying abstract graph is connected.

Proof. Basically by definition of a topological graph it suffices to deal throughout with the topological realizations of a tree. Thus let $T = (V, E, i, t)$ be a tree.

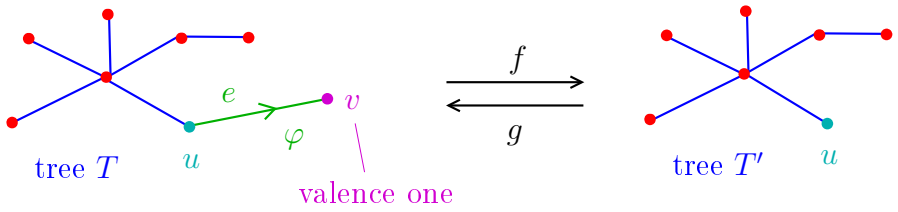
(1) This statement is precisely the content of Lemma 7.7.

(2) We will prove that any tree admits a deformation retraction to a vertex. We will prove this statement by induction on the number of edges. If a tree has zero edges, then it follows from the connectedness of T that T consists of precisely one vertex. So we are done.

Now suppose that we know that all trees with n edges admit a deformation retraction to a vertex. Let $T = (V, E, i, t)$ be a tree with $n+1$ edges. By (1) we know that T admits a vertex v of valence one. We denote by e the unique edge with v as an endpoint. We set $T' = (V \setminus \{v\}, E \setminus \{e\}, i|_{E\setminus\{e\}}, j|_{E\setminus\{e\}})$. Note that T' is again an abstract graph. Furthermore note that we reduced the number of vertices and of edges by one, so the Euler characteristic is unchanged, i.e. $\chi(T') = \chi(T) = 1$, so T' is again a tree.

We will now show that $|T'|$ is a deformation retract of $|T|$. We denote by u the other endpoint of e. We consider the maps

$$f\colon |T| \to |T'| \qquad x \mapsto \begin{cases} u, & \text{if } x \in |e|, \\ x, & \text{otherwise} \end{cases} \qquad \text{and} \qquad g\colon |T'| \to |T| \qquad x \mapsto x.$$



It follows quite easily from the Twice Quotient Lemma 5.23 (2) together with the Topological-Coproduct Proposition 5.11 that both maps are continuous.

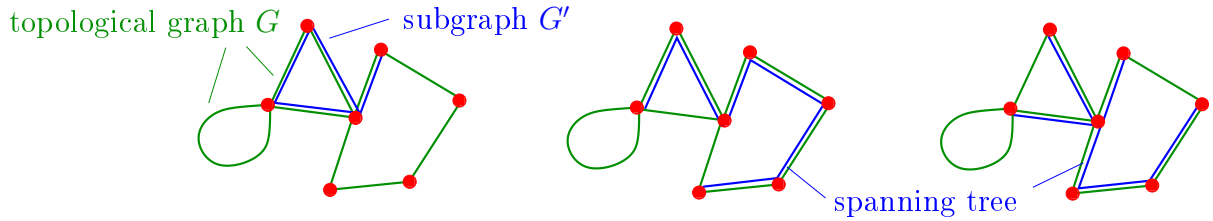
We claim that g is a homotopy inverse to f. Evidently $f \circ g = \mathrm{id}_{|T'|}$. We need to show that $g \circ f \simeq \mathrm{id}_{|T|}$. By definition and by the Abstract Graph-Topological Realization Lemma 7.1 (3) we can pick a characteristic map $\Phi_e\colon [0,1] \to |e|$ with $\Phi_e(0) = u$ and $\Phi_e(1) = v$. Next we consider the map

$$H\colon |T| \times [0,1] \to |T| \qquad (x,t) \mapsto \begin{cases} \Phi_e(\Phi_e^{-1}(x) \cdot t), & \text{if } x \in |e|, \\ x, & \text{otherwise.} \end{cases}$$

We leave it to the reader to verify, say using the Homotopy Quotient Theorem 14.7, Lemma 5.23 (2) and the Topological-Coproduct Proposition 5.11 that H is continuous. Now it is clear that H is a homotopy from $g \circ f$ to id_T.

We have thus shown that $|T'|$ is a deformation retract of $|T'|$. By our induction hypothesis $|T'|$ admits a deformation retraction to a vertex $v \in T'$. So it follows from the Homotopy Combination the Homotopy Combination Lemma 14.4 that $|T|$ also admits a deformation retraction to the vertex v. Finally it follows from this fact together with the Point Deformation Retract Lemma 15.6 (1) that T is contractible.

(3) It follows from (2) and the Homotopy-π_1-Proposition 50.3 (3) that the fundamental group of T is trivial. ■



Next we recall a few more definitions from page 317.

Definition. Let $G = (V, E, i, t)$ be an abstract graph.

(1) A subgraph of $G = (V, E, i, t)$ is an abstract graph $G' = (V', E', i', t')$ such that $V' \subset V$ and $E' \subset E$ are subsets such that $i' = i|_{E'}$ and $t' = t|_{E'}$.

(2) A spanning tree for G is a subgraph that is a tree and which does not admit an adjacent edge.

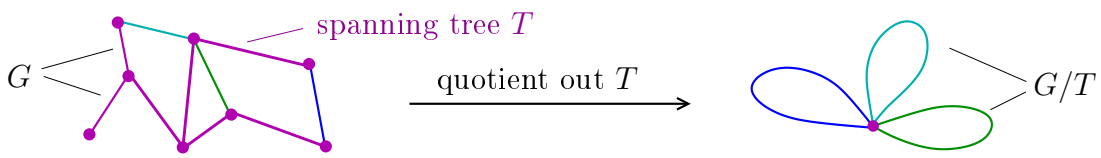
We extend the above definitions in an obvious way to topological graphs.

We conclude this discussion of abstract and topological graphs with the following proposition.

Proposition 50.15. Let $(X, G = (V, E, i, t), \Theta\colon |G| \to X)$ be a finite topological graph.

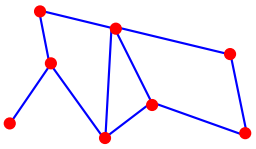
(1) For every spanning tree T of X the projection $X \to X/T$ is a homotopy equivalence.

(2) If X is connected and non-empty, then the topological graph X is homotopy equivalent to the wedge of $1 - \chi(X)$ circles.



(3) Two finite connected topological graphs with the same Euler characteristic are homotopy equivalent.

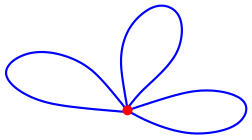
Remark.



(1) The content of Proposition 50.15 is basically identical to the content of the Graph-mod-Tree Proposition 17.10. WE will now give a somewhat different self-contained proof.

(2) In the Quotient-by-Tree Proposition 69.8 and the Quotient-by-Contractible Corollary 70.3 we will provide generalizations of Proposition 50.15.

(3) Later, in the Fundamental Group-of-Graph Proposition 52.5 we will study the question, whether the converse to Statement (3) holds: if two finite connected topological graphs are homotopy equivalent, does it follow that the Euler characteristics are the same?



Proof. As we mentioned above, the content of Proposition 50.15 is basically identical to the content of the Graph-mod-Tree Proposition 17.10. The proof of the Graph-mod-Tree Proposition 17.10 relied on the language of cofibrations and, more seriously, on the Homotopy Extension Theorem 70.1. We will now give a self-contained proof.

topological graph of Euler characteristic $8 - 10 = -2$

is homotopy equivalent to

wedge of three circles

First note that basically by definition we only need to deal with the topological realization of an abstract graph. Thus let $G = (V, E, i, t)$ be a finite connected abstract graph.

(1) Let $T = (W, F)$ be a spanning tree of G. Recall that on page 321 we introduced the notion of the quotient abstract graph G/T. Next we consider the following little commutative diagram

$$\begin{array}{ccc} |G| & \xrightarrow{\quad p \quad} & |G/T| \\ & {\scriptstyle x\mapsto[x]}\searrow \quad \nearrow & \\ & |G|/|T| & \end{array}$$

where p is the map introduced in the Quotient Abstract Graph Lemma 7.14 (2). We need to show that the projection $|G| \to |G|/|T|$ to the left is a homotopy equivalence. By the Quotient Abstract Graph Lemma 7.14 (2b) we know that the diagonal map to the right is a homeomorphism. Thus it suffices to show that the horizontal map $p\colon |G| \to |G/T|$ is a homotopy equivalence.

Note that by Proposition 50.14 (2) we know that $|T|$ admits a deformation retraction $R\colon |T| \times [0,1] \to |T|$ to some vertex $t_0 \in T$. Put differently, there exists a homotopy $R\colon |T| \times [0,1] \to |T|$ such that $R_1 = \mathrm{id}_{|T|}$ and such that $R_0 = c_{t_0}$ is the constant map.

Let f be an edge of G that is not contained in T. If $i(f) = t(f)$, then it follows from the Abstract Graph-Topological Realization Lemma 7.1 that there exists a map $\Phi_f\colon [-2,2] \to |G|$ which induces a homeomorphism $[-2,2]/-2 \sim 2 \to |f|$. Furthermore, if $i(f) \neq t(f)$, then it follows from the Abstract Graph-Topological Realization Lemma 7.1 that there exists a map $\Phi_f\colon [-2,2] \to |G|$ which restricts to a homeomorphism $[-2,2] \to |f|$.[526] We write $a_f = \Phi_f(-2)$ and $b_f = \Phi_f(2)$. Note that it follows from our hypothesis that T is a spanning tree together with the Spanning Tree Existence Proposition 7.10 that $a_f, b_f \in |T|$.

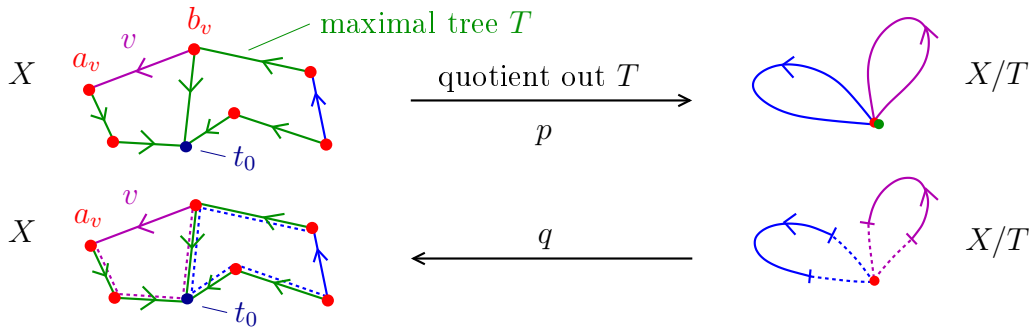
Next we consider the quotient graph G/T. Let $p\colon |G| \to |G/T|$ be the projection. For every edge f of G/T, i.e. for every $f \in E \setminus F$, we denote by $\Psi_f\colon [-2,2] \to |G/T|$ the map $p \circ \Phi_f$. We consider the map

$$\begin{array}{rcl} q\colon |G/T| & \to & |G| \\ x & \mapsto & \begin{cases} R(a_f, -s-1), & \text{if } x = \Psi_f(s) \text{ for some } s \in [-2,-1], \\ \Psi_f(2 \cdot s), & \text{if } x = \Psi_f(s) \text{ for some } s \in [-1,1], \\ R(b_f, s-1), & \text{if } x = \Psi_f(s) \text{ for some } s \in [1,2]. \end{cases} \end{array}$$

[526] In other words, the map Φ_f is just a rescaling of characteristic maps of f.

It follows fairly easily from the Twice Quotient Lemma 5.23 that q is continuous. (The maps p and q are illustrated, to the best of the author's abilities, in the figure below.) It remains to prove the following claim.

Claim. The maps p and q are homotopy inverses of one another.



Proof. The proof of the claim is fairly elementary, just notationally a little messy. First we consider the following map

$$H\colon |G/T| \times [0,1] \to |G/T|$$
$$(x,t) \mapsto \begin{cases} *, & \text{if } x = \Psi_f(s) \text{ for some } s \in [-2,-1-t], \\ \Psi_f(\frac{2s}{1+t}), & \text{if } x = \Psi_f(s) \text{ for some } s \in [-1-t,1+t], \\ *, & \text{if } x = \Psi_f(s) \text{ for some } s \in [1+t,2]. \end{cases}$$

It follows, reasonably easily, from the combination of the Twice Quotient Lemma 5.23 and the Homotopy Quotient Theorem 14.7 that H is continuous. It follows immediately from the definitions that $H_0 = p \circ q$ and $H_1 = \mathrm{id}_{|G/T|}$. Next we consider the following map

$$\widetilde{H}\colon |G| \times [0,1] \to |G|$$
$$(x,t) \mapsto \begin{cases} R(x,t), & \text{if } x \in T, \\ R(a_f, s+2+t), & \text{if } x = \Phi_f(s) \text{ for some } s \in [-2,-1-t], \\ \Phi_f(\frac{2s}{1+t}), & \text{if } x = \Phi_f(s) \text{ for some } s \in [-1-t,1+t], \\ R(b_f, -s+2+t), & \text{if } x = \Phi_f(s) \text{ for some } s \in [1+t,2]. \end{cases}$$

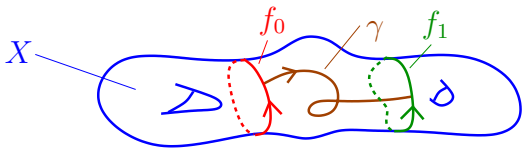
Again, using the Twice Quotient Lemma 5.23 and the Homotopy Quotient Theorem 14.7 one can show that $\widetilde{H}$ is continuous. Furthermore it follows again immediately from the definitions that $\widetilde{H}_0 = q \circ p$ and $\widetilde{H}_1 = \mathrm{id}_{|G|}$. ⊞

(2) Note that by the Spanning Tree Existence Proposition 7.10 (1) we know that G admits a spanning tree T. Furthermore note that in (1) we showed that the map $p\colon |G| \to |G/T|$ is a homotopy equivalence. Thus it remains to show that $|G/T|$ is homeomorphic to the wedge of $1-\chi(G)$ circles. We make the following observation:
   (a) By the Spanning Tree Existence Proposition 7.10 the spanning tree T contains all vertices of G. In other words, the abstract graph G/T contains only a single vertex.
   (b) It follows from the Quotient Abstract Graph Lemma 7.14 (2) and the definition of a tree in terms of the Euler characteristic that $\chi(G/T) = \chi(G) - \chi(T) + 1 = \chi(G)$.
   (c) By (1) and (2) we know that G/T has $1-\chi(G)$ edges.

(d) It follows from (1) and (3), together with the discussion on page 1133 that $|G/T|$ is indeed homeomorphic to the wedge of $1-\chi(G)$ circles.

(3) The last statement is an immediate consequence of (2) and the Homotopy-Equivalence Basics Lemma 15.1. ■

50.7. **Homotopy classes of loops.** In the last section of this chapter we want to study the question, when are two maps $S^1 \to X$ to a topological space homotopic? In fact the following proposition gives in some sense a complete answer to the above question.

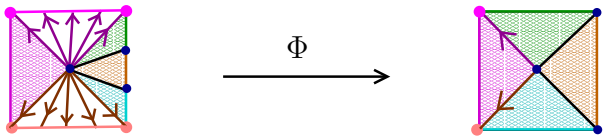


Proposition 50.16. (Homotopies-of-Loops Proposition) Let X be a topological space and let $f_0, f_1 \colon S^1 \to X$ be two maps. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$.

(1) The following statement holds:[527]

$$f_0 \text{ and } f_1 \text{ are homotopic} \iff \begin{array}{c}\text{there exists a path } \gamma \text{ from } x_0 \text{ to } x_1 \\ \text{such that } [\gamma * f_1 * \overline{\gamma}] = [f_0] \in \pi_1(X, x_0).\end{array}$$

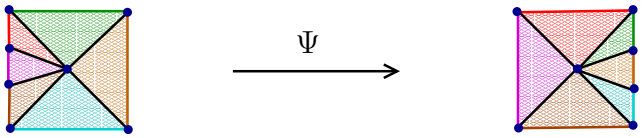
(2) If $x_0 = x_1$, then the following statement holds:



$$f_0 \text{ and } f_1 \text{ are homotopic} \iff [f_0] \text{ and } [f_1] \text{ are conjugate in } \pi_1(X, x_0).$$

Proof. Note that the second statement is an immediate consequence of the first statement and the observation that if $x_0 = x_1$ any path from x_0 to $x_1 = x_0$ is in fact a loop and thus defines an element in $\pi_1(X, x_0)$. Therefore it suffices to prove the first statement.

Now let X be a topological space. We take the view that maps $S^1 \to X$ are the same as loops, i.e. maps $[0,1] \to X$ such that 0 and 1 get sent to the same point. Thus let $f_0, f_1 \colon [0,1] \to X$ be two loops. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$.



"$\Rightarrow$" Suppose there exists a homotopy $F \colon [0,1] \times [0,1] \to X$ with $F(0,t) = F(1,t)$ for all $t \in [0,1]$ and such that $F_0 = f_0$ and $F_1 = f_1$. We denote by $\gamma \colon [0,1] \to X$ the path that is given by $\gamma(t) = F(0,t)$ for $t \in [0,1]$. We consider the surjective map $\Phi \colon [0,1] \times [0,1] \to [0,1] \times [0,1]$ that is shown in the figure below. The map $\Phi \circ F$ is easily seen to be a homotopy between the loops f_0 and $\gamma * f_1 * \overline{\gamma}$. But that is exactly what we needed to show.

"$\Leftarrow$" In the following we now suppose that there exists a path γ from x_0 to x_1 such that $[\gamma * f_1 * \overline{\gamma}] = [f_0] \in \pi_1(X, x_0)$. By definition this means that there exists a homotopy $F \colon [0,1] \times [0,1] \to X$ with $F(0,t) = F(1,t) = x_0$ for all $t \in [0,1]$ and such that $F_0 = f_0$ and $F_1 = \gamma * f_1 * \overline{\gamma}$. We consider the homeomorphism $\Psi \colon [0,1] \times [0,1] \to [0,1] \times [0,1]$ that is shown in the figure below. The map $\Psi \circ F$ is easily seen to be a homotopy

[527] Sometimes two maps $S^1 \to X$ that are homotopic are called *freely homotopic* to stress the fact that no base points are fixed.

between $c_{x_0} * f_0 * c_{x_0}$ and f_1, viewed as maps $S^1 \to X$. But the map $c_{x_0} * f_0 * c_{x_0}$ is easily seen to be homotopic to the map f_0. Since being homotopic is transitive we have indeed shown that f_0 and f_1 are homotopic.

■

Exercises for Chapter 50.

Exercise 50.1. Let $n \in \mathbb{N}$.

(a) Show that $\mathrm{SL}(n, \mathbb{R})$ is a retract of $\mathrm{GL}(n, \mathbb{R})$ and show that it is not a deformation retract of $\mathrm{GL}(n, \mathbb{R})$.

(b) Solve (a) with $\mathbb{C}$ instead of $\mathbb{R}$.

Exercise 50.2. Show that

$$S^1 \vee S^1 \;=\; \underbrace{\{z \in \mathbb{C} \,|\, |z+1| = 1\} \cup \{z \in \mathbb{C} \,|\, |z-1| = 1\}}_{\text{two circles that meet at the origin}}$$

is a deformation retract of $\mathbb{C} \setminus \{\pm 1\}$.

Exercise 50.3. Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces. We suppose that each X_i is Hausdorff. Show that $\bigvee\limits_{i \in I} X_i$ is also Hausdorff.

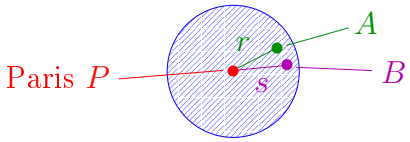
Exercise 50.4. Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces.

(a) We suppose that each X_i is path-connected. Show that $\bigvee\limits_{i \in I} X_i$ is path-connected.

(b) We suppose that each X_i is connected. Show that $\bigvee\limits_{i \in I} X_i$ is connected.

Exercise 50.5. Let $X := \{(x, y) \in \mathbb{R}^2 \,|\, x^2 + y^2 \leq 1\}$. We denote by $\| - \|$ the usual Euclidean norm on X. We denote by $P = (0, 0)$ the center of X. The *Paris metric* on X is given by

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} \\ (A, B) & \mapsto & \|A - P\| + \|B - P\|. \end{array}$$



This metric takes its name from the fact that all (OK, many) train lines in France go towards Paris. So if you want to go from A to B you invariably (OK, often) have to go through Paris.

(a) Show that the map

$$\begin{array}{rcccl} \varphi\colon \bigvee\limits_{z \in S^1} [0,1]_z & \to & X & & \\ [r] & \mapsto & r \cdot z & \text{if } r \in [0,1]_z. & \end{array}$$

is not a homeomorphism.

(b) Does there exist a homeomorphism between $\bigvee\limits_{z \in S^1} [0,1]_z$ and X?

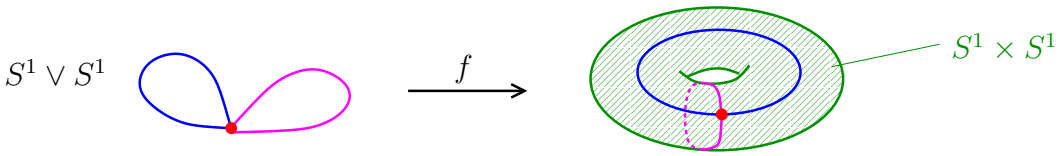
in the Paris metric the distance between P and Q equals $r+s$

Exercise 50.6. Let (X,x_0) and (Y,y_0) be two pointed topological spaces. We use the base points to define the wedge $X \vee Y$.

(a) Show that the map

$$\begin{array}{rcl} f\colon X \vee Y & \to & X \times Y \\ [P] & \mapsto & \begin{cases} (P,y_0), & \text{if } P \in X, \\ (x_0,P), & \text{if } P \in Y \end{cases} \end{array}$$

is an embedding.



Remark. We do not assume that X and Y have any nice properties.

(b) Using (a) we can view $X \vee Y$ as a subspace of $X \times Y$. We refer to the quotient

$$X \wedge Y \;:=\; (X,x_0) \wedge (Y,y_0) \;:=\; (X \times Y)/(X \vee Y)$$

as the *smash product of* (X,x_0) *and* (Y,y_0). Show that for any $m,n \in \mathbb{N}_0$ the smash product $S^m \wedge S^n$ is homeomorphic to S^{m+n}.

We refer to the figure below for an illustration.

Exercise 50.7. We consider the following two subsets of $\mathbb{C}$:

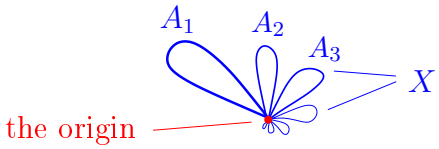
$$\begin{aligned} X &:= \underbrace{\{z \in \mathbb{C} \,|\, |z-2|=1\}}_{=:A} \cup [-1,1] \cup \underbrace{\{z \in \mathbb{C} \,|\, |z+2|=1\}}_{=:B} \quad \text{and} \\ Y &:= \underbrace{\{z \in \mathbb{C} \,|\, |z-1|=1\}}_{=:C} \cup \underbrace{\{z \in \mathbb{C} \,|\, |z+1|=1\}}_{=:D}. \end{aligned}$$

Show that X and Y are homotopy equivalent.

Remark. It follows basically from Proposition 50.15 that X and Y are homotopy equivalent. The exercise thus consists of showing "by hand" that X and Y are homotopy equivalent.

Exercise 50.8. Let $\{X_i\}_{i \in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a point $x_i \in X_i$ with the property that $\{x_i\}$ is a closed subset of X_i. We use these points to form the wedge $\bigvee\limits_{i \in I} X_i$. We denote by $*$ the wedge point. Suppose that for each $i \in I$ we are given an open neighborhood U_i of x_i in X_i such that x_i is a deformation retract of U_i. We set $U := \bigcup\limits_{i \in I} U_i$.

(a) Show that U is an open neighborhood of $*$.



(b) Let $J \subset I$ be a subset. Show that $\bigvee_{i \in J} X_i$ is a deformation retract of $U \cup \bigvee_{i \in J} X_i$. (In particular, with $J = \varnothing$ this implies that $*$ is a deformation retract of U.)
Remark. You need to show that the wannabe deformation retraction which you wrote down is continuous. You might want to use a result along the lines of the Product-Quotient Mixing Lemma 13.6.

Exercise 50.9. Let $\{X_i\}_{i \in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a point $x_i \in X_i$. We use these points to form the wedge $\bigvee_{i \in I} X_i$. Let $K \subset \bigvee_{i \in I} X_i$ be a compact subset.

(a) We suppose that each X_i is Hausdorff. Show that there exists a finite subset $J \subset I$ such that $K \subset \bigvee_{i \in J} X_i$.
Hint. For any $i \in I$ with $K \cap (X_i \setminus \{x_i\}) \neq \varnothing$ pick some point $a_i \in K \cap (X_i \setminus \{x_i\})$. We denote by A the union of these points. Show that A is a discrete subset of K.
(b) Show that in general the conclusion of (a) does not hold if we do not assume that the X_i are Hausdorff.

Exercise 50.10. We consider the subset X of $\mathbb{R}^2$ that is shown in the figure below. It is the union of infinitely many circles $A_i \subset \mathbb{R}^2$, $i \in \mathbb{N}$ that meet in the origin. Furthermore let $Y = \bigvee_{i \in \mathbb{N}} S^1$. There exists a fairly obvious bijection $f\colon X \to Y$ which sends each A_i to the i-th factor of Y.

(a) Is the map f continuous?
(b) Is the map f^{-1} continuous?

Exercise 50.11. In the following we consider the wedge $X := \bigvee_{i \in \mathbb{N}_0} [0,1]_i$ given by "wedging" the points $0 \in [0,1]_i$, $i \in \mathbb{N}_0$.

(a) Show that the sequences of points $x_i := \frac{1}{2^i} \in [0,1]_i \subset X$, $i \in \mathbb{N}_0$ does not converge to the wedge point.
(b) Show that X is not metrizable, i.e. show that it does not admit a metric such that the topology given by the metric agrees with the topology of X.

Exercise 50.12. Let $f, g\colon (X, x_0) \to (Y, y_0)$ be two maps between pointed topological spaces.

(a) Show that if f and g are homotopic rel $\{x_0\}$, then $f_* = g_*\colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$.
(b) Does the conclusion of (a) hold if we only demand that f and g are homotopic, but we no longer demand that they are homotopic rel the base point?

Exercise 50.13. Let $f\colon X \to Y$ be a map between two topological spaces. Let $x_0 \in X$ be a base point. We write $y_0 = f(x_0)$ and we denote by $i\colon f(X) \to Y$ the inclusion map. Suppose that $f_*\colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$ is an isomorphism. Does it follow that $i_*\colon \pi_1(f(X), y_0) \to \pi_1(Y, y_0)$ is also an isomorphism?

Exercise 50.14.

(a) Show that every topological graph is locally contractible.
(b) Let $\{(X_i, x_i)\}_{i\in I}$ be a family of pointed topological spaces. We suppose that each X_i is locally contractible. Show that the wedge $\bigvee_{i\in I} X_i$ is also locally contractible.

Remark. If you get away without using the Homotopy Quotient Theorem 14.7, then you should go carefully over your continuity arguments.

Exercise 50.15. Let T be a tree and let $v \in T$ be any vertex. Show that T admits a deformation retraction to v.
Remark. This is a slight refinement of the statement of Proposition 50.14 (2).

Exercise 50.16. Let N be a group, let $k \in \mathbb{N}_0$ and let $\varphi\colon N \to N$ be an isomorphism such that $\varphi^k = \mathrm{id}$. As on page 1127 we define the *semidirect product of N and $\mathbb{Z}_k$ with respect to φ* as the group $N \rtimes_\varphi \mathbb{Z}_k$ where the underlying set is given by the direct product $N \times \mathbb{Z}_k$, and where the multiplication is given by

$$(h, m) \cdot (h', m') := (h \cdot \varphi^m(h'), m + m').$$

(a) Show that $N \rtimes_\varphi \mathbb{Z}_k$ is indeed a group.
(b) Show that $N = \{(h, 0) \in N \rtimes_\varphi \mathbb{Z}_k \,|\, h \in N\}$ is a normal subgroup of $N \rtimes \mathbb{Z}_k$.
(c) Is $\mathbb{Z}_k = \{(0, n) \in N \rtimes_\varphi \mathbb{Z}_k \,|\, n \in \mathbb{Z}_k\} \subset N \rtimes_\varphi \mathbb{Z}_k$ necessarily a normal subgroup?
(d) Suppose that $k = 0$. Let $n \in \mathbb{N}$ and let K be a subgroup of N of some finite index m. Show that if K is preserved by φ, then $K \rtimes n\mathbb{Z}$ is a subgroup of $N \rtimes \mathbb{Z}$ of index $m \cdot n$.

Exercise 50.17. Let N be a group and let $\varphi\colon N \to N$ be an isomorphism.

(a) Let $k \in \mathbb{N}$ and let $G \subset N$ be a subgroup with $\varphi^k(G) = G$. Show that $k\mathbb{Z} \rtimes_\varphi G$ is a subgroup of $\mathbb{Z} \rtimes_\varphi N$.
(b) Show that in general not every subgroup of $\mathbb{Z} \rtimes_\varphi N$ is of the form $k\mathbb{Z} \rtimes_\varphi G$.
(c) Let π be a finite-index subgroup of $\mathbb{Z} \rtimes_\varphi N$.
  (i) Show that there exists a $k \in \mathbb{N}$ and a normal subgroup G of N with $\varphi^k(G) = G$ such that $[\mathbb{Z} \rtimes_\varphi N : \pi] = k \cdot [G : \pi]$ and such that π is *isomorphic* to $\mathbb{Z} \rtimes_{\varphi^k} G$.
  (ii) We suppose that N is finitely generated. Show that there exists a $k \in \mathbb{N}$ and a normal finite-index subgroup G of N such that $k\mathbb{Z} \rtimes_\varphi G \subset \pi$.

Exercise 50.18. Let

$$\begin{array}{ccccccccc}
1 & \longrightarrow & K & \xrightarrow{\varphi} & \pi & \xrightarrow{\psi} & G & \longrightarrow & 1 \\
 & & \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \beta} & & \downarrow{\scriptstyle \gamma} & & \\
1 & \longrightarrow & \widetilde{K} & \xrightarrow{\widetilde{\varphi}} & \widetilde{\pi} & \xrightarrow{\widetilde{\psi}} & \widetilde{G} & \longrightarrow & 1
\end{array}$$

be a commutative diagram of group homomorphisms with the following properties:

(1) φ and $\widetilde{\varphi}$ are monomorphisms.
(2) ψ and $\widetilde{\psi}$ are epimorphisms.
(3) $\mathrm{im}(\varphi) = \ker(\psi)$ and $\mathrm{im}(\widetilde{\varphi}) = \ker(\widetilde{\psi})$.

Show that if two out of the three vertical maps α, β and γ are isomorphisms, then so is the third one.
Remark. We will generalize this statement later on in the Five Lemma 74.10.

Exercise 50.19. Let π be a group and let $\phi\colon \pi \times \langle t\rangle \to \mathbb{Z}$ be an epimorphism. We suppose that $k := \phi(t) \neq 0$. We set $\Gamma := \ker(\pi \xrightarrow{\phi} \mathbb{Z} \to \mathbb{Z}_k)$. Since ϕ is an epimorphism there exists an $x \in \pi$ such that $\gcd(\phi(x), k) = 1$. Let $\mu\colon \Gamma \to \Gamma$ be the automorphism that is given by $g \mapsto xgx^{-1}$. Show that the map

$$\begin{array}{rcl} \Gamma \rtimes_\mu \mathbb{Z} & \to & \pi \times \mathbb{Z} \\ (g, n) & \mapsto & (gx^n, n + \phi(g)) \end{array}$$

is an isomorphism.
Hint. You could use Exercise 50.18 together with Exercise 50.16 (d).
Remark.

(1) By Exercise 53.2 and Proposition 69.15 we know that if π is finitely generated (presented), then so is Γ. The exercise thus says that if a finitely presented group π admits an epimorphism onto $\mathbb{Z}$, then we can write a product $\pi \times \mathbb{Z}$ in many interesting and perhaps surprising ways as a semidirect product.
(2) We will prove a manifold analogue in Proposition 118.15.

Exercise 50.20. Let G and π be groups and let $\varphi\colon \pi \to \mathrm{Aut}(G)$ be a homomorphism. We consider the set $G \times \pi$ with the multiplication

$$(g, a) \cdot (h, b) \;:=\; (g \cdot \varphi(a)(h), a \cdot b).$$

(a) Show that $G \times \pi$ with the above multiplication is a group. This group is denoted by $G \rtimes_\varphi \pi$ and it is called the *semidirect product of G and π with respect to φ*.
(b) In what sense does this definition of the semidirect product of two groups generalize the concept introduced on page 1127?
(c) Let K be a group and let $\alpha\colon K \to \pi$ be an epimorphism onto a group π. We suppose that α admits a right-inverse, i.e. we suppose that there exists a homomorphism $\varphi\colon \pi \to K$ with $\alpha \circ \varphi = \mathrm{id}_\pi$. Show that K is isomorphic to a semidirect product of the form $\ker(\alpha) \rtimes \pi$.
(d) (i) Let $n \in \mathbb{N}$. Show that $\mathrm{GL}(n, \mathbb{R})$ is isomorphic to a semidirect product of the form $\mathrm{SL}(n, \mathbb{R}) \rtimes (\mathbb{R} \setminus \{0\})$.
(ii) For which $n \in \mathbb{N}$ is $\mathrm{GL}(n, \mathbb{R})$ isomorphic to a direct product $\mathrm{SL}(n, \mathbb{R}) \rtimes (\mathbb{R} \setminus \{0\})$?
(iii) Repeat (i) and (ii) with $\mathbb{C}$ instead of $\mathbb{R}$.

51. Basics of group theory

Before we continue with developing the theory of fundamental groups of topological spaces we want to introduce several basic constructions in group theory and we want state several facts which we will use throughout the remainder of this course.

51.1. **Free abelian groups and finitely generated abelian groups.** The following definition will stay with us throughout these notes.

Definition.

(1) Let S be a non-empty set. We write

$$\mathbb{Z}^S \;:=\; \text{all maps from } S \text{ to } \mathbb{Z}.$$

Furthermore, for S the empty set we write $\mathbb{Z}^S := \{0\}$. We consider $\mathbb{Z}^S$ with the obvious group structure, i.e. the group structure that is given by

$$\begin{array}{ccc} \mathbb{Z}^S \times \mathbb{Z}^S & \to & \mathbb{Z}^S \\ (f,g) & \mapsto & \left(\begin{array}{ccc} S & \to & \mathbb{Z} \\ s & \mapsto & f(s)+g(s) \end{array} \right). \end{array}$$

(2) Given any set S, we are mostly interested in the subgroup

$$\mathbb{Z}^{(S)} \;:=\; \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S.$$

We refer to $\mathbb{Z}^{(S)}$ as the free abelian group generated by S or as the free abelian group on the generating set S.

(3) We refer to the cardinality of S as the rank of $\mathbb{Z}^{(S)}$.

When working with free abelian groups it is usually helpful to use the following notation.

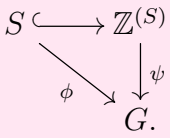
Notation. Let S be a set.

(1) Given $s \in S$ we denote by s also the map

$$\begin{array}{ccc} S & \to & \mathbb{Z} \\ t & \mapsto & \begin{cases} 1, & \text{if } t = s, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

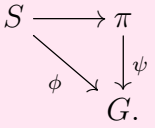
This map lies of course in $\mathbb{Z}^{(S)}$. Thus we can view S as a subset of $\mathbb{Z}^{(S)}$.

(2) Given elements $s_1, \ldots, s_k \in S$ and $n_1, \ldots, n_k \in \mathbb{Z}$ we obtain the corresponding element $n_1 s_1 + \cdots + n_k s_k$ of $\mathbb{Z}^{(S)}$. We refer to $n_1 s_1 + \cdots + n_k s_k$ as a formal linear combination of elements in S. Every element of $\mathbb{Z}^{(S)}$ can be written as such a formal linear combination of finitely many elements of S. Indeed, for $f \in \mathbb{Z}^{(S)}$ we can write[528]



$$f \;=\; \sum_{s \in S \text{ with } f(s) \neq 0} f(s) \cdot s.$$

The following lemma says that the free abelian group generated by a set S has a "universal property". The lemma also says that possessing such a universal property classifies free abelian groups up to isomorphism.



[528] It is straightforward to see that both sides define the same map $S \to \mathbb{Z}$, so they are the same element of $\mathbb{Z}^{(S)}$.

Lemma 51.1.

(1) Let S be a set and let $\phi\colon S \to G$ be a map to an abelian group G. Then there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(S)} \to G$ that makes the following diagram commute

(2) Conversely let π be a group that admits a subset S with the following universal property: given any map $\phi\colon S \to G$ to an abelian group G there exists a unique homomorphism $\psi\colon \pi \to G$ that makes the following diagram commute

Then π is isomorphic to $\mathbb{Z}^{(S)}$.

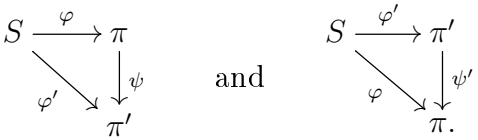
Lemma 51.1 suggests the following definition.

Definition.

(1) We say that a group π is a free abelian group on a generating set S, if π has the universal property with respect to S. In other words, by Lemma 51.1, G needs to be isomorphic to $\mathbb{Z}^{(S)}$.

(2) We say that a group π is free abelian if it is a free abelian group on some generating set S.

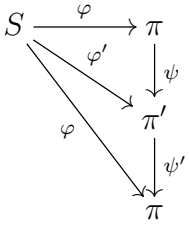
Proof.



(1) We consider the map[529]

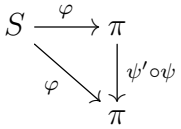
$$\begin{array}{rcl} \psi\colon \mathbb{Z}^{(S)} & \to & G \\ f = \sum_{i=1}^{n} n_i s_i & \mapsto & \psi(f) := \sum_{i=1}^{n} n_i \cdot \phi(s_i). \end{array}$$

It is straightforward to verify that ψ has the desired property and that it is the unique such homomorphism.

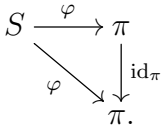


(2) Let π be a group that has the universal property with respect to S. We need to show that π is isomorphic to $\mathbb{Z}^{(S)}$. It is more elegant to show that it is isomorphic to any other group π' that has the universal property with respect to S.

This argument is similar to many other "universal property" proofs in algebra. We consider the inclusion maps $\varphi\colon S \to \pi$ and $\varphi'\colon S \to \pi'$. By the universal property of φ and φ' there exist homomorphisms $\psi\colon \pi \to \pi'$ and $\psi'\colon \pi' \to \pi$ that make the following diagrams commute:



[529]Here we assume that G is written as an additive group. If G is a multiplicative group we would need to replace $n_i \cdot \phi(s_i)$ by $\phi(s_i)^{n_i}$ and we would need to replace the sum by a product.



In particular we get the commutative diagrams

which simplifies to

and of course we also have the commutative diagram

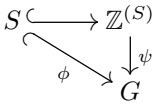
It follows from the uniqueness part of the universal property applied to the two diagrams on the right that $\psi' \circ \psi = \mathrm{id}_\pi$. The same way one shows that $\psi \circ \psi' = \mathrm{id}_{\pi'}$. In particular ψ and ψ' are isomorphisms. ■

Lemma 51.2. (Subgroup-of-Free Abelian Group Lemma)

(1) Any subgroup G of a free abelian group F is again a free abelian group.
(2) If $\varphi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ is a monomorphism, then[530] $\#S \leq \#T$.
(3) If $\varphi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ is an epimorphism, then $\#S \geq \#T$.

Proof. The first two statements are proved in [**Rot1988**, Theorem 9.3]. It remains to prove the third statement. Now let $\varphi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ be an epimorphism. For each $t \in T$ there exists therefore some $\phi(t) \in S$ with $\varphi(\phi(t)) = t$. By Lemma 51.1 there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(T)} \to \mathbb{Z}^{(S)}$ with $\psi(t) = \phi(t)$ for all $t \in T$. Therefore we have $\varphi(\psi(t)) = \varphi(\phi(t)) = t$ for all t, so $\varphi \circ \psi = \mathrm{id}$, in particular ψ is a monomorphism. It follows from (2) that $\#T \leq \#S$. ■

Definition.



(1) If F is a free abelian group, then we define the rank of F as the cardinality of any set S with $F \cong \mathbb{Z}^{(S)}$.[531]
(2) Given an abelian group G we say that $S \subset G$ is a generating set if the canonical homomorphism $\mathbb{Z}^{(S)} \to G$ is an epimorphism.[532]
(3) Given an abelian group G we say that $S \subset G$ is a basis if the canonical homomorphism $\mathbb{Z}^{(S)} \to G$ is an isomorphism.
(4) We say that an abelian group G is finitely generated if it admits a finite generating set.

Example. Let S be a finite set with m elements $s_1, \ldots, s_m$. Let $\phi\colon S \to \mathbb{Z}^m$ be the map given by $\phi(s_i) = e_i$. Then the resulting homomorphism $\Psi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^m$ is an isomorphism. Put differently, $\mathbb{Z}^m$ is a free abelian group of rank m.

[530] Here we denote by $\#S$ and $\#T$ the cardinalities of the sets S and T, as defined on page 94.

[531] It follows from the Subgroup-of-Free Abelian Group Lemma 51.2 and the Bernstein-Schröder Theorem 0.11 that the rank of a free abelian group is well-defined.

[532] Here we mean by "canonical map $\mathbb{Z}^{(S)} \to G$" the unique homomorphism $\psi\colon \mathbb{Z}^{(S)} \to G$ from Lemma 51.1 that makes the following diagram commute

where $S \to G$ is the inclusion map.

We leave it to the reader to provide the proof of the following useful characterizations of generating sets.

Lemma 51.3. Let G be an abelian group and let $S \subset G$ be a subset. Then the following two statements are equivalent:

(1) S is a generating set of G.
(2) Any subgroup H of G that contains S is already equal to G.

We use this opportunity to recall the classification of finitely generated abelian groups which had been proved in the algebra course. A proof is for example also provided in [**Hun1980**, Chapter II.2].

Theorem 51.4. (Finitely Generated Abelian Group Classification Theorem) Let A be a finitely generated abelian group. There exist non-zero natural numbers $a_1, \dots, a_k$ with $a_i | a_{i+1}$ for $i = 1, \dots, k-1$ and an $r \in \mathbb{N}_0$ such that

$$A \;\cong\; \mathbb{Z}^r \oplus \bigoplus_{i=1}^{k} \mathbb{Z}_{a_i}.$$

Furthermore the numbers $a_1, \dots, a_k$ and r are uniquely determined by A.

Definition. Given a finitely generated abelian group A we denote the direct sum of the cyclic groups on the right-hand side of the Finitely Generated Abelian Group Classification Theorem 51.4 as the canonical form of A.

Example. The Chinese Remainder Theorem says that for any coprime m and n we have an isomorphism

$$\begin{array}{rcl} \mathbb{Z}_{mn} & \xrightarrow{\cong} & \mathbb{Z}_m \times \mathbb{Z}_n = \mathbb{Z}_m \oplus \mathbb{Z}_n \\ k + mn\mathbb{Z} & \mapsto & (k + m\mathbb{Z}, k + n\mathbb{Z}). \end{array}$$

For example consider $A = \mathbb{Z}_3 \oplus \mathbb{Z}_5$. It is not in the form of the Finitely Generated Abelian Group Classification Theorem 51.4, but we have the isomorphism $\mathbb{Z}_3 \oplus \mathbb{Z}_5 \cong \mathbb{Z}_{15}$, which is of the desired form. Thus $\mathbb{Z}_{15}$ is the canonical form of $\mathbb{Z}_3 \oplus \mathbb{Z}_5$.

We will not provide a proof for the Finitely Generated Abelian Group Classification Theorem 51.4. But we will sketch the proof of a weaker version of the Classification Theorem 51.4. Before we can get to this point we need to prove the following theorem.

Theorem 51.5. (Smith Normal Form Theorem) Let V be an $m \times n$–matrix over $\mathbb{Z}$. There exist two matrices $A \in \mathrm{GL}(m, \mathbb{Z})$ and $B \in \mathrm{GL}(n, \mathbb{Z})$[533] such that[534]

$$A \cdot V \cdot B \;=\; \begin{pmatrix} p_1 & 0 & 0 & 0 \\ 0 & \ddots & 0 & 0 \\ 0 & 0 & p_t & 0 \\ 0 & 0 & 0 & 0_{(m-t)\times(n-t)} \end{pmatrix} \;\in\; \mathrm{M}(m \times n, \mathbb{Z})$$

for some $p_1, \dots, p_t \in \mathbb{N}$. The matrix on the right is sometimes called a Smith normal form of V.

[533] The matrices A and B are invertible over $\mathbb{Z}$, i.e. their determinants are ± 1.
[534] Here the last row and column of zeros can be arbitrarily large.

Remark. In Exercise 51.19 we will discuss a more refiend version of the Smiith Normal Form Theorem 51.5, which then also gives us a uniqueness statement for the Smith normal form. Alternativel we refer to [**NewM1972**, Chapter 15] and [**Nor2012**, Chapter 1] for more information.

Proof. First note that if an $m \times n$–matrix P is obtained from an $m \times n$–matrix Q by swapping two rows, then P is obtained by left-multiplying Q by an $m \times m$–matrix of the form[535]

$$\begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}.$$

Similarly if P is obtained from an $m \times n$–matrix Q by adding the k-th row to the l-th row, then P is obtained by left-multiplying Q by an $m \times m$–matrix of the form

$$\begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}$$

where the extra 1 sits in the $(1,k)$-entry. Both these $m \times m$-matrices lie in $\mathrm{GL}(m,\mathbb{Z})$. If we do the same operations for columns, then this corresponds to right multiplication by the same type of matrices in $\mathrm{GL}(n,\mathbb{Z})$ as above.

Now let V be an $m \times n$–matrix over $\mathbb{Z}$. If V is the zero matrix, then there is nothing to show. So suppose that V is not the zero matrix. We perform the following steps:

(1) After swapping rows and columns we can arrange that the absolute value of the $(1,1)$-entry is less or equal than the absolute value of all other entries. After possibly multiplying the first column by -1 we can assume that the $(1,1)$-entry v_{11} is positive.
(2) By adding and subtracting the first column from the other columns we can arrange that all entries in the first row, except for the $(1,1)$-entry, lie between 0 and $v_{11} - 1$.
(3) The same way as in (2) we can arrange that all entries in the first column, except for the $(1,1)$-entry, lie between 0 and $v_{11} - 1$.

Now we have to distinguish two cases:

(1) If there exists outside of the $(1,1)$-entry another entry in the first row or column that is non-zero, then we start again with (1). Note that the new entry $(1,1)$-entry will be less than before. So this process will come to a halt after finitely many steps.
(2) If all entries in the first row and column, except for the $(1,1)$-entry are zero, then

$$V = \begin{pmatrix} v_{11} & 0 \\ 0 & V' \end{pmatrix}$$

for some $(m-1) \times (n-1)$–matrix V' and we perform the same operations on the smaller matrix V'. ∎

[535] Here is the reality check whether that is really correct: we have

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} c & d \\ a & b \end{pmatrix}.$$

The second statement of the following lemma is a somewhat weaker version of Theorem 51.4.

Lemma 51.6. (Matrix Quotient Lemma)

(1) Let V be an $m \times n$–matrix over $\mathbb{Z}$. For matrices $A \in \mathrm{GL}(m, \mathbb{Z})$ and $B \in \mathrm{GL}(n, \mathbb{Z})$ we have an isomorphism

$$\mathbb{Z}^m / AVB\mathbb{Z}^n \;\cong\; \mathbb{Z}^m / V\mathbb{Z}^n.$$

(2) Let A be a finitely generated abelian group. Then there exists an $r \geq 0$ and there exist $p_1, \ldots, p_t \in \mathbb{N}$ such that

$$A \;\cong\; \mathbb{Z}^r \oplus \bigoplus_{i=1}^{t} \mathbb{Z}_{p_i}.$$

Proof. (1) The proof of the first statement is elementary. We leave it to the reader to fill in the details.

(2) Let A be a finitely generated abelian group. By the definition of a finitely generated abelian group there exists an epimorphism $\psi\colon \mathbb{Z}^m \to A$. Since $\mathbb{Z}$ is a Noetherian ring we know that $\ker(\psi)$ is again a finitely generated free abelian group of rank $n \leq m$. In particular there exists an isomorphism $v\colon \mathbb{Z}^n \to \ker(\psi)$. We denote by V the $m \times n$–matrix that represents the resulting map $\mathbb{Z}^n \to \ker(\psi) \subset \mathbb{Z}^m$ with respect to the standard bases. Then $A \cong \mathbb{Z}^m / V\mathbb{Z}^n$. We pick matrices A and B as in (2). From (1) it follows that $\mathbb{Z}^m / V\mathbb{Z}^n$ is isomorphic to $\mathbb{Z}^m / AVB\mathbb{Z}^n$. But the latter is isomorphic to $\mathbb{Z}_{p_1} \oplus \cdots \oplus \mathbb{Z}_{p_t} \oplus \mathbb{Z}^{m-n}$. ■

Definition. Let A be an abelian group.

(1) If A is finitely generated, then we refer to the r in the statement of the Finitely Generated Abelian Group Classification Theorem 51.4 as the rank of the finitely generated abelian group A. We denote it by $\mathrm{rank}(A)$.[536]

(2) We refer to

$$\mathrm{Tor}(A) \;:=\; \{a \in A \mid \text{ there exists an } n \in \mathbb{N} \text{ with } na = 0\}$$

as the torsion subgroup of A.[537] If $\mathrm{Tor}(A)$ is the trivial subgroup, then we say that A is torsion-free.

In the following three lemmas we collect several basic facts about finitely generated abelian groups. Most of the statements follow more or less directly from the Finitely Generated Abelian Group Classification Theorem 51.4. We will not prove the lemmas. We leave it to the reader to deduce the statements from the Finitely Generated Abelian Group Classification Theorem 51.4 and the algebra course the reader took.

Lemma 51.7. (Rank Additivity Lemma) Let

$$0 \;\to\; A \;\to\; B \;\to\; C \;\to\; 0$$

[536] If A is a finitely generated free abelian group, then this definition of rank agrees with the definition given for free abelian groups on page 1147.

[537] In Exercise 51.16 we will see that A is indeed a subgroup.

be a short exact sequence of abelian groups[538] such that at least two of these groups are finitely generated. Then the following holds:

(1) all three groups are finitely generated abelian groups,
(2) $\operatorname{rank}(B) = \operatorname{rank}(A) + \operatorname{rank}(C)$,
(3) if A and C are torsion-free, then B is also torsion-free.

Remark. Let B be a finitely generated group and let $\varphi\colon B \to C$ be an epimorphism. Note that C is evidently also finitely generated. If B is abelian it thus follows from the Rank Additivity Lemma 51.7 (1) that the kernel $\ker(\varphi)$ is also finitely generated. Note that if B is not abelian, then this conclusion does not necessarily hold. For example in Exercise 51.17 we will give an example of a group epimorphism $\varphi\colon B \to C$ from a non-commutative group B on two generators onto an abelian group C, such that the kernel is infinitely generated.

Lemma 51.8. Let $A \in \mathrm{M}(n \times n, \mathbb{Z})$ be a matrix. Then

$$\mathbb{Z}^n/A\mathbb{Z}^n \text{ is finite} \quad \Longleftrightarrow \quad \det(A) \neq 0.$$

Furthermore, if $\det(A) \neq 0$, then

$$0 \;\to\; \mathbb{Z}^n \;\xrightarrow{A\cdot}\; \mathbb{Z}^n \;\to\; \mathbb{Z}^n/A\mathbb{Z}^n \;\to\; 0$$

is a short exact sequence and $\mathbb{Z}^n/A\mathbb{Z}^n$ is a finite group with $|\det(A)|$ elements.

We also have the following lemma.

Lemma 51.9.

(1) If A, B and C are finitely generated abelian groups, then

$$A \oplus C \cong B \oplus C \quad \Longrightarrow \quad A \cong B.$$

(2) Let A be a subgroup of an abelian group B.
   (a) $\operatorname{Tor}(A)$ is a subgroup of $\operatorname{Tor}(B)$.
   (b) If B is finitely generated, then A is also finitely generated, and we have the inequality $\operatorname{rank}(A) \leq \operatorname{rank}(B)$.
(3) If A is a subgroup of a free abelian group of rank r, then A is a free abelian group with rank less or equal than r.[539]
(4) If A is a subgroup of a free abelian group B and if $\operatorname{rank}(A) < \operatorname{rank}(B)$, then A is a proper subgroup, i.e. $A \neq B$.
(5) Let $\varphi\colon A \to B$ be a homomorphism between two finitely generated abelian groups that are abstractly isomorphic.[540] If φ is an epimorphism, then φ is already an isomorphism.
(6) If A is a finitely generated abelian group and $\varphi\colon A \to B$ is an epimorphism, then B is also finitely generated and $\operatorname{rank}(A) \geq \operatorname{rank}(B)$.

Abelian groups that are not finitely generated are not classified and they tend to be significantly harder to deal with. For example the following lemma shows that not every torsion-free abelian group is a free abelian group.

---

[538] Recall that this means that the map $A \to B$ is injective, that $B \to C$ is surjective and that the image of $A \to B$ agrees with the kernel of $B \to C$.

[539] In fact this statement is already contained in the Subgroup-of-Free Abelian Group Lemma 51.2.

[540] For example A and B could be two free abelian groups of the same finite rank.

Lemma 51.10. The abelian group $(\mathbb{Q}, +)$ is torsion-free but not free abelian.

Proof. Clearly $(\mathbb{Q}, +)$ is torsion-free. If it was free abelian, then there would exist an epimorphism to $\mathbb{Z}$. In Exercise 51.1 we will show that such an epimorphism cannot exist. ■

In Exercise 51.3 (1) we will see that the conclusion of Lemma 51.9 (1) does not hold for general abelian groups. But the following statement actually does hold.

Proposition 51.11. Let A and B be any two abelian groups. If C is a finitely generated abelian group, then

$$A \oplus C \cong B \oplus C \quad \Longrightarrow \quad A \cong B.$$

Proof. We will consider a special case in Exercise 51.3 (b). The general case is proved in [**Cohn1956, WalkE1956**]. ■

51.2. **The free product of groups.** We first recall the definition of the direct product of two groups G and H that we already gave on page 1092.

Definition. The direct product of two groups G and H is defined as

$$G \times H \ := \ \{(g, h) \mid g \in G \text{ and } h \in H\}$$

together with the group structure that is given by

$$(g_1, h_1) \cdot (g_2, h_2) \ := \ (g_1 g_2, h_1 h_2)$$

for $g_1, g_2 \in G$ and $h_1, h_2 \in H$. We call the group $G \times H$ the direct product of the groups G and H. Via the monomorphisms

$$\begin{array}{ccc} G & \to & G \times H \\ g & \mapsto & (g, e) \end{array} \quad \text{and} \quad \begin{array}{ccc} H & \to & G \times H \\ h & \mapsto & (e, h) \end{array}$$

we can view G and H as subgroups of $G \times H$. Note that these subgroups commute, i.e. for every $g \in G$ and $h \in H$ we have the equality $(g, e) \cdot (e, h) = (g, h) = (e, h) \cdot (g, e)$.

Now we will introduce the "free product" $G * H$ of two groups G and H. The definition is perhaps initially harder than the definition of the "direct product" $G \times H$. But for many, perhaps even most applications, the free product is more useful.

Definition. Let G be and H be two groups. We consider the set $G * H$ of all finite sequences $(x_1, \ldots, x_m)$ such that the following conditions are satisfied:

(a) each x_i lies in one of the groups G or H,
(b) no x_j is the neutral element of G or of H,
(c) any two consecutive x_j's lie in two different groups.

Here we also allow the "empty sequence" (). Such sequences are sometimes called reduced words in G and H.

Let $(x_1, \ldots, x_m)$ and $(y_1, \ldots, y_n)$ be two elements in $G * H$. We define the product of these two elements as follows:

(1) First suppose that x_m and y_1 lie in different groups. Then we define

$$(x_1, \ldots, x_m) \cdot (y_1, \ldots, y_n) \ := \ (x_1, \ldots, x_m, y_1, \ldots, y_n).$$

(2) Now suppose that x_m and y_1 lie in the same group. Let $j \in \{1, \dots, \min\{m,n\}\}$ be the maximal element such that $x_{m+1-i} = y_i^{-1}$ for $i = 1, \dots, j$. If $j < \min\{m,n\}$, then we define[541]

$$(x_1, \dots, x_m) \cdot (y_1, \dots, y_n) \;:=\; (x_1, \dots, \underbrace{x_{m-j} \cdot y_{j+1}}_{\neq e}, \dots, y_n).$$

If $j = m$, then we define

$$(x_1, \dots, x_m) \cdot (y_1, \dots, y_n) \;:=\; (y_{m+1}, \dots, y_n).$$

We proceed similarly if $j = n$.

Another way of stating the product formula is as follows: given two sequences $(x_1, \dots, x_m)$ and $(y_1, \dots, y_n)$ we stack them together $(x_1, \dots, x_m, y_1, \dots, y_n)$ and then we delete any occurrence of a subsequence of the form a, a^{-1} for $a \in G$ or $a \in H$ and if a subsequence is of the form a, b with $a, b \in G$ or $a, b \in H$, then we replace it by ab.

We henceforth refer to $G * H$ together with this product structure as the free product of G and H.

We have the following important lemma.

Lemma 51.12. The free product of two groups G and H is again a group. The neutral element of $G * H$ is hereby given by the empty sequence $()$ and the inverse of an element $(x_1, \dots, x_m) \in G * H$ is given by

$$(x_1, \dots, x_m)^{-1} \;=\; (x_m^{-1}, \dots, x_1^{-1}) \;\in\; G * H.$$

Proof. It is clear that the empty sequence is a neutral element. It follows immediately from the definition of the product that the inverse of an element $(x_1, \dots, x_m) \in G * H$ is given by $(x_m^{-1}, \dots, x_1^{-1})$. It remains to show that the multiplication satisfies associativity.

In principle one can show associativity naively "by hand", but there are surprisingly many cases one needs to distinguish, so that the proof becomes rather painful.

We will therefore follow a different approach. We write $W = G * H$ and we denote by $(P(W), \circ)$ the group of all permutations of W, i.e. $P(W)$ is the set of all bijections from W to W and the group structure is given by composition of maps. For $g \in G$ we consider the map[542]

$$\begin{array}{rcl} \lambda_g \colon W & \to & W \\ (x_1, \dots, x_m) & \mapsto & \begin{cases} (g, x_1, x_2, \dots, x_m), & \text{if } x_1 \in H, \\ (gx_1, x_2, \dots, x_m), & \text{if } x_1 \in G \text{ and } g \neq x_1^{-1}, \\ (x_2, \dots, x_m), & \text{if } g = x_1^{-1}. \end{cases} \end{array}$$

It is now straightforward to see that for any $g, g' \in G$ and any $(x_1, \dots, x_m) \in W$ we have $g(g' \cdot (x_1, \dots, x_m)) = (gg') \cdot (x_1, \dots, x_m)$. This means that $\lambda_g \circ \lambda_{g'} = \lambda_{gg'}$. It is now straightforward to see that the map

$$\begin{array}{rcl} \lambda \colon G & \to & P(W) \\ g & \mapsto & \lambda_g \end{array}$$

[541] Since x_m and y_1 lie in the same group, the elements x_{m-j} and y_{j+1} also lie in the same group, so it makes sense to consider $x_{m-j} \cdot y_{j+1}$.

[542] It is straightforward to see that the sequences on the right do indeed lie in $G * H$.

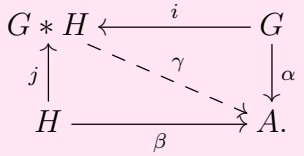
is a group homomorphism. Similarly we define $\lambda\colon H \to P(W)$. Now we consider the map

$$\begin{array}{rcl} \lambda\colon W & \to & P(W) \\ (x_1, \ldots, x_n) & \mapsto & \lambda_{x_1} \circ \cdots \circ \lambda_{x_n}. \end{array}$$

This map is injective since $\lambda(x_1, \ldots, x_n)$ applied to the empty word $()$ gives the word $(x_1, \ldots, x_n)$. Hence $\lambda(x_1, \ldots, x_n)$ is not the identity map from $W \to W$, i.e. $\lambda(x_1, \ldots, x_n)$ is non-trivial in $P(W)$.

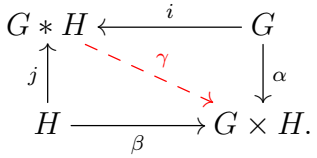
Furthermore the map $\lambda\colon W \to P(W)$ satisfies $\lambda(x \cdot y) = \lambda_x \circ \lambda_y$. Put differently, λ defines an injective map $\lambda\colon (W, \cdot\,) \to (P(W), \circ)$ that preserves the product structure. But since $(P(W), \circ)$ satisfies the associativity law we now see that $(W, \cdot\,)$ also satisfies the associativity law. ∎

The following lemma summarizes two main properties of the free product of two groups.



Lemma 51.13. Let G and H be two groups. The following two statements hold:

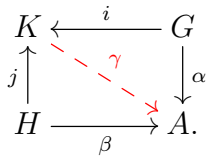
(1) The maps



$$\begin{array}{rcl} i\colon G & \to & G * H \\ g & \mapsto & \begin{cases} (g), & \text{if } g \neq e, \\ (), & \text{if } g = e \end{cases} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} j\colon H & \to & G * H \\ h & \mapsto & \begin{cases} (h), & \text{if } h \neq e, \\ (), & \text{if } h = e \end{cases} \end{array}$$

are monomorphisms.

(2) For any two group homomorphisms $\alpha\colon G \to A$ and $\beta\colon H \to A$ there exists a unique group homomorphism $\gamma\colon G * H \to A$ such that the following diagram commutes



Example. Let G and H be groups. We denote by $\alpha\colon G \to G \times H$ and $\beta\colon H \to G \times H$ the obvious inclusion maps. It follows from Lemma 51.13 there exists a unique homomorphism $\gamma\colon G * H \to G \times H$ which makes the following diagram commute:

Remark. In the literature the direct product of two groups often gets introduced in a slightly different way, namely by a "universal property". More precisely, let G be and H be two groups. The *direct product of G and H* is then defined as a group K together with two homomorphisms $i\colon G \to K$ and $j\colon G \to K$ which satisfy the following universal property: for every two group homomorphisms $\alpha\colon G \to A$ and $\beta\colon H \to A$ there exists a *unique* group

homomorphism $\gamma\colon K \to A$ such that the following diagram commutes

Lemma 51.13 can now be reinterpreted as saying that the direct product of two groups always exists. An argument that is very similar to the one we gave on page 1149 shows that the direct product is unique in the following sense: If $(K, i\colon G \to K, j\colon H \to K)$ and $(K', i'\colon G \to K', j'\colon H \to K')$ both satisfy the above universal property, then there exists a unique isomorphism $\Phi\colon K \to K'$ such that $i' = \Phi \circ i$ and $j' = \Phi \circ j$. [543]

Proof. It is clear that the maps i and j are injective, furthermore it follows immediately from the definition of the group structure on $G*H$ that the maps are group homomorphisms.

Now let $\alpha\colon G \to A$ and $\beta\colon H \to A$ be two group homomorphisms. For an element $(g_1, h_1, \dots, g_k, h_k) \in G * H$ with $g_i \in G, h_i \in H$, $i = 1, \dots, n$ we define

$$\gamma(g_1, h_1, \dots, g_k, h_k) \;:=\; \alpha(g_1) \cdot \beta(h_1) \cdot \dots \cdot \alpha(g_k) \cdot \beta(h_k).$$

The same way we define γ for all other elements in $G * H$. Now one can show easily that γ is a group homomorphism.

It remains to show the uniqueness of γ. Any element in $G * H$ is a product of elements of the form $i(g)$, $g \in G$ and $j(h)$, $h \in H$. It follows that any homomorphism $\delta\colon G * H \to A$ is already uniquely determined by the values of δ on all elements of the form $i(g)$, $g \in G$ and $j(h)$, $h \in H$. Put differently, there is at most one homomorphism $\delta\colon G * H \to A$ with $\delta(i(g)) = \alpha(g)$ for all $g \in G$ and $\delta(i(h)) = \beta(h)$ for all $h \in H$. ■

Remark.

(1) We will use the monomorphisms from Lemma 51.13 to view G and H as subgroups of $G * H$.

(2) If there is no danger of confusion, then we often shorten $(x_1, \dots, x_m) \in G * H$ to the notation $x_1 \dots x_m$. This notation is coherent with the convention (1). Note that if $g \in G$ and $h \in H$ are non-trivial elements, then the sequences (g, h) and (h, g) both lie in $G * H$ and they are different. With the convention that we just introduced that means that $g \cdot h \neq h \cdot g$. Put differently, a non-trivial element of G never commutes with a non-trivial element of H.

(3) The construction of the free product of two groups generalizes in an obvious way to the free product of finitely many, in fact even to infinitely many groups.

Let t be a symbol. We define

$$\langle t \rangle \;:=\; \{\dots, t^{-2}, t^{-1}, e, t, t^2, \dots\}.$$

The set $\langle t \rangle$ admits an obvious group structure that is given by $t^i \cdot t^j := t^{i+j}$. This group is called *the infinite cyclic group generated by* t. The map $\mathbb{Z} \to \langle t \rangle$, $n \mapsto t^n$ is evidently an isomorphism. Now we come to one of the main definitions in group theory.

[543] Why does $K = G \times H$ with the obvious maps $i\colon G \to K$ and $j\colon H \to K$ not satisfy this universal property? Or does it?

Definition. For a set S we refer to

$$\langle S \rangle \ := \ \text{free product of the groups } \langle s \rangle,\ s \in S$$

as the free group on the (generating) set S. Via the map $s \mapsto (s)$ we can and will view S as a subset of $\langle S \rangle$.

Example. If $S = \{t_1, \ldots, t_k\}$, then we obtain the group

$$\langle t_1, \ldots, t_k \rangle \ := \ \langle t_1 \rangle * \cdots * \langle t_k \rangle$$

which we also refer to as the *free group on the generators* $t_1, \ldots, t_k$. Each element of the free group $\langle t_1, \ldots, t_k \rangle$ is thus of the form

$$t_{r_1}^{s_1} t_{r_2}^{s_2} \ldots t_{r_l}^{s_l}$$

with $r_i \neq r_{i+1}$ for $i = 1, \ldots, l-1$ and $s_i \neq 0$ for $i = 1, \ldots, l$.

Convention. Sometimes we denote the free group on k generators just by F_k.

Example. We consider the free group $\langle x, y \rangle$ on the two generators x and y. Elements in this group are of the form $xy^3x^{-2}y$ or $y^{-2}xy$. The multiplication is the "obvious one", for example

$$(xy^3x^{-1}y^2) \cdot (y^{-2}x^3yxy^{-1}) \ = \ xy^3x^2yxy^{-1}.$$

The group is not abelian since $xy \neq yx$.[544]

Lemma 51.14. Let S be a set. The free group $\langle S \rangle$ is torsion-free. In other words, every non-trivial element in the free group $\langle S \rangle$ has infinite order.

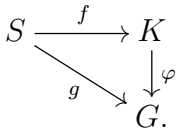
Proof. We will prove the lemma in Exercise 51.4. ■

The following innocent looking lemma summarizes the key property of free groups.

Lemma 51.15. Let S be a set, let G be an arbitrary group and let $g\colon S \to G$ be a map. Then there exists a unique homomorphism $\varphi\colon \langle S \rangle \to G$ with $\varphi(s) = g(s)$ for every $s \in S$.

Proof. For $s \in S$ the map

$$\begin{array}{ccc} \langle s \rangle & \to & G \\ s^n & \mapsto & g(s)^n \end{array}$$



is evidently the unique homomorphism $\varphi_s\colon \langle s \rangle \to G$ with $\varphi_s(s) = g(s)$. It now follows from the obvious generalization of Lemma 51.13 to the case of the free product of arbitrarily many groups that there exists a unique homomorphism $\varphi\colon \langle S \rangle \to G$ with $\varphi(s) = \varphi_s(s) = g(s)$ for $s \in S$. ■

Remark. Sometimes in the literature free groups are defined via a universal property. More precisely, let S be a set. A *free group on* S is sometimes defined as a group K together with a map $f\colon S \to K$ which satisfies the following universal property: for any map $g\colon S \to G$ from the set S to a group G[545] there exists a unique group homomorphism

[544] Why is $xy \neq yx$?

[545] Note that in contrast to Lemma 51.1, the group G is now not necessarily abelian.

$\varphi\colon K \to G$ such that the following diagram commutes

In this language our above Lemma 51.15 says that the obvious map $S \to \langle S\rangle$ is a free group on S in the above sense. As before, a slight variation on the argument on page 1149 shows that the free group on S is unique in an appropriate sense.

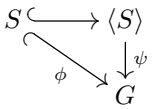
Definition.

(1) A group G is called free, if it is isomorphic to the free group $\langle S\rangle$ on some set S. We say a subset $S \subset G$ is a basis, if the natural map[546] $\langle S\rangle \to G$ is an isomorphism.
(2) Given group G we say that $S \subset G$ is a generating setif the natural homomorphism $\langle S\rangle \to G$ is an epimorphism.Sometimes we also say that the elements in S are generators of G.
(3) We say that a group G is finitely generated if it admits a finite generating set.

Examples.

(1) As on page 1074 we consider the following two self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1) \end{array}$$



and we denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means that

$$G = \begin{array}{c} \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}. \end{array}$$

We saw in Exercise 25.11 that $\mathbb{R}^2/G$ equals the Klein bottle K and using the Fundamental Group-via-Actions Theorem 48.16 we saw on page 1091 that $\pi_1(\text{Klein bottle}) \cong G$. The group G is finitely generated in the above sense. More precisely, it follows immediately from the definition of G that $S = \{A, B\} \subset G$ is a generating set for G.
(2) For any set S there exists by Lemma 51.15 a unique homomorphism $\langle S\rangle \to \mathbb{Z}^{(S)}$ that sends $s \in S$ to s viewed as an element in $\mathbb{Z}^{(S)}$. Since the set $S \subset \mathbb{Z}^{(S)}$ generates $\mathbb{Z}^{(S)}$ we see that this homomorphism is an epimorphism. It follows that any finitely generated abelian group in the sense of page 1149 is also a finitely generated group in the above sense.

The subgroup of a free abelian group is again a free abelian group. Does the same hold for free groups? We record this as a question for future reference.

[546]Here we mean by "canonical map $\langle S\rangle \to G$" the unique homomorphism $\psi\colon \langle S\rangle \to G$ from Lemma 51.15 that makes the following diagram commute

where $S \to G$ is the inclusion map.

Question 51.16. Is every subgroup of a free group again a free group?

The next lemma says in particular that free groups on two sets are isomorphic if and only if the cardinalities of the sets are the same.

Lemma 51.17. Let S and T be two sets.

(1) If there exists an epimorphism $\langle S\rangle \to \langle T\rangle$, then $\#S \geq \#T$.
(2) If $\langle S\rangle$ is isomorphic to $\langle T\rangle$, then $\#S = \#T$.
(3) If given $n \in \mathbb{N}$ we denote by F_n the free group on n generators, then for $k \neq l$ the groups F_k and F_l are not isomorphic.

Proof.

(1) We first recall that we had just seen in the previous example that for any set U there exists a unique epimorphism $\psi_U\colon \langle U\rangle \to \mathbb{Z}^{(U)}$ that sends $u \in U$ to u viewed as an element in $\mathbb{Z}^{(U)}$.

Now let S and T be two sets and let $\varphi\colon \langle S\rangle \to \langle T\rangle$ be an epimorphism. By Lemma 51.1 there exists a unique homomorphism $\widetilde{\varphi}\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ that sends $s \in S$ to $\psi_T(\varphi(s)) \in \mathbb{Z}^{(T)}$. We obtain the following diagram of homomorphisms

$$\begin{array}{ccc} \langle S\rangle & \xrightarrow{\ \varphi\ } & \langle T\rangle \\ {\scriptstyle\psi_S}\downarrow & & \downarrow{\scriptstyle\psi_T} \\ \mathbb{Z}^{(S)} & \xrightarrow{\ \widetilde{\varphi}\ } & \mathbb{Z}^{(T)}. \end{array}$$

It follows immediately from the definition of $\widetilde{\varphi}$ that this diagram commutes.[547] Since the top horizontal is an epimorphism and since the vertical maps are epimorphisms we see that the bottom horizontal map is also an epimorphism. It follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that $\#S \geq \#T$.

(2) Let $f\colon \langle S\rangle \to \langle T\rangle$ be an isomorphism. We apply (1) to f and to f^{-1} and we obtain that $\#S \geq \#T$ and $\#T \geq \#S$. It follows from the Bernstein-Schröder Theorem 0.11 that $\#S = \#T$.

(3) This statement is an immediate consequence of (2).[548] ∎

51.3. **An alternative definition of the free product of groups.** For some purposes it is sometimes useful to work with a different model for the free product of two groups.

Definition. Let A and B be two groups. We set[549]

$$S(A,B) \ := \ \{\text{all finite sequences } (g_1,\ldots,g_k) \text{ with each } g_i \text{ in } A \text{ or } B\}$$

[547] Here we use that a homomorphism $\gamma\colon \langle S\rangle \to G$ is uniquely determined by the values of γ on S. Put differently, if $\alpha\colon \langle S\rangle \to G$ and $\beta\colon \langle S\rangle \to G$ are two homomorphisms with $\alpha(s) = \beta(s)$ for all $s \in S$, then it follows immediately from the uniqueness statement of Lemma 51.15 that $\alpha = \beta$.

[548] Note that if we just want to prove Statement (3), then in the proof of (2) we could replace the slightly esoteric the Subgroup-of-Free Abelian Group Lemma 51.2 by the more conventional the Rank Additivity Lemma 51.7 that was proved in the Algebra course.

and we denote by $\sim$ the equivalence relation on $S(A,B)$ that is generated by the relations

$$(g_1,\dots,g_l,e,g_{l+2},\dots,g_k) \sim (g_1,\dots,g_l,g_{l+2},\dots,g_k)$$

and by the relations

$$(g_1,\dots,g_l,g_{l+1},\dots,g_k) \sim (g_1,\dots,g_lg_{l+1},\dots,g_k)$$

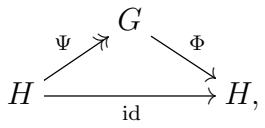
if both g_l and g_{l+1} lie in A or both lie in B. It is now straightforward to verify that the map

$$\begin{array}{rcl} S(A,B)/\sim \times S(A,B)/\sim & \to & S(A,B)/\sim \\ ([(g_1,\dots,g_k)],[h_1,\dots,h_l]) & \mapsto & [(g_1,\dots,g_k,h_1,\dots,h_l)] \end{array}$$

is well-defined and that it defines a group structure on $S(A,B)/\sim$.[550]

Proposition 51.18. Let A and B be two groups. Then the map[551]

$$\begin{array}{rcl} \Phi\colon S(A,B)/\sim & \to & A*B \\ [(g_1,\dots,g_k)] & \mapsto & g_1\cdot\dots\cdot g_k \end{array}$$



is well-defined and it is an isomorphism. The inverse map is given by

$$\begin{array}{rcl} \Psi\colon A*B & \to & S(A,B)/\sim \\ (g_1,\dots,g_k) & \mapsto & [(g_1,\dots,g_k)]. \end{array}$$

In the proof of Proposition 51.18 we will need the following little lemma.

Lemma 51.19. Let $\Phi\colon G\to H$ and $\Psi\colon H\to G$ be two group homomorphisms such that $\Phi\circ\Psi=\mathrm{id}_H$ and such that Ψ is an epimorphism. Then Φ is an isomorphism.

The lemma can be summarized as follows, if we are given a commutative diagram of the form

then Φ is an isomorphism.[552]

Proof. It follows from $\Phi\circ\Psi=\mathrm{id}_H$ that Φ is an epimorphism. It remains to show that Φ is a monomorphism. So let $g\in\ker(\Phi)$. Since Ψ is an epimorphism there exists an $h\in H$ with $\Psi(h)=g$. Since $\Phi\circ\Psi=\mathrm{id}_H$ we see that $h=\Phi(\Psi(h))=\Phi(g)=e$. Thus $h=e$ and thus $g=\Psi(h)=\Psi(e)=e$. ∎

Proof. It is straightforward to verify that the map

$$\begin{array}{rcl} \Phi\colon S(A,B)/\sim & \to & A*B \\ [(g_1,\dots,g_k)] & \mapsto & g_1\cdot\dots\cdot g_k \end{array}$$

[549]This definition is similar to the definition of $A*B$, but now we allow that elements of the sequence are trivial and we allow that consecutive elements lie in the same group.
[550]The neutral element is again represented by the empty sequence ( ) and the inverse of $[(g_1,\dots,g_k)]$ is given by $[(g_k^{-1},\dots,g_1^{-1})]$. This time associativity is not a problem. Why not?
[551]Recall that we use the canonical monomorphisms from Lemma 51.13 to view A and B as subgroups of $A*B$. If we want to be more precise, then we could say that Φ is given by $[(g_1,\dots,g_k)]\mapsto(g_1)\cdot\dots\cdot(g_k)$.
[552]Is Ψ also necessarily an isomorphism?

is well-defined and that it is a homomorphism. This homomorphism is surjective since $A * B$ is a subset of $S(A, B)$. Next we consider the map[553]

$$\begin{array}{rcl} \Psi\colon A * B & \to & S(A,B)/\sim \\ (g_1, \ldots, g_k) & \mapsto & [(g_1, \ldots, g_k)]. \end{array}$$

It is straightforward to see that Ψ is a homomorphism. It is clear that $\Phi \circ \Psi = \mathrm{id}_{A*B}$. It is not so obvious that $\Psi \circ \Phi = \mathrm{id}_{S(A,B)/\sim}$. In fact we will proceed in a slightly different fashion: to show that Φ is an isomorphism it suffices, according to Lemma 51.19, to show that Ψ is surjective. This in turn follows from the following claim.

Claim. Any element in $S(A, B)$ is equivalent to an element in $A * B$.

Proof. We prove the claim by induction on the length of a sequence in $S(A, B)$. Clearly the claim holds for all sequences of length 0. Suppose we already know the claim for all sequences of length $\leq k-1$. Let $(g_1, \ldots, g_k)$ be a sequence of length k. If $(g_1, \ldots, g_k) \in A*B$, then we are done. Now suppose that this is not the case. Then one of the following occurs:

(1) either there exists an $i \in \{1, \ldots, k\}$ with $g_i = e$, or
(2) there exists an $i \in \{1, \ldots, k-1\}$ with $g_i, g_{i+1} \in A$, or
(3) there exists an $i \in \{1, \ldots, k-1\}$ with $g_i, g_{i+1} \in B$.

In the first case the sequence is equivalent to $(g_1, \ldots, g_{i-1}, g_{i+1}, \ldots, g_k)$. In the second and third case the sequence is equivalent to $(g_1, \ldots, g_{i-1} \cdot g_{i+1}, \ldots, g_k)$. In all three cases we have thus shown that our original sequence is equivalent to a sequence of length $k-1$. So we are done by our induction hypothesis. ∎

Let A and B be two groups. In the following we will use the isomorphism of Proposition 51.18 to identify the group $S(A, B)/\sim$ with the free product $A * B$. Both groups have their advantages:

(1) In the group $S(A, B)/\sim$ it is easier to write down the product of two elements, we just need to juxtapose sequences of elements in A and B.
(2) On the other hand in the group $A*B$ it is trivial to check whether two elements are the same. For example for two non-trivial elements $a \in A$ and $b \in B$ the elements (a, b) and (b, a) of $A * B$ are by definition different. But from the definition of $S(A, B)/\sim$ it is not immediately clear that $[(a, b)]$ and $[(b, a)]$ are indeed different.

51.4. The Grushko-Neumann Theorem.

We start out with the following natural definition.

Definition. Let G be a finitely generated group. We denote by $d(G) \in \mathbb{N}_0$ the minimal number of elements in a generating set for G.

Remark. It is an unfortunate fact of life that in the literature the number $d(G)$ is usually referred to as the rank of the group G. But for abelian groups the invariants $\mathrm{rank}(G)$ and $d(G)$ can differ quite dramatically. For example for $G = (\mathbb{Z}_2)^n$ we have $\mathrm{rank}(G) = 0$ but $d(G) = n$.

The following theorem was proved by Igor Grushko [**Gru1940**] in 1940 and independently by Bernhard Neumann [**Neum1943**] in 1940.

[553]Put differently, $A * B \to S(A, B)/\sim$ is the homomorphism that is given by the universal property of $A * B$.

Theorem 51.20. (Grushko-Neumann Theorem) Given any two finitely generated groups A and B we have $$d(A * B) \;=\; d(A) + d(B).$$

Proof. The proof is evidently given in the above two references, but it can also be found in any self-respecting book on combinatorial group theory, see e.g. [**LyS1977**, Corollay IV.1.9] and [**MKS1976**, p. 192]. ■

We already saw that some groups can be written as a direct product of two groups in different ways. For example it follows from the Chinese Remainder Theorem that the groups $\mathbb{Z}_3 \times \mathbb{Z}_{35}$ and $\mathbb{Z}_5 \times \mathbb{Z}_{21}$ are isomorphic. The following theorem says that the situation is much more rigid for free products. Before we can state the theorem we have to introduce the following definition.

Definition. A group G is indecomposable if it is not isomorphic to the free product of two non-trivial groups.

Lemma 51.21. Abelian groups and finite groups are indecomposable.

Proof. The lemma will be proved in Exercise 51.6. ■

Now we can state the Grushko[554] Decomposition Theorem.

Theorem 51.22. (Grushko Decomposition Theorem) Let G be a finitely generated group.

(1) The group G is isomorphic to the free product $G = A_1 * \cdots * A_k$ of non-trivial indecomposable groups.[555]
(2) The isomorphism types of $A_1, \ldots, A_k$ are unique up to permutation. More precisely, if $A_1, \ldots, A_k$ and $B_1, \ldots, B_l$ are indecomposable finitely generated groups such that
$$A_1 * \cdots * A_k \;\cong\; B_1 * \cdots * B_l,$$
then $k = l$ and furthermore there exists a permutation $\sigma \in S_k$ such that $A_i \cong B_{\sigma(i)}$ for $i = 1, \ldots, k$.

Proof.

(1) This statement follows easily from induction on $d(G)$ and the Grushko-Neumann Theorem 51.20. Indeed, if $d(G) = 0$ then there is nothing to prove. Next suppose that the statement is known for all groups G with $d(G) < k$. Let G be a group with $d(G) = k$. If G is indecomposable, we are done. If G is not indecomposable, then we can write G as the free product of two non-trivial groups A and B. By the Grushko-Neumann Theorem 51.20 we have $d(G) = d(A) + d(B)$. Since A and B are non-trivial we have $d(A) \geq 1$ and $d(B) \geq 1$. Thus we have $d(A) < k$ and $d(B) < k$ and by induction we can find decompositions for A and B. These two decompositions put together give the desired decomposition for $G = A * B$.
(2) The uniqueness statement was proved by Aleksandr Kurosh in 1934, see [**Kuro1934**, Isomorphismsatz] and [**Kuro1960**, p. 27]. Alternative proofs are given in [**Stal1975**, p. 168f] and [**Nel**, Theorem 4.5]. Also see [**CM1982**, Chapter II.4] for more context. ■

[554] Igor Grushko was a Russian mathematician. The theorem was proved in 1940.
[555] If G is trivial then $k = 0$ and the free product of zero groups is by convention the trivial group.

Example. It follows from Lemma 51.21 and from the Grushko Decomposition Theorem 51.22 that the free product $\mathbb{Z}_3 * \mathbb{Z}_{35}$ is not isomorphic to the free product $\mathbb{Z}_5 * \mathbb{Z}_{21}$.

Exercises for Chapter 51.

Exercise 51.1. Show that $\mathbb{Q}$ does not admit an epimorphism onto $\mathbb{Z}$.

Exercise 51.2. Given $n \in \mathbb{Z}$ we consider the matrix $B(n) = \begin{pmatrix} 0 & 3 \\ 3 & n \end{pmatrix}$ and we consider the abelian group $A_n := \mathbb{Z}^2/B(n)\mathbb{Z}^2$. Complete the following sentence: given $m, n \in \mathbb{Z}$ the abelian groups A_m and A_n are isomorphic if and only if ....

Exercise 51.3.

(a) Show that there exists an abelian group G with $G \oplus G \cong G$.

(b) Let A be a finitely generated abelian group. Show that if B is an abelian group with $B \oplus A \cong A$, then $B \cong 0$.
Hint. Arguably it is easiest to start out with the special case that $A = \mathbb{Z}$.

Exercise 51.4. . Let S be a set. Show that every non-trivial element in the free group $\langle S \rangle$ has infinite order.

Exercise 51.5. Let M be a connected smooth manifold, let $P_1, \ldots, P_n$ and $Q_1, \ldots, Q_n$ be points on M. Does there exist an action by a free group F on M such that for any $i \in \{1, \ldots, n\}$ there exists a $g \in F$ with $g \cdot P_i = Q_i$?

Exercise 51.6. Show that abelian groups and finite groups are indecomposable.

Exercise 51.7. Let G be an additive abelian group. We say that an element $g \in G$ is *primitive* if there does not exist an $h \in G$ and an $n \geq 2$ with $n \cdot h = g$.

(1) Suppose G is finitely generated. Let $g \in G$. Show that the following statements are equivalent:
   (a) g is a primitive element.
   (b) We can write $G = \mathbb{Z} \cdot g \oplus H$ for some abelian group G.
   (c) There exists a homomorphism $\varphi\colon G \to \mathbb{Z}$ with $\varphi(g) = 1$.

(2) Which of the implications in (1) also hold for infinitely generated abelian groups?

Exercise 51.8. Let $p, q, r \in \mathbb{N}_{\geq 2}$ be coprime. By the Chinese Remainder Theorem we know that $\mathbb{Z}_{pq} \times \mathbb{Z}_r \cong \mathbb{Z}_p \times \mathbb{Z}_{qr}$. Show, without making use of the Grushko Decomposition Theorem, that $\mathbb{Z}_{pq} * \mathbb{Z}_r$ is not isomorphic to $\mathbb{Z}_p * \mathbb{Z}_{qr}$.
Perhaps it is notationally easier to write $A = \{e, a, \ldots, a^{pq-1}\}$, $B = \{e, b, \ldots, b^{r-1}\}$, $C = \{e, c, \ldots, c^{p-1}\}$ and $D = \{e, d, \ldots, d^{qr-1}\}$, where A, B, C and D have the obvious multiplicative group structure. Then the problem is to show that $A * B$ is not isomorphic to $C * D$.

Exercise 51.9. Let S and T be sets. If there exists a monomorphism $\varphi\colon \langle S \rangle \to \langle T \rangle$, does it follow that $\#S \leq \#T$?

Exercise 51.10. Let P be a property of groups. A group G is called *locally* P if every finitely generated subgroup has property P.

(1) Is every locally abelian group in fact an abelian group?

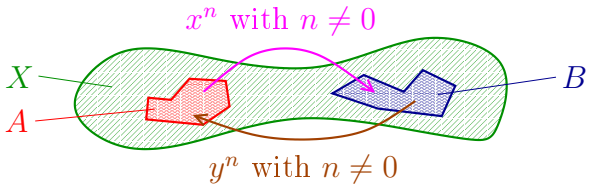
(2) Is every locally free group in fact a free group?
(3) Is every locally finite group in fact a finite group?

Exercise 51.11. Let A and B be two non-trivial groups. Show that the free product $A * B$ is infinite.

Exercise 51.12. Let G be a group and let $g \in G$. The *centralizer* of $g \in G$ is defined as

$$C_G(g) \;:=\; \{h \in G \,|\, gh = hg\}.$$

(a) Let A and B be groups and let $g \in A * B$. We view A and B as subgroups of $A * B$ in the obvious way. Let $g \in A * B$. Show that



$$C_G(g) \;=\; \begin{cases} C_A(g), & \text{if } g \in A, \\ C_B(g), & \text{if } g \in B, \\ \langle h \rangle, \quad h \in A * B \text{ of infinite order} & \text{otherwise.} \end{cases}$$

(b) Let S be a set. Show that every abelian subgroup of the free group $\langle S \rangle$ is isomorphic to $\mathbb{Z}$.
Remark. Note that S is not necessarily finite.

Exercise 51.13. Let G be a group and let $x, y \in G$. Suppose there exists an action of G on some set X and two disjoint subsets A and B of X such that the following two conditions are satisfied:

(1) for every $n \in \mathbb{Z} \setminus \{0\}$ we have $x^n \cdot A \subset B$, and
(2) for every $n \in \mathbb{Z} \setminus \{0\}$ we have $y^n \cdot B \subset A$.

Show that x and y generate a free subgroup of G, i.e. show that the map $\langle x \rangle * \langle y \rangle \to G$ is a monomorphism.
Hint. Show that any non-trivial element $(g_1, \ldots, g_k) \in \langle x \rangle * \langle y \rangle$ acts non-trivially on X.
Remark. This statement is known as the *Ping-Pong Lemma*.

Exercise 51.14. We consider the group $G = \mathrm{SL}(2, \mathbb{Z})$ and we consider the two matrices $x = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$, $y = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}$. Use the Ping-Pong Lemma from Exercise 51.13 to show that x and y generate a free subgroup of G.
Hint. Consider $X = \mathbb{R}^2$ together with the subsets $A = \{(x, y) \in \mathbb{R}^2 \,|\, |y| > |x|\}$ and $B = \{(x, y) \in \mathbb{R}^2 \,|\, |x| > |y|\}$.

Exercise 51.15. A group π is called *residually finite* if given any non-trivial element $g \in \pi$ there exists a homomorphism $\alpha \colon \pi \to G$ to a finite group G such that $\alpha(g)$ is non-trivial.

(a) Show that for any $n \in \mathbb{N}$ the group $\mathrm{GL}(n, \mathbb{Z})$ is residually finite.
(b) Show that the free group on two generators is residually finite.
Remark. Use Exercise 51.14.

Exercise 51.16. Let G be a group. We consider the subset

$$\mathrm{Tor}(G) \;:=\; \{g \in G \,|\, \text{ there exists an } n \in \mathbb{N} \text{ with } g^n = e\}.$$

(a) Suppose that G is abelian. Show that $\mathrm{Tor}(G)$ is a subgroup of G. We refer to it as the *torsion subgroup of* G.
(b) Give an example of a group G such that $\mathrm{Tor}(G)$ is not a subgroup of G.

Exercise 51.17.

(a) Let $\phi\colon \langle x, y\rangle \to \mathbb{Z}$ be the homomorphism given by $\phi(x) = 1$ and $\phi(y) = 0$. Show that $\ker(\phi)$ is infinitely generated.
Remark. In Proposition 53.14 we will see that any non-trivial *normal* subgroup of infinite index of a free group is infinitely generated.
(b) Let $\psi\colon \langle s, t\rangle \times \langle x, y\rangle \to \mathbb{Z}$ be the homomorphism given by $\psi(s) = 1$, $\psi(t) = 0$, $\psi(x) = 1$ and $\psi(y) = 0$. Show that $\ker(\psi)$ is finitely generated.

Exercise 51.18. We consider the free group $F = \langle x, y\rangle$. Let $a = (a_1, a_2, \ldots, a_m)$ be a reduced word in $\langle x\rangle$ and $\langle y\rangle$. We denote by $\overline{a} = (a_m, \ldots, a_1)$ the reverse word. Given any reduced word $z = (z_1, \ldots, z_n)$ we write

$$|z|_a \;=\; \text{number of non-overlapping subsequences of } z_1, \ldots, z_n \text{ that agree with } a_1, \ldots, a_m.$$

Now we consider the following map

$$\begin{array}{rcl} \varphi_a\colon \langle x, y\rangle & \to & \mathbb{Z}_{\geq 0} \\ z & \mapsto & |z|_a - |z|_{\overline{a}}. \end{array}$$

(a) Show that in general φ_a is not a homomorphism.
(b) Show that there exists a $D > 0$ such that for every $g, h \in \langle x, y\rangle$ we have

$$|\varphi_a(g \cdot h) - \varphi_a(g) - \varphi_a(h)| \;\leq\; D.$$

Remark. Any map $\varphi\colon G \to \mathbb{R}$ from a group G to $\mathbb{R}$ that admits a D as above is called a *quasi-morphism*. The above quasi-morphism is called the *Brooks quasi-morphism* [**Brooks1981**].

Exercise 51.19.

(a) Let $p, q \in \mathbb{N}$. Show that if p and q are coprime, then there exist $X, Y \in \mathrm{GL}(2, \mathbb{Z})$ with

$$X \cdot \begin{pmatrix} p & 0 \\ 0 & q \end{pmatrix} \cdot Y \;=\; \begin{pmatrix} x \cdot y & 0 \\ 0 & 1 \end{pmatrix}.$$

(b) Let $A \in \mathrm{M}(m \times n; \mathbb{Z})$. By the Smith Normal Form Theorem 51.5 we know that there exist matrices $P \in \mathrm{GL}(m, \mathbb{Z})$ and $Q \in \mathrm{GL}(n, \mathbb{Z})$ such that $P \cdot A \cdot Q$ is of the form

$$P \cdot A \cdot Q \;=\; \begin{pmatrix} D_{k\times k} & 0_{k\times(n-k)} \\ 0_{k\times(m-k)} & 0_{(n-k)\times(m-k)} \end{pmatrix}$$

where $D = \mathrm{diag}(d_1, \ldots, d_k)$ is a diagonal $(k \times k)$-matrix such that the diagonal entries $d_1, \ldots, d_k$ lie in $\mathbb{N}$. Show that we can find P and Q such that for each $i \in \{1, \ldots, k-1\}$ we have $d_i | d_{i+1}$.
(c) Show that $d_1, \ldots, d_k$ with $d_i | d_{i+1}$ as in (b) are unique.

Exercise 51.20. Show that every matrix in $\mathrm{GL}(n,\mathbb{Z})$ can be written as a product of elementary matrices, i.e. of matrices of the following form:

$$\underbrace{\begin{pmatrix} \mathrm{id} & 0 & 0 \\ 0 & r & 0 \\ 0 & 0 & \mathrm{id} \end{pmatrix}}_{\text{(I)}}, \quad \underbrace{\begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}}_{\text{(II)}} \quad \text{and} \quad \underbrace{\begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & r & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}}_{\text{(III)}}, \quad \text{with } r \in \{-1, 1\}.$$

Exercise 51.21. Let G and H be two groups.

(a) Suppose there exist monomorphisms $\varphi\colon G \to H$ and $\psi\colon H \to G$. Does it follow that G and H are isomorphic?

(b) Suppose there exist epimorphisms $\varphi\colon G \to H$ and $\psi\colon H \to G$. Does it follow that G and H are isomorphic?

52. The basic Seifert–van Kampen Theorem

We are still lacking the computation of fundamental groups of even fairly simple topological spaces. Now we will take a new approach to calculating fundamental groups. Namely in the following two chapters we will formulate and prove results which allow us to calculate the fundamental group of a given topological space from the fundamental groups of suitable subspaces.

52.1. **The formulation of the basic Seifert–van Kampen Theorem.** The idea of the Seifert–van Kampen theorem is to reduce the calculation of the fundamental group of a topological space X to the determination of fundamental groups of "simpler subsets" of X. Let X be a topological space and let $U, V \subset X$ be two subsets with $X = U \cup V$ and with $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$ and we consider the following inclusion maps and the corresponding induced homomorphisms of the fundamental groups:

$$\begin{array}{ccc} U \cap V & \longrightarrow & U \\ \downarrow & & \downarrow{\scriptstyle i} \\ V & \xrightarrow[j]{} & X = U \cup V \end{array} \qquad \text{and} \qquad \begin{array}{ccc} \pi_1(U \cap V, x_0) & \longrightarrow & \pi_1(U, x_0) \\ \downarrow & & \downarrow{\scriptstyle i_*} \\ \pi_1(V, x_0) & \xrightarrow[j_*]{} & \pi_1(X, x_0) = \pi_1(U \cup V, x_0). \end{array}$$

Our goal is to determine the fundamental group of the total space $X = U \cup V$ in terms of the fundamental groups of U, V, $U \cap V$ and the induced maps $\pi_1(U \cap V, x_0) \to \pi_1(U, x_0)$ and $\pi_1(U \cap V, x_0) \to \pi_1(V, x_0)$.

We start out with the following lemma:

Lemma 52.1. Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and such that $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$. If $U \cap V$ is path-connected, then the homomorphism

$$\pi_1(U, x_0) * \pi_1(V, x_0) \;\to\; \pi_1(X, x_0),$$

which is induced by the homomorphisms $\pi_1(U, x_0) \to \pi_1(X, x_0)$ and $\pi_1(V, x_0) \to \pi_1(X, x_0)$ and by Lemma 51.13 (2), is surjective.

Examples.

(1) We consider the sphere

$$X \;=\; S^2 \;=\; \{(x, y, z) \mid x^2 + y^2 + z^2 = 1\},$$

with the covering $X = U \cup V$ given by the two open subsets

$$\begin{aligned} U &= \{(x, y, z) \mid x^2 + y^2 + z^2 = 1 \text{ and } z > -\tfrac{1}{2}\}, \\ V &= \{(x, y, z) \mid x^2 + y^2 + z^2 = 1 \text{ and } z < \tfrac{1}{2}\}. \end{aligned}$$

We pick the base point $x_0 = (1, 0, 0) \subset U \cap V$. Here the intersection $U \cap V$ is path-connected, therefore we can apply Lemma 52.1. It says that we have an epimorphism

$$\pi_1(U, x_0) * \pi_1(V, x_0) \;\to\; \pi_1(S^2, x_0).$$

The subspaces U and V are homeomorphic to an open disk,[556] thus the fundamental groups are trivial. It follows that the trivial group[557] surjects onto $\pi_1(S^2, x_0)$, thus $\pi_1(S^2, x_0)$ itself is trivial. Precisely the same argument shows that $\pi_1(S^n) = 0$ for $n \geq 3$.

We had already obtained this result in the Sphere-π_1-Proposition 47.13. In fact, as we will see shortly, the proof of Lemma 52.1 has clear parallels to the proof of the Sphere-π_1-Proposition 47.13.

(2) We consider the sphere

$$X = S^1 = \{\exp(\mathrm{i}t) \mid t \in \mathbb{R}\},$$

with the covering $X = U \cup V$ given by the two open subsets

$$\begin{aligned} U &:= \{\exp(\mathrm{i}t) \mid t \in (-\tfrac{\pi}{4}, \tfrac{5\pi}{4})\} \\ V &:= \{\exp(\mathrm{i}t) \mid t \in (\tfrac{3\pi}{4}, \tfrac{9\pi}{4})\}. \end{aligned}$$

We pick the base point $x_0 = 1$. The subsets U and V are both homeomorphic to an open interval, hence $\pi_1(U, x_0) = \pi_1(V, x_0) = 0$, but of course we know from Corollary 48.18 that $\pi_1(X, x_0) \cong \mathbb{Z}$. Thus we see that $\pi_1(U, x_0) * \pi_1(V, x_0) \to \pi_1(X, x_0)$ is not an epimorphism. This is not a contradiction to Lemma 52.1, since in this example the intersection $U \cap V$ is not path-connected.

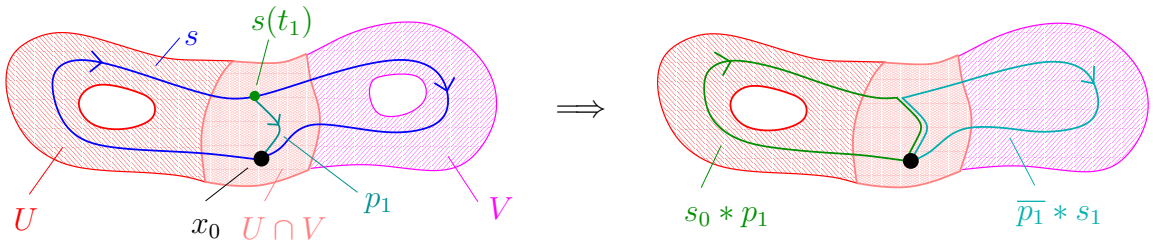
Now we turn to the proof of Lemma 52.1.

Proof of Lemma 52.1. Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and such that $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$. It suffices to prove the following claim.[558]

Claim. Every loop $s\colon [0,1] \to X = U \cup V$ in x_0 is path-homotopic to a loop which is the product of finitely many loops in (U, x_0) or in (V, x_0).

Proof. So let $s\colon [0,1] \to X = U \cup V$ be a loop in x_0. Since U and V are open we can use the Lebesgue Corollary 6.6 to find a subdivision

$$0 = t_0 < t_1 < t_2 < \ldots < t_k < t_{k+1} = 1$$



of the interval $[0,1]$ such that the image of each $s_i := s|_{[t_i, t_{i+1}]}$ lies in U or in V. The same argument as in the proof of the Sphere-π_1-Proposition 47.13 shows that we can assume that each $s(t_i)$ lies in $U \cap V$.[559] The problem is that even though the paths s_i lie in U respectively in V, they are not necessarily loops in x_0. But since $U \cap V$ is path-connected we can find for each $i \in \{1, \ldots, k\}$ a path p_i in $U \cap V$ which connects $s(t_i) \in U \cap V$ to the

[556] A homeomorphism is for example given by stereographic projection.

[557] Here we use the obvious fact that the free product of two copies of the trivial group is again the trivial group.

[558] Why does it suffice to prove this claim?

[559] Indeed, if $s(t_i)$ lies in $U \setminus V$, then $s([t_{i-1}, t_i])$ and $s([t_i, t_{i+1}])$ cannot lie in V, hence they both lie in U. This implies that $s_{([t_{i-1}, t_{i+1}])}$ lies in U, and therefore we can remove t_i from the subdivision.

base point $x_0 \in U \cap V$. Now we have the following path-homotopies:

$$\begin{array}{ccccc}
& \text{by Lemma 47.3, since } s \text{ is a reparametrization of } s_0 * \cdots * s_k & & \text{since each } p_i * \overline{p_i} \text{ is null-homotopic} & \\
s & \overset{\downarrow}{\simeq} & s_0 * \cdots * s_k & \overset{\downarrow}{\simeq} & s_0 * p_1 * \overline{p_1} * s_1 * p_2 * \overline{p_2} * s_2 * p_3 * \overline{p_3} * \ldots * \overline{p_k} * s_k \\
& & & \simeq & (\underbrace{s_0 * p_1}_{\substack{\text{loop in } (U,x_0) \\ \text{or in } (V,x_0)}}) * (\underbrace{\overline{p_1} * s_1 * p_2}_{\substack{\text{loop in } (U,x_0) \\ \text{or in } (V,x_0)}}) * (\underbrace{\overline{p_2} * s_2 * p_3}_{\substack{\text{loop in } (U,x_0) \\ \text{or in } (V,x_0)}}) * (\overline{p_3} * \ldots * (\overline{p_k} * s_k).
\end{array}$$

Thus we have shown that s is path-homotopic to a product of loops in (U, x_0) and (V, x_0).[560] ■

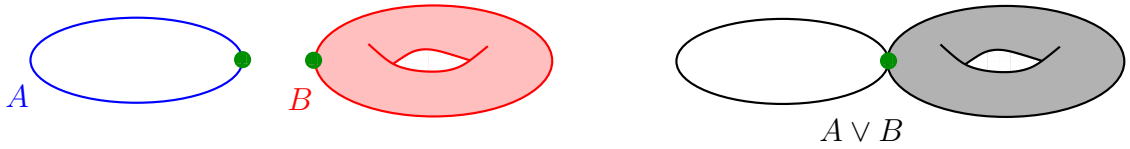
Theorem 52.2. (Seifert–van Kampen Theorem)[561] Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and with $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$. If $U \cap V$ is simply connected, then the map

$$\pi_1(U, x_0) * \pi_1(V, x_0) \;\to\; \pi_1(X, x_0)$$

that is induced by $\pi_1(U, x_0) \to \pi_1(X, x_0)$ and $\pi_1(V, x_0) \to \pi_1(X, x_0)$ and Lemma 51.13 (2), is an isomorphism.

Remark. One might wonder whether the hypothesis that $U \cap V$ is simply connected is really necessary. But this is indeed the case. For example we could take $X = S^1 \times [-1, 1]$ with $U = S^1 \times [-1, \frac{1}{2})$ and $V = S^1 \times (-\frac{1}{2}, 1]$. In this case we have $\pi_1(X) \cong \mathbb{Z}$ which is not isomorphic to the non-abelian group $\pi_1(U) * \pi_1(V) \cong \mathbb{Z} * \mathbb{Z}$.

We postpone the proof of the Seifert–van Kampen Theorem 52.2 to the next section and we first discuss several examples and applications of the theorem.
Let A and B be two topological spaces and let $a \in A$ and $b \in B$ be two points. Recall that on page 1132 we defined the wedge $A \vee B$ of A and B as



$$A \vee B \;:=\; A \sqcup B \;/\; a = b.$$

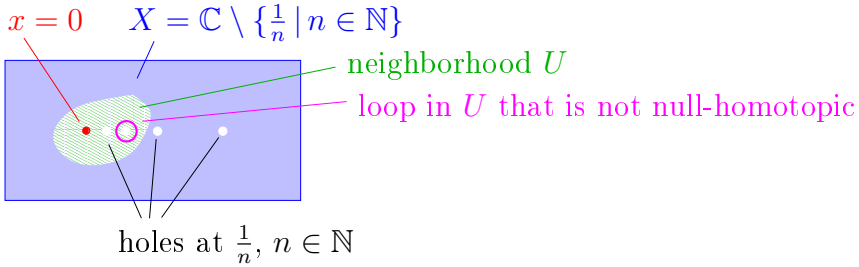
We illustrate this definition in the figure below. In the following we will often identify A and B with their respective images in $A \vee B$. Another way of thinking about the wedge of

[560] The proof of Lemma 52.1 is arguably easier to follow than the proof of the Sphere-π_1-Proposition 47.13. The reason is that in the special case the Sphere-π_1-Proposition 47.13 we introduced more notation, e.g. North Pole and South Pole, than was perhaps strictly necessary. All we really needed was that we could cover S^2 by two open simply connected subsets U and V such that $U \cap V$ is path-connected. The precise choice of U and V is irrelevant.

[561] The theorem was proved independently by Herbert Seifert (1907-1996) and Egbert van Kampen (1908-1942).

A and B is to say that the wedge $X = A \vee B$ can be decomposed into two subsets A and B such that $A \cap B$ is a point. Since $A \cap B$ is a point it is in particular simply connected. Thus it sounds like one should be able to apply the Seifert–van Kampen Theorem 52.2. This is almost correct, except that in the Seifert–van Kampen Theorem we have to deal with decompositions of a topological space X into *open* subsets. We therefore need to introduce a somewhat technical definition.

Definition. We say a point x in a topological space X is good, if the following two conditions are satisfied:



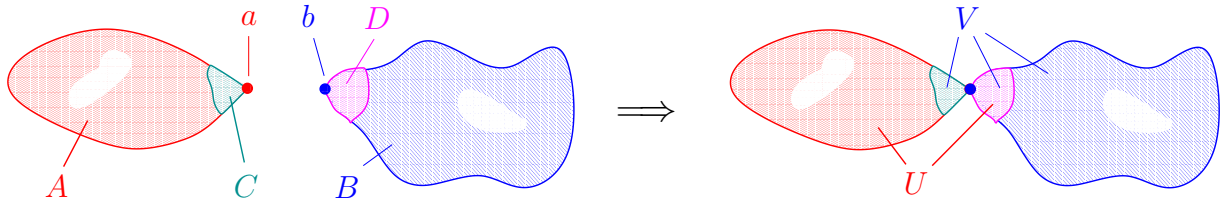
(1) $\{x\}$ is a closed subset of X and
(2) there exists an open neighborhood U of x such that x is a deformation retract of U.

Remark.

(1) If X is Hausdorff, then it we know by the Points-in-Hausdorff Space Lemma 1.15 (1) that any subset consisting of a single point is closed. Thus the first condition in the definition of a good point is satisfied "for free".
(2) What we call a "good point" is sometimes called a "non-degenerate point", see e.g. [**Lee2000**, p. 212]. On the other hand, the term "non-degenerate point" is defined in a subtly different way, see e.g. [**Spa1995**, p. 380] or [**Bre1993**, p. 435]. Also note that a point $x \in X$ is good if the pair $(X, \{x\})$ is good in the sense of [**Hat2002**, p. 114].

Examples.

(1) Let X be an n-dimensional topological manifold (e.g. a sphere). We claim that every point is good. Since X is by definition Hausdorff we only need to show that Condition (2) is always satisfied. Thus let $x \in X$. Using a chart around x one easily sees that x admits an open neighborhood that is homeomorphic to the open ball B^n or to the "open half-ball" $\{(x_1, \ldots, x_n) \in B^n \mid x_n \geq 0\}$. In both cases x is evidently a deformation retract of that open neighborhood.
(2) We consider $X = \mathbb{C} \setminus \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Morally speaking the point $x = 0$ is not good, "since any open neighborhood of 0 has non-trivial fundamental group". In Exercise 52.1 we will provide a proper proof that $x = 0$ is not a good point of X.



Proposition 52.3. (Wedge-π_1-Proposition) Let A and B be two path-connected topological spaces and let $a \in A$ and $b \in B$ be good points. Then the inclusion maps induce an isomorphism[562]

$$\pi_1(A,a) * \pi_1(B,b) \xrightarrow{\cong} \pi_1(A \vee B, a = b).$$

Remark. In the definition of a "good point" we demanded that the one-point subset given by the point is closed. Strictly speaking we do not need this fact in the proof of the Wedge-π_1-Proposition 52.3.

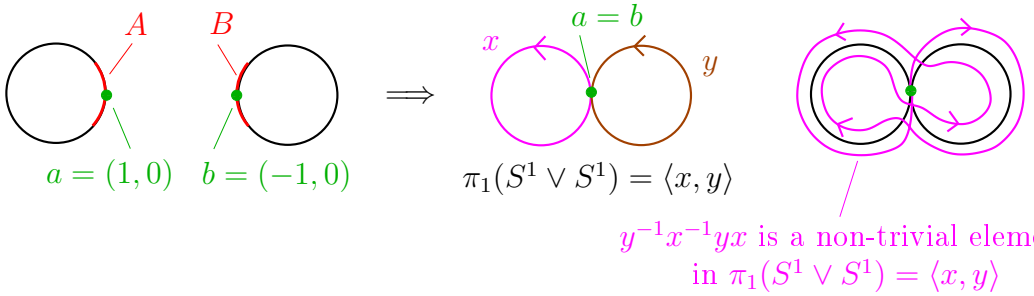
Proof. Let A and B be two path-connected topological spaces and let $a \in A$ and $b \in B$ be good points. We write $X = A \vee B$ and $x_0 = \{a, b\} \in A \vee B$. By Lemma 50.10 we can view A and B as subsets of $X = A \vee B$ in the obvious way.

We pick an open neighborhood C in A of a that deformation retracts to a. Furthermore we pick an open neighborhood D of b in B that deformation retracts to b. We consider $U := A \vee D$ and $V := B \vee C$, each viewed as subsets of $X = A \vee B$.

Now we consider the following diagram

$$\begin{array}{ccc} \pi_1(A,a) * \pi_1(B,b) & \longrightarrow & \pi_1(X,x_0) \\ \downarrow & & \downarrow \mathrm{id} \\ \pi_1(U,x_0) * \pi_1(V,x_0) & \longrightarrow & \pi_1(X,x_0). \end{array}$$

We make the following observations:



(1) The vertical and horizontal maps are all induced by the various inclusions of topological spaces. In particular the diagram commutes.
(2) It follows from the definition of the quotient topology on $A \vee B = (A \sqcup B)/\sim$ that U and V are open subsets of X.
(3) It follows from Lemma 50.13 that A is a deformation retract of $U = A \vee C$.
(4) As in (3) we see that B is a deformation retract of $V = B \vee D$.
(5) Furthermore, very similar to the argument in (3), we see that $A \cap B$ is a deformation retract of $U \cap V = C \vee D$. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2) that $U \cap V$ is simply connected.
(6) By (2) and (5) we can apply the Seifert–van Kampen Theorem 52.2 to the decomposition $A \vee B = U \cup V$ and we obtain that the bottom horizontal map of the above diagram is an isomorphism.

[562] More precisely, the two natural inclusions $A \to A \vee B$ and $B \to A \vee B$ induce homomorphisms $\pi_1(A,a) \to \pi_1(A \vee B, a = b)$ and $\pi_1(B,b) \to \pi_1(A \vee B, a = b)$. Combined with Lemma 51.13 (2) we obtain the homomorphism $\pi_1(A,a) * \pi_1(B,b) \to \pi_1(A \vee B, a = b)$.

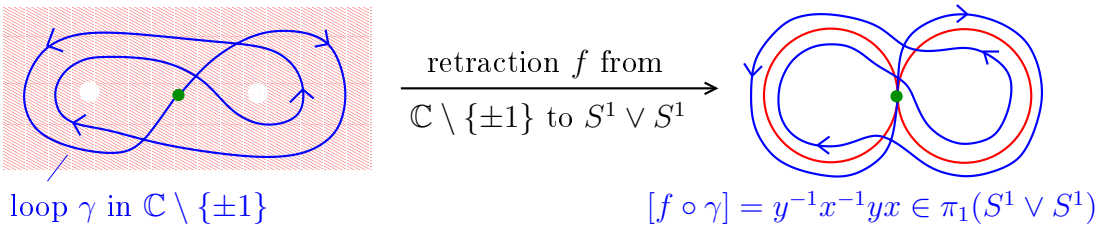
(7) It follows from (3), (4) and the Deformation Retract-Homotopy Equivalence Lemma 15.5 that the inclusions $A \to U = A \cup D$ and $B \to V = B \cup C$ are homotopy equivalences.
(8) It follows from (6) together with the Homotopy-π_1-Proposition 50.3 (2) that the two inclusion induced maps $\pi_1(A, a) \to \pi_1(U, a)$ and $\pi_1(B, b) \to \pi_1(V, b)$ are isomorphisms, which implies that the left vertical map in the above commutative diagram is an isomorphism.
(9) We deduce that the top horizontal map is, as desired, also an isomorphism. ■

Examples.

(1) We consider again the wedge $S^1 \vee S^1$ with $a = (1, 0)$ and $b = (-1, 0)$. These points are simple.[563] By Proposition 48.17 we know that $\pi_1(S^1, a) = \langle x \rangle$[564] and $\pi_1(S^1, b) = \langle y \rangle$

where x and y are represented by loops that go "once around the circle", as illustrated in the figure above. the Wedge-π_1-Proposition 52.3 says that the inclusion maps induce an isomorphism

$$\langle x, y \rangle \;=\; \langle x \rangle * \langle y \rangle \;=\; \pi_1(S^1, a) * \pi_1(S^1, b) \;\xrightarrow{\cong}\; \pi_1(S^1 \vee S^1, a = b).$$



(2) We consider the loop γ from page 1049 in $\mathbb{C} \setminus \{\pm 1\}$ that is also illustrated in the figure below. We had already pointed out on page 1134 that there exists a deformation retraction f from $\mathbb{C} \setminus \{\pm 1\}$ to the wedge of two circles that is given by

$$S^1 \vee S^1 \;=\; \underbrace{\{z \in \mathbb{C} \mid |z + 1| = 1\} \cup \{z \in \mathbb{C} \mid |z - 1| = 1\}}_{\text{two circles that meet at the origin}}.$$

We then have $f_*([\gamma]) = [f \circ \gamma] = \langle y^{-1}x^{-1}yx \rangle \in \langle x, y \rangle = \pi_1(S^1 \vee S^1)$, which is non-trivial. Thus we see that $f \circ \gamma$ is not null-homotopic in $S^1 \vee S^1$ which implies that γ is not null-homotopic in $\mathbb{C} \setminus \{\pm 1\}$.[565]

Before we continue we condense the above example into a lemma.

[563] This follows either from the general statement that any point on a topological manifold is simple, or more simply, by taking A and B to be small "intervals" around a and b.
[564] Recall that $\langle x \rangle$ denotes the free group generated by x, i.e. $\langle x \rangle = \{\dots, x^{-1}, e = x^0, x, x^2, \dots\}$.
[565] We could also have applied Seifert–van Kampen Theorem 52.2 to the covering $\mathbb{C} \setminus \{\pm 1\} = U \cup V$ where $U = \{z \in \mathbb{C} \setminus \{-1\} \mid \mathrm{Re}(z) < \frac{1}{2}\}$ and $V = \{z \in \mathbb{C} \setminus \{1\} \mid \mathrm{Re}(z) > -\frac{1}{2}\}$. Both sets U and V are open and they are homotopy equivalent to a circle.

Lemma 52.4. (Fundamental Group-Wedge-of-Circles Lemma) Let $k \in \mathbb{N}_0$. The map

$$\begin{array}{rcl} \langle x_1, \ldots, x_k \rangle & \to & \pi_1\Big(\bigvee_{i=1}^{k} S^1, *\Big) \\ x_i & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & S^1_i \\ t & \mapsto & \exp(2\pi \mathrm{i} t) \end{array}\right] \end{array}$$

that is given by

is an isomorphism.

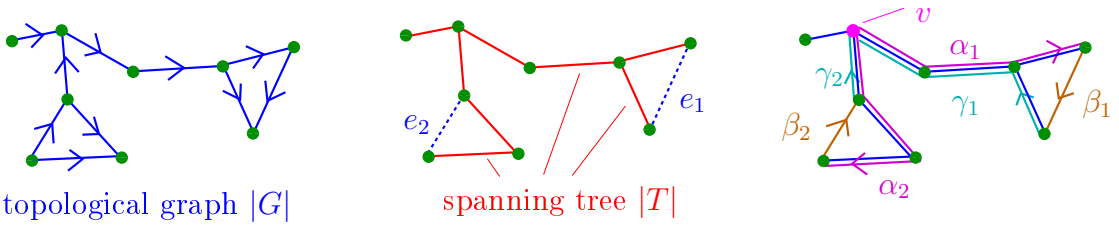
Convention. We refer to the images of $x_1, \ldots, x_k$ under the isomorphism of the Fundamental Group-Wedge-of-Circles Lemma 52.4 as the standard generating set of $\pi_1\Big(\bigvee_{i=1}^{k} S^1, *\Big)$.

Proof. Similar to the above example the lemma follows from applying the Wedge-π_1-Proposition 52.3 altogether $k-1$ times. ■

Proposition 52.5. (Fundamental Group-of-Graph Proposition)

(1) Let $G = (V, E, i, t)$ be a finite connected non-empty abstract graph and let T be a maximal tree of G. Let $e_1, \ldots, e_n$ be the edges not contained in T. We pick some $v \in V$. For $j = 1, \ldots, n$ we pick a path $\alpha_j \colon [0,1] \to |T|$ from v to $i(e_j)$, we denote by $\beta_j \colon [0,1] \to [(e_j, t)] \in |G|$ the obvious path from $i(e_j)$ to $t(e_j)$, and we pick a path $\gamma_j \colon [0,1] \to |T|$ from $t(e_j)$ to v. Then the map

$$\begin{array}{rcl} \Theta_G \colon \langle x_1, \ldots, x_n \rangle & \to & \pi_1(|G|, v) \\ x_j & \mapsto & [\alpha_j * \beta_j * \gamma_j] \end{array}$$



that is given by

is an isomorphism.

(2) Let X be a finite connected non-empty topological graph with v vertices and e edges. Then

$$\pi_1(X) \;\cong\; \text{free group on } 1 - \chi(X) = 1 + e - v \text{ generators.}$$

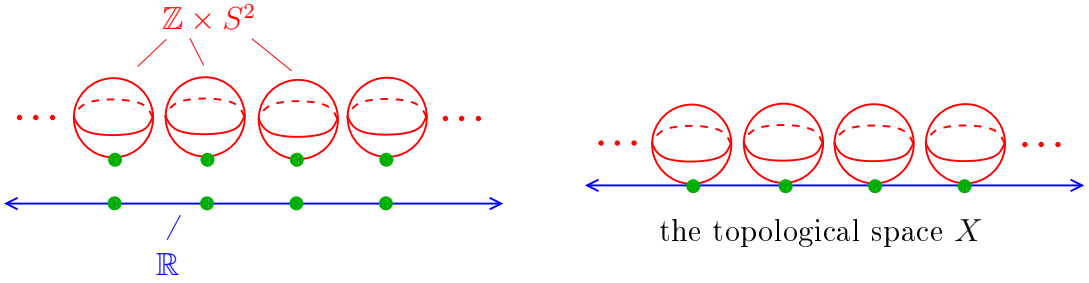
(3) Two finite connected topological graphs are homotopy equivalent if and only if they have the same Euler characteristic. ■

Proof.

(1) We consider the maps

$$\langle x_1,\dots,x_n\rangle \xrightarrow{\Theta_G} \pi_1(|G|,v) \underset{\text{isomorphism by Propositions 50.15 and 50.3 (2)}}{\to} \pi_1(|G|/|T|,v) \overset{\text{isomorphism induced by the homeomorphism on page 1133}}{\overset{\cong}{\leftarrow}} \pi_1\Big(\bigvee_{j=1}^{n} S^1_j\Big) \underset{\text{isomorphism given by the Fundamental Group-Wedge-of-Circles}}{\overset{\cong}{\leftarrow}} \langle y_1,\dots,y_n\rangle.$$

It follows fairly easily from the explicit descriptions of the various maps that for each $j\in\{1,\dots,n\}$ the images of x_j and y_j in $\pi_1(|G|/|T|,v)$ are represented by homotopic loops, in particular the images of x_j and y_j in $\pi_1(|G|/|T|,v)$ are the same. But now it follows from the above and the fact that all other maps are isomorphisms that Θ_G itself is indeed an isomorphism.



(2) Basically by definition we only need to prove the statement if $X=|G|$ is the topological realization of a finite connected non-empty abstract graph $G=(V,E,i,t)$. By the Spanning Tree Existence Proposition 7.10 (1) we know that G admits a spanning tree $T=(W,F)$. By the Spanning Tree Existence Proposition 7.10 we know that T contains all vertices of V. Furthermore, since T is a tree we know by definition of a tree that $\#W-\#F=1$. Thus it follows that there are precisely $\#E-\#F=e-(\#W-1)=e-v+1$ edges of G that are not contained in T. The desired statement now follows from (1).

(3) Let X and X' be two finite connected topological graphs. If $\chi(X)=\chi(X')$, then we already saw in Proposition 50.15 (3) that X and X' are homotopy equivalent. On the other hand, if $\chi(X)\neq\chi(X')$, then it follows from (1) together with Lemma 51.17 that X and X' are not homotopy equivalent. ■

As a last example in this section we would like to determine the fundamental group of

$$X \;=\; \big(\mathbb{R}\sqcup(\mathbb{Z}\times S^2)\big)\,/\,n\sim(n,(0,0,-1)).$$

The topological space X consists of an infinite line where to each $n\in\mathbb{Z}$ we attach a 2-dimensional sphere. The topological space X is illustrated in the figure below. Given

$k\in\mathbb{N}$ we denote by X_k the topological space that is obtained by X by restricting oneself to the interval $(-k-\frac{1}{2},k+\frac{1}{2})$, i.e.

$$X_k \;=\; \Big(\big(-k-\tfrac{1}{2},k+\tfrac{1}{2}\big)\sqcup(\{-k,\dots,k-1,k\}\times S^2)\Big)\,/\,n\sim(n,(0,0,-1)).$$

Note that X_k can be viewed as the wedge of an open interval with $2k+1$ spheres. It follows immediately from the Sphere-π_1-Proposition 47.13, the Wedge-π_1-Proposition 52.3 and a straightforward induction argument that $\pi_1(X_k)=0$ for all k. Furthermore one can easily convince oneself that the sets X_k are open. It now follows from the following lemma that $\pi_1(X)$ is also trivial.

Lemma 52.6. Let X be a path-connected topological space and let $x_0 \in X$. Furthermore let $X_k, k \in \mathbb{N}$ be a sequence of subsets of X such that the following hold:

(1) each X_k is open,
(2) each X_k is simply connected,
(3) the sequence X_k is nested, i.e. for each k we have $X_k \subset X_{k+1}$,
(4) we have $\bigcup_{k\in\mathbb{N}} X_k = X$.

Then $\pi_1(X, x_0) = 0$.

Proof. The proof of the lemma, which will make essential use of Lemma 2.12, is the content of Exercise 52.2. ∎

We conclude this section with the following generalization of the Wedge-π_1-Proposition 52.3.

Proposition 52.7. Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. Given $j \in K$ we denote by

$$i_j \colon A_j \to \bigvee_{k\in K} A_k \quad \text{respectively} \quad p_j \colon \bigvee_{k\in K} A_k \to A_j$$

the natural inclusion map respectively the natural projection . We denote by $*$ the wedge point of $\bigvee_{i\in I} X_i$. For every $n \in \mathbb{N}_0$ the projections p_k induces an isomorphism

$$\ast_{k\in K} p_{k*} \colon \pi_1\Big(\bigvee_{k\in K} A_k, *\Big) \to \text{ free product of the groups } \{\pi_1(A_k, a_k)\}_{k\in K}.$$

The inverse is induced by the inclusions i_k.

Proof. Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. We use these points to form the wedge $\bigvee_{k\in K} A_k$. Recall that the fact that a_k is good means that

(1) $\{a_k\}$ is a closed subset of A_k and
(2) that there exists an open neighborhood U_k of a_k in A_k such that a_k is a deformation retract of U_k.

The trick in the proof of Proposition 52.7 is to reduce the statement to the case of Proposition 52.7. We will show that the map

$$\ast_{k\in K} i_k \colon \ast_{k\in K} \pi_1(A_k) \to \pi_1\Big(\bigvee_{k\in K} A_k\Big)$$

is an isomorphism. (Here and throughout out we work with the obvious base points, which we suppress from the notation.) Once we will have established this fact it is straightforward to show that the inverse is given by $\ast_{k\in K} p_{k*}$.

The idea of the proof is to show that the map is a monomorphism and an epimorphism.

Claim. The map

$$\ast_{k\in K} i_k \colon \ast_{k\in K} \pi_1(A_k) \to \pi_1\Big(\bigvee_{k\in K} A_k\Big)$$

is an epimorphism.

Proof. We introduce the following notation:

(1) We write $B := \bigvee_{k\in K} A_k$ and we set $U := \bigcup_{k\in K} U_k \subset B$.

(2) Given a subset $J \subset K$ we write $B_J := \bigvee_{j\in J} A_j$ and we write $\widehat{B}_J := U \cup B_J$.

Given a finite subset $J \subset K$ we have the following commutative diagram

$$\begin{array}{ccccc}
\underset{j\in J}{*}\pi_1(A_j) & & \xrightarrow{\cong} & & \pi_1(B_J) \\
\downarrow & & & \searrow^{\cong} & \\
 & & & & \pi_1(\widehat{B}_J) \\
 & & & \swarrow & \\
\underset{k\in K}{*}\pi_1(A_k) & & \longrightarrow & & \pi_1(B).
\end{array}$$

We make the following observations and comments:

(1) The maps are either the obvious algebraic inclusion maps or they are the obvious maps induced by inclusions of topological spaces. It follows almost immediately from the definitions that the diagram commutes.
(2) Since J is finite we obtain, from applying the Wedge-π_1-Proposition 52.3 finitely many times, that the top horizontal map is an isomorphism.
(3) By Exercise 50.8 we know that B_J is a deformation retract of $\widehat{B}_J$. It follows from the Homotopy-π_1-Proposition 50.3 (2) that the top diagonal map is an isomorphism.
(4) By Exercise 50.9 we know that given any compact subset $L \subset B$ there exists a finite subset $J \subset K$ with $L \subset \widehat{B}_J$.

Now we show that the above map $\underset{k\in K}{*} i_{k*}$ is an epimorphism. So suppose we are given some $[\sigma\colon S^1 \to B] \in \pi_1(B)$. It follows from (4) there exists a finite subset $J \subset K$ such that $\sigma \in C_n(\widehat{B}_J)$. But considering the above diagram, and using the fact that the top horizontal map is an isomorphism we see that $[\sigma]$ actually lies in the image of $\underset{k\in K}{*} i_k$. ⊞

Claim. The map

$$\underset{k\in K}{*} i_k\colon \underset{k\in K}{*}\pi_1(A_k) \to \pi_1\Big(\bigvee_{k\in K} A_k\Big)$$

is a monomorphism.

Proof. We continue with the notation that we introduced in the proof of the previous claim. Given any two finite subsets $J \subset \widetilde{J} \subset K$ we have the following commutative diagram

$$\begin{array}{ccccccc}
\underset{j\in J}{*}\pi_1(A_j) & & \xrightarrow{\cong} & & \pi_1(B_J) & & \\
 & \searrow & & \swarrow & \downarrow & \searrow & \\
 & & \underset{j\in \widetilde{J}}{*}\pi_1(A_j) & \xrightarrow{\cong} & \pi_1(B_{\widetilde{J}}) & \xrightarrow{\cong} & \pi_1(\widehat{B}_{\widetilde{J}}). \\
 & \swarrow & & \searrow & & \swarrow & \\
\underset{k\in K}{*}\pi_1(A_k) & & \longrightarrow & & \pi_1(B) & &
\end{array}$$

In Exercise 52.7 we will use this diagram to show that the map $\underset{k\in K}{*} i_{k*}$ is also a monomorphism. ■

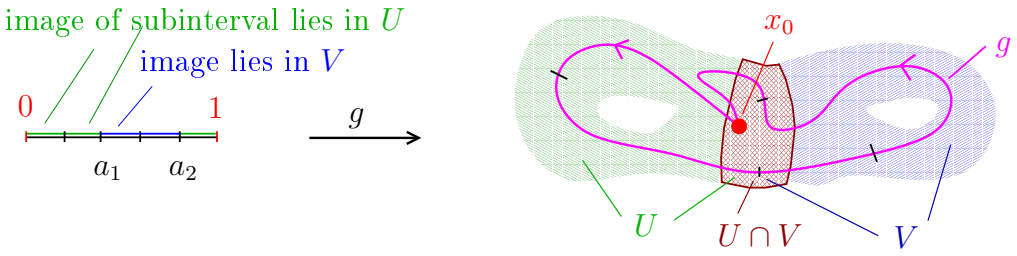
52.2. **Proof of the Seifert–van Kampen Theorem 52.2.** After this long list of applications we finally provide the proof of the Seifert–van Kampen Theorem 52.2.

Proof. Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and with $U \cap V \neq \varnothing$ such that $U \cap V$ is simply connected. We choose a base point $x_0 \in U \cap V$. We write $A := \pi_1(U, x_0)$ and $B := \pi_1(V, x_0)$. We need to show that the map

$$\Phi\colon A * B \;=\; \pi_1(U, x_0) * \pi_1(V, x_0) \;\to\; \pi_1(X, x_0)$$

that is induced by the inclusions $U \to X$ and $V \to X$ is an isomorphism. Taking into account Lemma 52.1 it suffices to show that the map is injective. To prove injectivity it is enough to show that there exists a map $\Psi\colon \pi_1(X, x_0) \to A * B$ such that $\Psi \circ \Phi = \mathrm{id}_{A*B}$. We will prove the existence of such a map Ψ in three steps:

(1) we first construct a map $\overline{\Psi}\colon \{\text{loops in } (X, x_0)\} \to A * B$,
(2) then we show that $\overline{\Psi}$ descends to a well-defined map



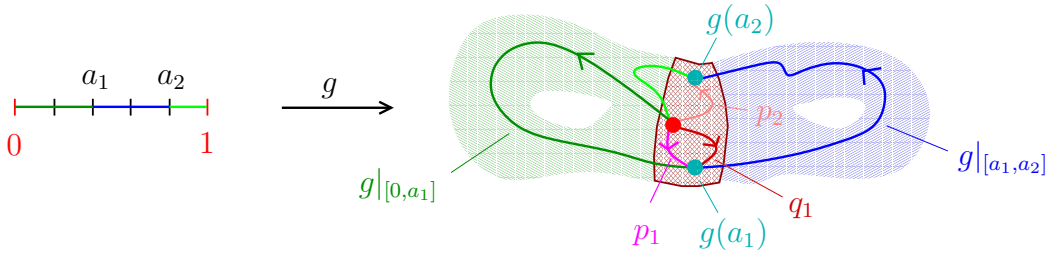
$$\begin{aligned} \Psi\colon \pi_1(X, x_0) &\to A * B \\ [g] &\mapsto \overline{\Psi}(g) \end{aligned}$$

(3) and finally we show that $\Psi \circ \Phi = \mathrm{id}_{A*B}$.

For the remainder of the proof we will identify $A*B$ with $S(A, B)/\!\sim$ using the isomorphism given by Proposition 51.18.

We start out with step (1). Let $g\colon [0,1] \to X$ be a loop in (X, x_0). We apply the Lebesgue Corollary 6.6 to the map $g\colon [0,1] \to X$ and the open cover $X = U \cup V$. We obtain an N such that for every $i \in \{0, \ldots, N-1\}$ the image of the interval $[\frac{i}{N}, \frac{i+1}{N}]$ under the map g lies in U or in V. We introduce a few definitions.

(a) We say a subinterval of $[0,1]$ can be *colored green* if the image of the subinterval under the map g lies in U and we say an interval can be *colored blue* if the image of the subinterval lies in V. Note that the image of a subinterval lies in $U \cap V$ if and only if the subinterval can be colored green as well as blue.
(b) A *coloring* is a map $\alpha\colon \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\} \to \{\text{blue}, \text{green}\}$ such that each subinterval $[i, i + \frac{1}{N}]$ can be colored by $\alpha(i)$. This definition is illustrated in the figure below.



(c) Given a coloring α we denote by $0 < a_1 < \cdots < a_{k-1} < 1$ the numbers where the coloring of the subintervals changes from one color to another. This definition is also illustrated in the figure above. Note that for each a_i the intervals $[a_i - \frac{1}{N}, a_i]$ and $[a_i, a_i + \frac{1}{N}]$ can be colored in two different colors, which implies that $g(a_i) \in U \cap V$.
(d) A *basing* for a coloring α is a collection of paths $p_1, \ldots, p_{k-1}$ in $U \cap V$ such that each path p_i goes from x_0 to $g(a_i)$.[566]

[566] Such basing exists since each $g(a_i)$ lies in $U \cap V$ and since $U \cap V$ is path-connected.

Now given a coloring α and a basing $p_1, \dots, p_{k-1}$ we define[567] [568]

$$\overline{\Psi}(g) := \big[\big[\underbrace{g|_{[0,a_1]} * \overline{p}_1}_{\substack{\text{loop in } (U,x_0) \text{ or} \\ \text{loop in } (V,x_0)}}\big], \big[\underbrace{p_1 * g|_{[a_1,a_2]} * \overline{p}_2}_{\substack{\text{loop in } (U,x_0) \text{ or} \\ \text{loop in } (V,x_0)}}\big], \dots, \big[\underbrace{p_{k-1} * g|_{[a_{k-1},1]}}_{\substack{\text{loop in } (U,x_0) \text{ or} \\ \text{loop in } (V,x_0)}}\big]\big] \in S(A,B)/{\sim} = A * B.$$

Our next goal is to prove the following claim.

Claim. The definition of $\overline{\Psi}(g)$ does not depend on any of the choices made.

Proof. We need to prove the following three statements:

(a) given N and a coloring the definition does not depend on the choice of the basings,
(b) given N the definition does not depend on the choice of the coloring,
(c) the definition does not depend on the choice of N.

We first fix a coloring α and we show that the definition of $\overline{\Psi}(g)$ does not depend on the choice of the basing. First we pick a different path q_1 from x_0 to $g(a_1)$ instead of the original path p_1. (See the above figure for an illustration.) In this case we have

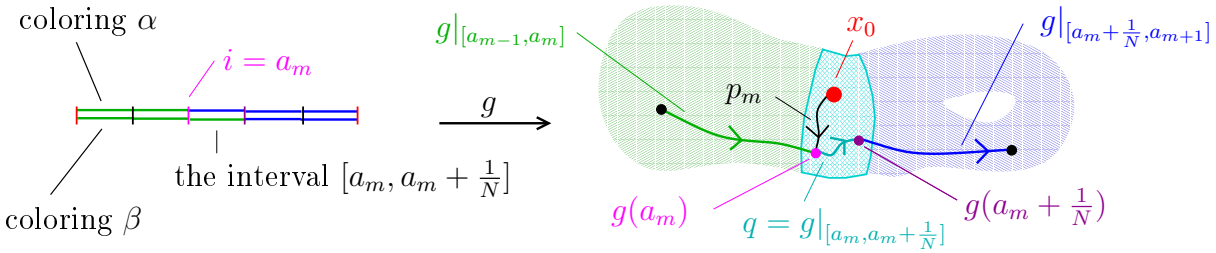
$$\begin{aligned}
&\text{definition of } \overline{\Psi}(g) \text{ using the basing } p_1, p_2, \dots, p_{k-1} \;=\\
&\quad= \big[[g|_{[0,a_1]} * \overline{p}_1],\ [p_1 * g|_{[a_1,a_2]} * \overline{p}_2], \dots,\ [p_{k-1} * g|_{[a_{k-1},1]}]\big]\\
&\quad= \big[[g|_{[0,a_1]} * \overline{p}_1 * q_1 * \overline{q}_1],\ [q_1 * \overline{q}_1 * p_1 * g|_{[a_1,a_2]} * \overline{p}_2], \dots,\ [p_{k-1} * g|_{[a_{k-1},1]}]\big]\\
&\qquad\uparrow \text{ since } q_1 * \overline{q}_1 \text{ is null-homotopic}\\
&\quad= \big[[g|_{[0,a_1]} * \overline{q}_1],\ [q_1 * g|_{[a_1,a_2]} * \overline{p}_2], \dots,\ [p_{k-1} * g|_{[a_{k-1},1]}]\big]\\
&\qquad\uparrow \overline{p}_1 * q_1 \text{ and } \overline{q}_1 * p_1 \text{ are null-homotopic since } U \cap V \text{ is simply connected}[569]\\
&\quad= \text{definition of } \overline{\Psi}(g) \text{ using the basing } q_1, p_2, \dots, p_{k-1}.
\end{aligned}$$

Precisely the same argument shows that the choices of the other paths p_i are also irrelevant. This concludes the proof of (a).

Now we show that the definition does not depend on the choice of the coloring. So suppose we have two colorings α and β. We can turn one coloring into the other by a finite sequence of color swaps of a single subinterval. Therefore it suffices to consider the case that there exists a single i where the values for $\alpha(i)$ and $\beta(i)$ differ.

[567] Each path $p_m * g|_{[a_m,a_{m+1}]} * \overline{p}_{m+1}$ is a loop in (U,x_0) or (V,x_0), so each path represents an element in $\pi_1(U,x_0)$ or $\pi_1(V,x_0)$. Thus we obtain a sequence of elements in $\pi_1(U,x_0)$ and $\pi_1(V,x_0)$. The equivalence class of this sequence defines an element in $S(A,B)/{\sim} = A * B$.

[568] This definition is almost the same as in the proof of Lemma 52.1.



[569] This is the only time that in the proof we use the hypothesis that $U \cap V$ is simply connected. In fact if one studies the argument carefully one sees that we only used that the maps $\pi_1(U \cap V, x_0) \to \pi_1(U, x_0)$ and $\pi_1(U \cap V, x_0) \to \pi_1(V, x_0)$ are trivial.

We consider the case, sketched in the figure below, with $\alpha(i) =$ blue and $\beta(i) =$ green such that the common coloring to the left is green and the common coloring to the right is blue. All other cases are dealt with in a similar way.[570]

Let $0 = a_0 < a_1 < \cdots < a_k = 1$ be the decomposition for α. We pick a basing $p_1, \ldots, p_{k-1}$ for α. There exists a unique m with $a_m = i$. The corresponding decomposition for the coloring β is given by $0 = a_0 < a_1 < \cdots < a_m + \frac{1}{N} < a_{m+1} < a_k = 1$. We write $q = g_{[a_m, a_m + \frac{1}{N}]}$. Since $[a_m, a_m + \frac{1}{N}]$ can be colored green and blue we see that q lies actually in $U \cap V$. We have

$$\begin{aligned}
&\text{definition of } \overline{\Psi}(g) \text{ using the coloring } \alpha \text{ and the basing } p_1, \ldots, p_{k-1} \;= \\
&\quad = \big[[g|_{[0,a_1]} * \overline{p}_1], \ldots, [p_{m-1} * g|_{[a_{m-1}, a_m]} * \overline{p}_m], [p_m * g|_{[a_m, a_{m+1}]} * \overline{p}_{m+1}], \ldots\big] \\
&\quad = \big[[g|_{[0,a_1]} * \overline{p}_1], \ldots, [p_{m-1} * g|_{[a_{m-1}, a_m + \frac{1}{N}]} * \overline{q} * \overline{p}_m], [p_m * q * g|_{[a_m + \frac{1}{N}, a_{m+1}]} * \overline{p}_{m+1}], \ldots\big] \\
&\qquad \uparrow \\
&\text{since } g_{[a_{m-1}, a_m]} \simeq g_{[a_{m-1}, a_m + \frac{1}{N}]} * \overline{q} \text{ and } g_{[a_m, a_m + \frac{1}{N}]} \simeq q * g_{[a_m + \frac{1}{N}, a_{m+1}]} \\
&\quad = \text{definition of } \overline{\Psi}(g) \text{ using the coloring } \beta \text{ and basing } p_1, \ldots, p_{m-1}, p_m * q, p_{m+1}, \ldots, p_{k-1}.
\end{aligned}$$

(We refer to the figure below for an illustration of the proof.) This concludes the proof of (b).

It remains to prove (c). First suppose that instead of dividing $[0,1]$ into N intervals we divide it into $m \cdot N$ intervals for some $m \in \mathbb{N}$. A coloring for the subdivision into N subintervals then also gives rise to a coloring into $m \cdot N$ subintervals, and it follows immediately from the definitions that we end up with the same element of $A * B$. Now if had chosen a different N' instead, then we can replace N and N' by $N \cdot N'$ and by the argument we just made we obtain the same element of $A * B$. This concludes the proof of (c). Summarizing, we are now done with the proof of the claim.

We turn to step (2) of the above program. We need to prove the following claim.

Claim. If $g, g' \colon [0,1] \to X$ are two path-homotopic loops in (X, x_0), then $\overline{\Psi}(g) = \overline{\Psi}(g')$.

Proof. Let $g, g' \colon [0,1] \to X$ be two path-homotopic loops in (X, x_0). We pick a path-homotopy

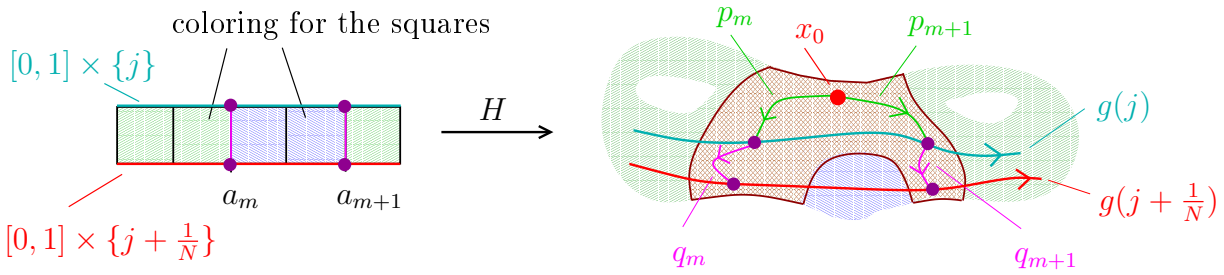
$$\begin{aligned} H \colon [0,1] \times [0,1] &\to X \\ (t, s) &\mapsto H^s(t). \end{aligned}$$

from the loop g to the loop g'. We apply the Lebesgue Corollary 6.6 to the map $H \colon [0,1] \times [0,1] \to X$ and the open cover $X = U \cup V$. We obtain an $N \in \mathbb{N}$ such that for every choice of $i, j \in \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\}$ the image of the square $[i, i + \frac{1}{N}] \times [j, j + \frac{1}{N}]$ under the map H

[570] In fact the only case which requires a slightly modified argument is that the coloring to the left and right are the same, i.e. either both are blue or both are green. We leave it to the reader to perform that argument.

lies in U or in V. Given $j \in \{0, \frac{1}{N}, \dots, 1\}$ we now define

$$\begin{array}{rcl} g(j)\colon [0,1] & \to & X \\ t & \mapsto & H^j(t) \end{array}$$



Note that each $g(j)$ is a loop in x_0 and that $g(0) = g$ and $g(1) = g'$. Therefore it suffices to show that for any $j \in \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\}$ we have $\overline{\Psi}(g(j)) = \overline{\Psi}(g(j + \frac{1}{N}))$. So let $j \in \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\}$.

As above we say that a subset of $[0,1] \times [0,1]$ can be *colored green* if the image of the subset under the map H lies in U and we say the subset can be *colored blue* if the image lies in V. We pick a map $\alpha\colon \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\} \to \{\text{blue}, \text{green}\}$ such that for each i the value $\alpha(i)$ is a color with which the square $[i, i + \frac{1}{N}] \times [\frac{j}{N}, \frac{j+1}{N}]$ can be colored. Note that α also defines a coloring for the loops $g(j)$ and $g(j + \frac{1}{N})$.

We define $0 = a_0 < a_1 < \cdots < \dots a_k = 1$ as above for the coloring α. Furthermore we pick a basing p_i, $i = 1, \dots, k-1$ for the loop $g(j)$. For $i = 0, \dots, k$ we write $q_i = H^{[j, j+\frac{1}{N}]}|_{a_i}$. Put differently, q_j connects a point on the loop $g(j)$ to the corresponding point on the loop $g(j + \frac{1}{N})$. Now we have

$$\begin{aligned} \overline{\Psi}(g(j)) &= \overline{\Psi}(g(j)) \text{ defined using the coloring } \alpha \text{ and the basing } p_1, \dots, p_{k-1} \\ &= \big[\cdots * \big[p_m * \underbrace{H^j|_{[a_m, a_{m+1}]}}_{= g(j)|_{[a_m, a_{m+1}]}} * \overline{p}_{m+1}\big] * \dots\big] \\ &= \big[\cdots * \big[p_m * q_m * \overline{q}_m * H^j|_{[a_m, a_{m+1}]} * q_{m+1} * \overline{q}_{m+1} * \overline{p}_{m+1}\big] * \dots\big] \\ &\quad \uparrow \\ &\quad \text{since each } q_m * \overline{q}_m \text{ is null-homotopic} \\ &= \big[\cdots * \big[p_m * q_m * \underbrace{H^{j+\frac{1}{N}}|_{[a_m, a_{m+1}]}}_{= g(j+\frac{1}{N})|_{[a_m, a_{m+1}]}} * \overline{q}_{m+1} * \overline{p}_{m+1}\big] * \dots\big] \\ &\quad \uparrow \\ &\quad \text{since } H \text{ restricts to path-homotopies from } \overline{q}_m * H^j|_{[a_m, a_{m+1}]} * q_{m+1} \\ &\quad \text{to } H^{j+\frac{1}{N}}|_{[a_m, a_{m+1}]} \text{ for } m = 0, \dots, k-1 \\ &= \overline{\Psi}(g(j + \tfrac{1}{N})) \text{ defined using } \alpha \text{ and the basing } p_1 * q_1, \dots, p_{k-1} * q_{k-1}. \end{aligned}$$

This last part of the proof is illustrated in the figure below. This concludes the proof of the claim and thus of part (2) of our three step program.

Summarizing we now showed that the map $\overline{\Psi}$ descends to a well-defined map

$$\begin{array}{rcl} \Psi\colon \pi_1(X, x_0) & \to & A * B \\ [g] & \mapsto & \big[\overline{\Psi}(g)\big]. \end{array}$$

It remains to prove the following claim.

Claim. We have $\Psi \circ \Phi = \mathrm{id}_{A*B}$.

Proof. So let $[y_1] \cdot \dots \cdot [y_k] \in A * B$ where $y_1, \dots, y_k$ are loops in (U, x_0) and (V, x_0). Then

$$(\Psi \circ \Phi)([y_1] \cdot \dots \cdot [y_k]) \overset{\text{definition of } \Phi\colon A*B = \pi_1(U,x_0) * \pi_1(V,x_0) \to \pi_1(X,x_0)}{=} \Psi([y_1 * \dots * y_k]) = \big[\overline{\Psi}(y_1 * \dots * y_k)\big] = [y_1 * \dots * y_k]$$
$$= [y_1] \cdot \dots \cdot [y_k].$$

by definition of $\overline{\Psi}$, where we use $N = k$ and where we can use the constant paths as basings since $y_1, \dots, y_k$ are already loops in (U, x_0) and (V, x_0)

This concludes the proof of the claim and thus also the proof of the Seifert–van Kampen Theorem 52.2 ∎

52.3. More examples: surfaces and the connected sum of smooth manifolds.

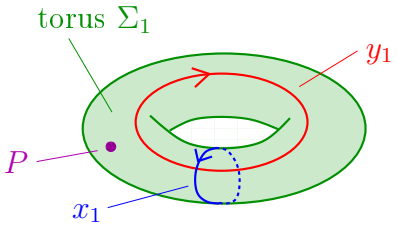
Given $g \in \mathbb{N}_0$ we denote by Σ_g the surface of genus g. In this section we first want to prove the following proposition.

Proposition 52.8. For $g \neq h$ the surface Σ_g of genus g is not homeomorphic to the surface Σ_h of genus h.

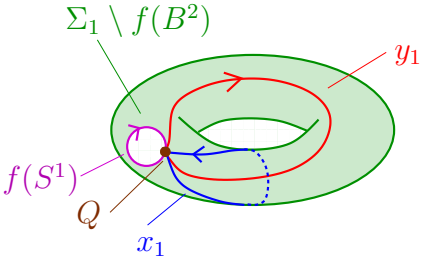
As on several earlier occasions we want to prove this result by considering what happens if we remove a point from the topological spaces.

Lemma 52.9. Let $g \in \mathbb{N}_0$. We denote by Σ_g the surface of genus g.

(1) For any point P the complement $\Sigma_g \setminus \{P\}$ is homotopy equivalent to the wedge of $2g$ circles. In particular



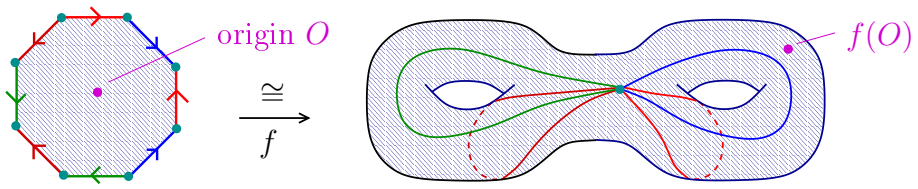
$$\pi_1(\Sigma_g \setminus \{P\}) \cong \langle x_1, y_1, \dots, x_g, y_g \rangle.$$



(2) Let $f\colon \overline{B}^2 \to \Sigma_g$ be a smooth embedding. The complement $\Sigma_g \setminus f(B^2)$ is homotopy equivalent to the wedge of $2g$ circles. Furthermore, if $Q \in f(S^1)$ is a point, then there exists an isomorphism

$$\begin{array}{rcl} \pi_1(\Sigma_g \setminus f(B^2), Q) & \overset{\cong}{\to} & \langle x_1, y_1, \dots, x_g, y_g \rangle \\ [f\colon S^1 \to \Sigma_g \setminus f(B^2)] & \mapsto & [x_1, y_1] \cdot \dots \cdot [x_g, y_g] \end{array}$$

with



where $[x_i, y_i] := x_i y_i x_i^{-1} y_i^{-1}$ is the commutator of x_i and y_i. In particular the map $f\colon S^1 \to \Sigma_g \setminus f(B^2)$ represents a non-trivial element in $\pi_1(\Sigma_g \setminus f(B^2), Q)$.

Proof of Lemma 52.9. We prove the lemma for the surface Σ of genus 2. The proof for $g \geq 3$ is almost identical. So let $\Sigma = E_8/\sim$ as sketched in the figure below.

(1) We denote by O the origin in $E_8 \subset \mathbb{C}$. We first show that $\Sigma \setminus \{O\}$ is homotopy equivalent to the wedge of 4 circles.

Claim. There exists a deformation retraction from $\Sigma \setminus \{O\} = (E_8 \setminus \{O\})/\sim$ to the subset $\partial E_8/\sim$.

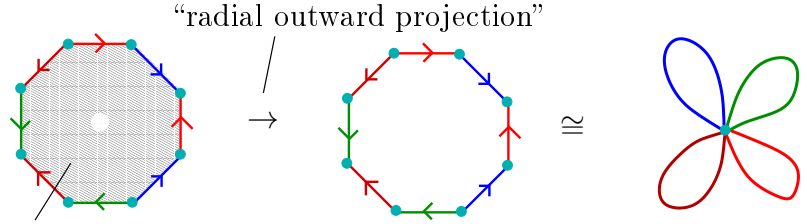
Proof. First we consider the map[571][572]

$$\begin{array}{rcl} r\colon E_8 \setminus \{O\} & \to & \partial E_8 \\ r \cdot \exp(\mathrm{i}\varphi) & \mapsto & \text{unique point } s\exp(\mathrm{i}\varphi) \text{ on } \partial E_8. \end{array}$$

This map "projects points radially outward towards the boundary". The deformation retraction is now given by "pushing outward radially", i.e. it is given by the map

$$\begin{array}{rcl} ((E_8 \setminus \{O\})/\sim) \times [0,1] & \to & (E_8 \setminus \{O\})/\sim \\ ([P], t) & \mapsto & [P \cdot (1-t) + r(P) \cdot t]. \end{array}$$ ⊞

Claim. The topological space $\partial E_8/\sim$ is homeomorphic to the wedge of 4 circles.



Proof. A homeomorphism is given by sending the point on $\partial E_8/\sim$ that corresponds to the vertices to the common point of the four circles, and by sending the edges that get identified to the same circle. We refer to the figure below for an illustration. We leave it to the reader to write down the proof in detail.

The two claims put together show that $\Sigma \setminus \{O\}$ is homotopy equivalent to the wedge of 4 circles. Now we obtain that

$$\pi_1(\Sigma_2 \setminus \{P\}) \underset{\uparrow}{\cong} \pi_1(\text{wedge of 4 circles}) \underset{\uparrow}{\cong} \langle x_1, y_1, x_2, y_2 \rangle.$$

Fundamental Group-Homotopy Proposition 50.3 (2) — by Lemma 52.4

Now let P be some other point on Σ. By Proposition 36.4 there exists a homeomorphism $\Phi\colon \Sigma \to \Sigma$ with $\Phi(P) = O$.[573] This shows that $\Sigma \setminus \{P\}$ is homeomorphic to $\Sigma \setminus \{O\}$. We can thus appeal to the above calculation to get the desired result.

(2) The proof of this statement is very similar to the proof of the first statement. First remove an open disk centered at O and we perform almost the same calculation as above. One easily sees that the boundary curve corresponds to the product of

[571] Note that this map cannot be extended continuously to O.

[572] Here we use polar coordinates, i.e. r, s are positive real numbers.

[573] Note that here we use Proposition 19.18 which says that Σ is a smooth manifold with empty boundary.

commutators. It follows from the Smooth Ball Embedding Theorem 37.8 that the same calculation also works for any other disk. We leave the details to the reader. ■

Now we can turn to the proof of Proposition 52.8.

Proof of Proposition 52.8. Let S and T be two surfaces of genus g and h. Suppose that there exists a homeomorphism $f\colon S \to T$. Pick a point $P \in S$. We write $Q = f(P)$. The homeomorphism f restricts to a homeomorphism $f\colon S \setminus \{P\} \to T \setminus \{Q\}$. It now follows that

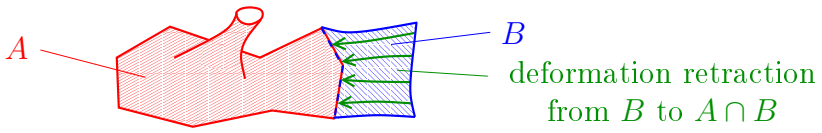
$$\langle x_1, \dots, x_{2g} \rangle \underset{\text{Lemma 52.9 (1)}}{\cong} \pi_1(S \setminus \{P\}) \xrightarrow[f_*]{\cong} \pi_1(T \setminus \{Q\}) \underset{\text{Lemma 52.9 (1)}}{\cong} \langle y_1, \dots, y_{2h} \rangle.$$

We obtain from Lemma 51.17 that $g = h$. ■

For many applications the following theorem, which is a variation on the Seifert–van Kampen Theorem 52.2, is very useful.

Theorem 52.10. (Seifert–van Kampen Theorem for topological manifolds) Let M be an m-dimensional topological manifold and let $R, S \subset M$ be two m-dimensional submanifolds such that the following hold:

(1) $M = R \cup S$,
(2) $R \cap S$ is a component of ∂R and it is a component of ∂S,
(3) $R \cap S$ is non-empty and simply connected,
(4) R and S are closed subsets of M. (Note that by the Compact-Closed Lemma 1.21 (2) this condition is satisfied if R and S are compact.)



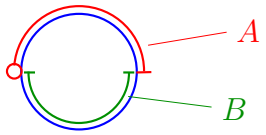
Then for any base point $x_0 \in R \cap S$ the inclusion induced map

$$\pi_1(R, x_0) * \pi_1(S, x_0) \;\to\; \pi_1(M, x_0)$$

is an isomorphism.

We will of course prove Theorem 52.10 by reducing it to Theorem 52.2. As we will see, the proof is very similar to the proof of the Wedge-π_1-Proposition 52.3 where we determined the fundamental group of a wedge of two spaces.
The proof of Theorem 52.10 relies on the following lemma which we will use on several occasions.

Lemma 52.11. Let X be a topological space. Furthermore let A and B be two subsets with $X = A \cup B$. If $A \cap B$ is a deformation retract of B and if A and B are closed subsets of X, then A is a deformation retract of X.



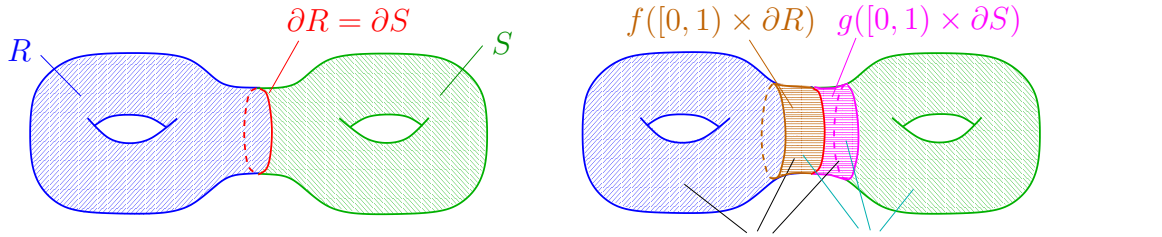
Proof. Lemma 52.11 can also be viewed as a consequence of Lemma 5.36 and the slightly scary the Homotopy Pushout Lemma 14.9. Since our situation is fairly straightforward we also give a direct, fairly elementary proof.

We pick a deformation retraction $F\colon B \times [0,1] \to B$ from B to $A \cap B$. We consider the map

$$\begin{array}{rcl} G\colon X\times[0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } x\in A, \\ F(x,t), & \text{if } x\in B. \end{cases} \end{array}$$

Since A and B are closed subsets of X we obtain from the Homotopy Stacking Lemma 14.3 that G is continuous. It is now clear that G is the desired deformation retraction from X to A. ■

Remark. On two occasions we are going to struggle a lit bit to verify the hypothesis of Lemma 52.11 that A and B need to be closed. Thus it is good to remind ourselves of the fact that hypothesis are usually added not to vex the reader but since they are necessary. For example, let us consider the situation shown in the figure below. Here $A\cap B$ is a deformation retract of B, but it should be pretty clear that A is not a deformation retract of $A\cup B = S^1$.



Proof of Theorem 52.10. Let M be an m-dimensional topological manifold and let $R, S\subset M$ be two m-dimensional submanifolds such that the following hold:

(1) $M = R\cup S$,
(2) $R\cap S$ is a union of components of ∂R and it is a union of components of ∂S,
(3) $R\cap S$ is simply connected,
(4) R and S are closed subsets of M.

We pick a base point[574] $x_0\in R\cap S$. Furthermore we pick maps $f\colon [0,1]\times\partial R\to R$ and $g\colon [0,1]\times\partial S\to S$ that are provided by the Smooth Collar Neighborhood Theorem 75.5[575] It follows from (2) that we can set

$$U := R\cup\underbrace{[0,1)\times g((R\cap S))}_{\subset[0,1)\times S} \quad\text{and}\quad V := S\cup\underbrace{[0,1)\times f((R\cap S))}_{\subset[0,1)\times R}.$$

We consider the following diagram

$$\begin{array}{ccc} \pi_1(R,x_0)*\pi_1(S,x_0) & \longrightarrow & \pi_1(M,x_0) \\ \downarrow & & \downarrow\mathrm{id} \\ \pi_1(U,x_0)*\pi_1(V,x_0) & \longrightarrow & \pi_1(M,x_0). \end{array}$$

[574]Recall that being simply connected entails being non-empty, hence such a point exists.
[575]If we are dealing with a smooth manifold we can also use the Smooth Collar Neighborhood Theorem 28.3.

The following steps are similar to the ones we performed in the proof of the Wedge-π_1-Proposition 52.3.

(1) Since the vertical maps are induced by inclusions we see that the diagram commutes.
(2) We claim that U is an open subset of $M = R \cup S$. Since R and S are by our hypothesis (4) closed subsets of M we obtain from Lemma 1.8 (2a) it suffices to show that $U \cap R$ is open in R and that $U \cap S$ is open in S. Evidently $U \cap R = R$ is open in R. Furthermore, $U \cap S = g([0,1] \times (R \cap S))$ is an open subset of S by (2) and the Basics-of-Collars Lemma 28.4.
(3) We want to use Lemma 52.11 to show that R is a deformation retract of U. We need to verify that the hypotheses of Lemma 52.11 are satisfied, i.e. we need to show that R and $g([0,1) \times (R \cap S))$ are closed subsets of U. By our hypothesis R and S are closed subsets of M. It follows from the Neighborhood Openness Criterion 1.5 (2) that $R = R \cap U$ and $g([0,1] \times (R \cap S)) = S \cap U$ are closed subsets of U.
(4) The obvious analogues of (2) and (3) hold for V and S.
(5) We obtain from (2), (3), (4) and the Homotopy-π_1-Proposition 50.3 (2) that the vertical map on the left is an isomorphism.
(6) Similar to (3) one can show that $R \cap S$ is a deformation retract of $U \cap V$. It follows from (3), the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2) that $U \cap V$ is simply connected.
(7) It follows from the Seifert–van Kampen Theorem 52.2 that the bottom horizontal map of the above commutative diagram is an isomorphism.
(8) Since the vertical maps are isomorphisms we see that the top horizontal map is also an isomorphism. ■

We conclude this section by considering the connected sum of two smooth manifolds of dimension ≥ 3. More precisely, we have the following proposition:

Proposition 52.12. (Connected Sum-π_1-Proposition) Let $n \geq 3$ and let M and M' be two oriented connected non-empty n-dimensional smooth manifolds. Then[576]

$$\pi_1(M \# M') \ \cong \ \pi_1(M) * \pi_1(M').$$

Examples.

(1) Let p, q be two coprime integers and let r, s be another two coprime integers. We can then consider the lens spaces $L(p,q)$ and $L(r,s)$. It follows from the Connected Sum-π_1-Proposition 52.12 and Corollary 48.18 that

$$\pi_1(L(p,q) \# L(r,s)) \ \cong \ \mathbb{Z}_p * \mathbb{Z}_r.$$

It follows for example from this calculation of fundamental groups, from Lemma 51.21 and from the Grushko Decomposition Theorem 51.22 that the two topological spaces $L(3,1) \# L(35,1)$ and $L(5,1) \# L(21,1)$ are not homeomorphic.
(2) Let $n \geq 3$ and let M and N be two oriented connected n-dimensional smooth manifolds. We denote by $-N$ the same smooth manifold as N but with the opposite orientation. It follows from the Connected Sum-π_1-Proposition 52.12 that $\pi_1(M \# N) \cong \pi_1(M \# (-N))$.

[576]Note that by the Connected Sum-Proposition **??** (3) we know that $M \# M'$ is also connected, thus we do not need to worry about base points.

Proof of the Connected Sum-π_1-Proposition 52.12. Let M and M' be two oriented connected non-empty n-dimensional smooth manifolds and let $\varphi\colon \overline{B}^n \to M$ and $\varphi'\colon \overline{B}^n \to M'$ be two smooth embeddings where φ is orientation-preserving and φ' is orientation-reversing. Recall that the connected sum of M and M' is defined as

$$M\#M' := \big(\underbrace{(M \setminus \varphi(B^n))}_{=:X} \sqcup \underbrace{(M' \setminus \varphi'(B^n))}_{=:X'}\big) / \varphi(P) = \varphi'(P) \text{ for } P \in S^{n-1}.$$

We pick a base point x_0 that lies in the intersection of the images of X and X' in $M\#M'$.

Claim. The inclusion induced maps $\pi_1(X, x_0) \to \pi_1(M, x_0)$ and $\pi_1(X', x_0) \to \pi_1(M', x_0)$ are isomorphisms.

Proof. We show that the inclusion induced map $\pi_1(X, x_0) \to \pi_1(M, x_0)$ is an isomorphism. We write $Y = \varphi(\overline{B}^n)$. It follows from the Smooth Embedding Theorem 24.10 that X and Y are n-dimensional submanifolds of M. Note that $X \cup Y = M$ and that $X \cap Y = \partial Y \cong S^{n-1}$. Since $n \geq 3$ we obtain from the Sphere-π_1-Proposition 47.13 that $X \cap Y$ is simply connected. We obtain that

$$\pi_1(X, x_0) \xrightarrow[\uparrow]{\cong} \pi_1(X, x_0) * \pi_1\big(\overline{B}^n, x_0\big) \xrightarrow[\uparrow]{\cong} \pi_1(M, x_0).$$

since $\pi_1\big(\overline{B}^n, x_0\big) = \{e\}$ — Seifert–van Kampen Theorem 52.10

Since the horizontal maps are induced by the inclusion maps we see that the inclusion induced map $\pi_1(X, x_0) \to \pi_1(M, x_0)$ is an isomorphism. The same way we can show that the inclusion induced map $\pi_1(X', x_0) \to \pi_1(M', x_0)$ is an isomorphism. ⊞

Now we see that[577]

$$\pi_1(M\#M', x_0) \xleftarrow[\uparrow]{\cong} \pi_1(X, x_0) * \pi_1(X', x_0) \xrightarrow[\uparrow]{\cong} \pi_1(M, x_0) * \pi_1(M', x_0).$$

by Theorem 52.10, since $X \cap X' \cong S^{n-1}$ is simply connected — above claim

■

Remark. We cannot apply the Seifert–van Kampen Theorem 52.2 to the connected sum of two surfaces, since in this case the fundamental group of the overlap $R \cap R'$ in the proof of the Connected Sum-π_1-Proposition 52.12 is not simply connected. In particular we cannot use this approach to determine the fundamental group of the surface of genus 2, which by the figure on page **??** is the connected sum of two tori. Our next goal is to formulate and prove a generalization of the Seifert–van Kampen Theorem 52.2 which will allow us to determine the fundamental group of the surface of genus g for $g \geq 2$.

Exercises for Chapter 52.

Exercise 52.1. We consider $X = \mathbb{C} \setminus \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Show that the point $x = 0$ is not good, i.e. show that there does not exist an open neighborhood U of $x = 0$ such that $x = 0$ is a deformation retract of U.

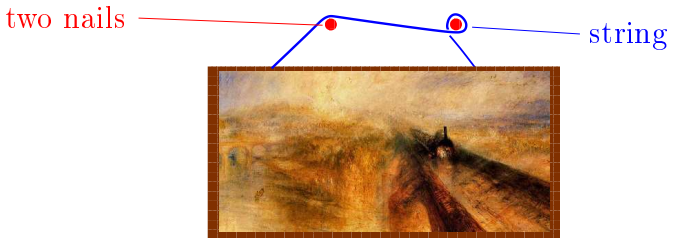
Exercise 52.2.

[577] Here the directions of the arrow indicate in which direction the obvious inclusion induced maps point.

(1) Let X be a path-connected topological space and let $x_0 \in X$. Furthermore let $X_k, k \in \mathbb{N}$ be a sequence of subsets of X such that the following hold:
   (a) each X_k is open,
   (b) each X_k is simply connected,
   (c) the sequence X_k is nested, i.e. for each k we have $X_k \subset X_{k+1}$,
   (d) we have $\bigcup_{k\in\mathbb{N}} X_k = X$.

   Show that $\pi_1(X, x_0) = 0$.
   Hint. Use Lemma 2.12.
(2) Does the conclusion of (1) also hold if the sets X_k are not open?

Exercise 52.3. Let M be a *topological* manifold of dimension $n \geq 3$. Let P be a point and let $x_0 \in M \setminus \{P\}$ be a base point. Show that the inclusion induced map



$$\pi_1(M \setminus \{P\}, x_0) \;\to\; \pi_1(M, x_0)$$

is an isomorphism.

Exercise 52.4.

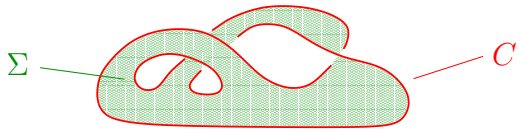
(a) How can one hang a painting with two nails provided, such that if one removes either of the two nails, the painting falls down?
(b) What is a solution to (a) if we use three nails instead of two nails?

Hint. What does this have to do with free groups?

Exercise 52.5. Show that condition (4) in the statement of the Seifert–van Kampen Theorem 52.10 for smooth manifolds cannot be dropped. More precisely, give an example of an m-dimensional smooth manifold and m-dimensional submanifolds R and S such that conditions (1), (2) and (3) are satisfied, but such that $\pi_1(R, x_0) * \pi_1(S, x_0)$ is not isomorphic to $\pi_1(M, x_0)$.
Hint. The dimension m does not have to be taken particularly large.

Exercise 52.6. We consider the two topological manifolds X and Y that are shown in the figure below. Show that X and Y are not homeomorphic.
Remark. As a smooth manifold X is orientable and Y is non-orientable. But as of right now we do not know whether orientability is preserved under homeomorphisms.
Hint. You could use Proposition 50.7 and consider the interaction between the topological manifolds and their boundaries.

Exercise 52.7. In the proof of Proposition 52.7, given on page 1176, show that the map



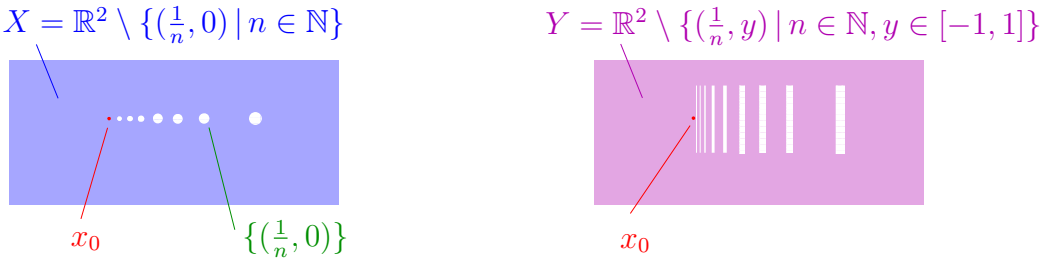
$$\ast_{k\in K} i_{k*} \colon \ast_{k\in K} \pi_1(A_k) \;\to\; \pi_1\Big(\bigvee_{k\in K} A_k\Big)$$

is a monomorphism.
Hint. Consider the commutative diagram shown on page 1177.

Exercise 52.8. Let Σ be the 2-dimensional smooth manifold that is shown in the figure below. We denote by C the boundary of Σ.

(a) What is the homeomorphism type of the topological space that we obtain from gluing a disk $\overline{B}^2$ to Σ along the boundary C?
(b) Is C a retract of Σ?

Exercise 52.9.



(a) Let $n \geq 3$ and furthermore let $K \subset \mathbb{R}^n$ be a compact subset. We view K also as a subset of $S^n = \mathbb{R}^n \cup \{\infty\}$. Let $x_0 \in \mathbb{R}^n \setminus K$. Show that the inclusion induced map $\pi_1(\mathbb{R}^n \setminus K, x_0) \to \pi_1(S^n \setminus K, x_0)$ is an isomorphism.
(b) Does the conclusion of (a) also hold for $n = 2$?
(c) Does the conclusion of (c) also hold for non-compact subsets of $\mathbb{R}^n$?

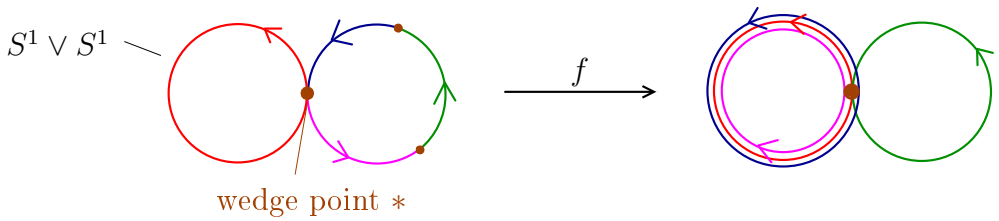
Exercise 52.10. We consider the two topological spaces

$$X = \mathbb{R}^2 \setminus \{(\tfrac{1}{n}, 0) \,|\, n \in \mathbb{N}\} \text{ and } \quad \text{and } Y = \mathbb{R}^2 \setminus \{(\tfrac{1}{n}, y) \,|\, n \in \mathbb{N}, y \in [-1, 1]\}.$$

We write $x_0 = (0, 0)$. We refer to the figure below for an illustration.

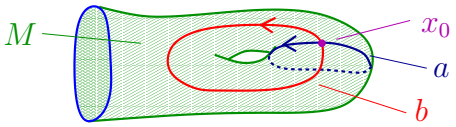
(a) Show that $\pi_1(X, x_0)$ is uncountable.
Hint. For $n \in \mathbb{N}$ we write $Z_n := \mathbb{R}^2 \setminus \{\frac{1}{n}, 0\}$ and we denote by $f_n \colon X \to Z_n$ the inclusion map. Use the induced maps $f_{n*} \colon \pi_1(X, x_0) \to \pi_1(Z_n, x_0) \cong \mathbb{Z}$ to find a homomorphism from $\pi_1(X, x_0)$ to a group such that the image is uncountable.
(b) Show that $\pi_1(Y, x_0)$ is countable.
Hint. Use Exercise 2.44 to find a monomorphism from $\pi_1(Y, x_0)$ into a countable group.

Exercise 52.11. Show that given any $k \in \mathbb{N}$ and given any $n \geq 3$ there exists a closed orientable connected n-dimensional smooth manifold M such that $\pi_1(M) \cong \langle x_1, \ldots, x_k \rangle$.



Exercise 52.12. We consider the wedge $S^1 \vee S^1$ of two circles and we denote by $*$ the wedge point. We consider the map $f\colon S^1 \vee S^1 \to S^1 \vee S^1$ that is shown in the figure below.

(a) Show that f is a homotopy equivalence.
(b) Show that every homeomorphism of $S^1 \vee S^1$ preserves the wedge point $*$.
(c) Determine



$$\{\varphi \in \mathrm{Aut}(\pi_1(S^1 \vee S^1, *)) \mid \text{ there exists a homeomorphism } g \text{ with } \varphi = g_*\}.$$

(d) Show that f is not homotopic to a self-homeomorphism of $S^1 \vee S^1$.

Remark. In Proposition **??** we will show that there exist self-homotopy equivalences of smooth manifolds that are not homotopic to homeomorphisms.

Exercise 52.13. We consider 2-dimensional smooth manifold M and the two oriented loops a and b in the point $x_0 \in M$ that are shown in the figure below. Sketch an *embedded* loop $g\colon S^1 \to M$ that represents the commutator $[a, b] \in \pi_1(M, x_0)$.

Exercise 52.14. Let $g \in \mathbb{N}$. We denote by Σ_g the surface of genus g.

(a) Does there exist a smooth map $\Sigma_g \to S^2$ that is a local diffeomorphism?
(b) Let M be the smooth manifold that we obtain from removing a single point from the surface of genus g. Does there exist a smooth map $M \to S^2$ that is a local diffeomorphism?

53. Presentations of groups and amalgamated products

We have now made some progress, for example we have shown that surfaces of different genus are not homeomorphic. But this proof is perhaps slightly unsatisfactory in so far as we used the trick of removing a point, instead of dealing directly with the fundamental groups of surfaces.

In the next section we will cover the generalized Seifert–van Kampen Theorem. It will allow us to compute many more fundamental groups. In particular we will determine the fundamental groups of surfaces and knot complements.
Before we can state the generalized Seifert–van Kampen Theorem we need to introduce more concepts from group theory. We will do so in this chapter.

53.1. **Basic definitions in group theory.** We recall a few basic definitions from group theory.

Definition. Let G be a group.

(1) A subgroup H is called normal if for every $g \in G$ we have $g^{-1}Hg = H$. If $H \subset G$ is normal, then we often write $H \lhd G$. If $\{H_i\}_{i\in I}$ is a family of normal subgroups of G, then it is straightforward to see that the intersection $\bigcap_{i\in I} H_i$ is again a normal subgroup of G.

(2) Let H be a subgroup of G. The subgroup H defines an equivalence relation on G by defining $g \sim \widetilde{g}$ if there exists an $h \in H$ with $gh = \widetilde{g}$. Put differently, we have $g \sim \widetilde{g}$ if $\widetilde{g}^{-1}g \in H$. (Note that the equivalence classes are precisely the sets of the form $gH = \{gh \mid h \in H\}$ for some $g \in G$.) We denote the set of equivalence classes by G/H.

Remark. Let H be a normal subgroup of G.

(1) For any $h \in H$ and $a, b \in G$ we have

$$ahbH \;=\; ab\cdot \underbrace{b^{-1}hb}_{\text{in } H \text{ since } H \text{ is normal}} H \;=\; abH.$$

(2) If $aH = bH$, then for any $c, d \in G$ we have

$$cadH \;=\; cb\underbrace{(b^{-1}a)}_{\in H}dH \;\underset{\text{above remark (1)}}{=}\; cbdH.$$

Now we will see that the group structure on G descends to a group structure on G/H. More precisely, given aH and bH we set

$$aH \cdot bH \;:=\; abH.$$

It follows immediately from the above remark (1) that this definition does not depend on the representatives a and b. It is now straightforward to see that this defines indeed a group structure on G/H. The following lemma plays the same role as the Topological-Quotient Proposition 5.15 (1b) does for topological spaces.

Lemma 53.1. Let G be a group and let H be a normal subgroup. Let $\varphi\colon G \to \Gamma$ be a group homomorphism with the property that $H \subset \ker(\varphi)$. Then there exists a unique

homomorphism $\psi\colon G/H \to \Gamma$ such that the following diagram commutes

$$\begin{array}{ccc} G & \longrightarrow & G/H \\ & \searrow^{\varphi} & \downarrow{\scriptstyle \psi} \\ & & \Gamma. \end{array}$$

Proof. For $gH \in G/H$ we put $\psi(gH) := \varphi(g)$. Since $H \subset \ker(\varphi)$ this definition is independent of the choice of the representatives g.[578] It is straightforward to verify that ψ is a homomorphism and that it is uniquely determined by the desired property. ∎

53.2. Presentations of groups.

Definition. Let G be a group and let $A \subset G$ be a subset. We define

$$\text{subgroup of } G \text{ generated by } A \;:=\; \langle A \rangle \;:=\; \bigcap_{\substack{A \subset H \subset G \\ H \text{ subgroup}}} H,$$

i.e. $\langle A \rangle$ is the intersection of all subgroups H of G which contain A. This is again a subgroup of G, namely the smallest[579] subgroup of G which contains A. Similarly we define

$$\text{subgroup of } G \text{ normally generated by } A \;:=\; \langle\langle A \rangle\rangle \;:=\; \bigcap_{A \subset H \lhd G} H,$$

i.e. $\langle\langle A \rangle\rangle$ is the intersection of all normal subgroups H of G which contain A. This is again a normal subgroup of G, namely the smallest normal subgroup of G which contains A.

The following lemma follows immediately from the definitions and from the fact that in an abelian group every subgroup is normal.

Lemma 53.2. Let G be a group and let $A \subset G$ be a subset.

(1) If A is a subgroup, then $\langle A \rangle = A$.
(2) If A is a normal subgroup, then $\langle\langle A \rangle\rangle = A$.
(3) If G is abelian, then $\langle\langle A \rangle\rangle = \langle A \rangle$.
(4) For any $B \subset G$ with $A \subset B \subset \langle\langle A \rangle\rangle$ we have $\langle\langle B \rangle\rangle = \langle\langle A \rangle\rangle$.
(5) Suppose that for each $a \in A$ we are given $g_a \in A$. Then $\langle\langle \{g_a a g_a^{-1}\}_{a \in A} \rangle\rangle = \langle\langle A \rangle\rangle$.

The following lemma gives a more explicit description of $\langle A \rangle$ and $\langle\langle A \rangle\rangle$.

Lemma 53.3. Let G be a group and let $A \subset G$ be a subset.

(1) Then $\langle A \rangle$ equals the set of all elements of G which can be written as products of elements in A and their inverses, i.e.

$$\langle A \rangle \;=\; \left\{ a_1^{\epsilon_1} \cdot \dots \cdot a_k^{\epsilon_k} \mid a_1, \dots, a_k \in A \text{ and } \epsilon_1, \dots, \epsilon_k \in \{-1, 1\} \right\}.$$

(2) The subset $\langle\langle A \rangle\rangle$ equals the set of all elements of G which can be written as products of conjugates of elements in A and their inverses, i.e.

$$\langle\langle A \rangle\rangle = \left\{ g_1 a_1^{\epsilon_1} g_1^{-1} \dots g_k a_k^{\epsilon_k} g_k^{-1} \mid a_1, \dots, a_k \in A, g_1 \dots, g_k \in G \text{ and } \epsilon_1, \dots, \epsilon_k \in \{-1, 1\} \right\}.$$

[578] Indeed, if $gH = \widetilde{g}H$, then $g = \widetilde{g}h$ for some $h \in H$, therefore $\varphi(g) = \varphi(\widetilde{g}h) = \varphi(\widetilde{g}) \cdot \varphi(h) = \varphi(\widetilde{g})$.

[579] Here "smallest" means that if B is another subgroup that contains A, then $\langle A \rangle \subset B$. This statement is obvious, since B appears in the definition of $\langle A \rangle$ as one of the H's.

Example. On page 1074 we introduced a subgroup of the group H of all self-homeomorphisms of $\mathbb{R}^2$ that was generated by two given self-homeomorphisms A and B. The lemma shows that the definition of "being generated" by a subset used on page 1074 agrees with the above more formal definition.

Proof. We only prove the second statement. The proof of the first statement is very similar. So let G be a group and let $A \subset G$ be a subset. The subgroup $\langle\langle A\rangle\rangle$ contains all elements of A and their inverses. The normal subgroup $\langle\langle A\rangle\rangle$ then contains also all elements of the form $ga^{\pm 1}g^{-1}, g \in G, a \in A$. Since $\langle\langle A\rangle\rangle$ is a subgroup it is also closed under multiplication, i.e. it contains products of such elements. It follows that $\langle\langle A\rangle\rangle$ contains the right-hand side of (2). Conversely it is straightforward to see that the right-hand side is indeed a normal[580] subgroup of G that contains A, hence it is contained in the left-hand side of (2). ■

Lemma 53.4. Let G be a group and let $A \subset G$ be a subset. Let $\alpha\colon G \to \Gamma$ be a group homomorphism such that $\alpha(a) = e \in \Gamma$ for all $a \in A$. Then there exists a unique group homomorphism $\beta\colon G/\langle\langle A\rangle\rangle \to \Gamma$ such that the following diagram commutes:

$$\begin{array}{ccc} G & \longrightarrow & G/\langle\langle A\rangle\rangle \\ & \searrow^{\alpha} & \downarrow{\scriptstyle \beta} \\ & & \Gamma. \end{array}$$

Proof. Let G be a group and let $A \subset G$ be a subset. Furthermore let $\alpha\colon G \to \Gamma$ be a group homomorphism such that $\alpha(a) = e \in \Gamma$ for all $a \in A$. This means that $A \subset \ker(\alpha)$. Since $\ker(\alpha)$ is a normal subgroup it follows from the definition of $\langle\langle A\rangle\rangle$ that $\langle\langle A\rangle\rangle \subset \ker(\alpha)$. The proposition now follows immediately from Lemma 53.1. ■

The following definition will subsequently play an important role:

Definition. Let X be a set and let R be a subset of the free group $\langle X\rangle$ generated by the set X. We define

$$\langle X \mid R\rangle \;:=\; \langle X\rangle \,/\, \langle\langle R\rangle\rangle.$$

If $X = \{x_1, \ldots, x_k\}$ and $R = \{r_1, \ldots, r_l\}$, then we use the convenient shorthand

$$\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l\rangle \;:=\; \langle \{x_1, \ldots, x_k\} \,|\, \{r_1, \ldots, r_l\}\rangle.$$

Examples.

(1) For any $k \in \mathbb{N}_0$ we have

$$\langle g \mid g^k\rangle \;=\; \langle g\rangle/\langle\langle g^k\rangle\rangle \;\underset{\uparrow}{=}\; \langle g\rangle/\langle g^k\rangle \;\cong \mathbb{Z}_k.$$

since $\langle g\rangle$ is abelian it follows from Lemma 53.2 that $\langle\langle g^k\rangle\rangle = \langle g^k\rangle$

(2) The group $\langle x_1, \ldots, x_k \,|\,\rangle$ with $R = \varnothing$ is just the free group on $x_1, \ldots, x_k$.

Before we continue we formulate an elementary but useful lemma.

Lemma 53.5. Let $\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l\rangle$ be a presentation.

(1) Given any $a, b \in \langle x_1, \ldots, x_k\rangle$, given any $i \in \{1, \ldots, l\}$ and given any $\epsilon \in \{-1, 1\}$ we have

[580] Why is the right-hand side normal?

$$a \cdot r_i^{\epsilon} \cdot b \;=\; a \cdot b \;\in\; \langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle.$$

(2) Let $a, b \in \langle x_1, \ldots, x_k \rangle$ and $c, d \in \langle x_1, \ldots, x_k \rangle$. If $a = b \in \langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle$, then $c \cdot a \cdot d \;=\; c \cdot b \cdot d \;\in\; \langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle$.

Proof. The first statement is just a special case of Remark (1) on page 1191 and the second statement is just a special case of Remark (2) on page 1191. ■

This lemma allows us to prove the following lemma.

Lemma 53.6.

(1) There exists a unique homomorphism

$$\beta\colon \pi = \langle x, y \rangle / \langle\langle [x, y] \rangle\rangle = \langle x, y \mid [x, y] \rangle \;\to\; \mathbb{Z}^2$$

with $\beta(x) = (1, 0)$ and $\beta(y) = (0, 1)$. Furthermore this homomorphism is an isomorphism.

(2) Let $m \in \mathbb{N}$. There exists a unique isomorphism

$$\beta\colon \langle x_1, \ldots, x_m \mid [x_i, x_j] = e \text{ for all } i, j \in \{1, \ldots, m\} \rangle \;\xrightarrow{\cong}\; \mathbb{Z}^m$$

which sends each x_i to the i-th standard basis vector e_i of $\mathbb{Z}^m$.

Proof. By Lemma 51.15 there exists a unique homomorphism $\alpha\colon \langle x, y \rangle \to \mathbb{Z}^2$ which satisfies $\alpha(x) = (1, 0)$ and $\alpha(y) = (0, 1)$. Note that

$$\alpha([x, y]) \;=\; \alpha(xyx^{-1}y^{-1}) \;=\; \alpha(x) + \alpha(y) - \alpha(x) - \alpha(y) \;=\; 0.$$

Thus by Lemma 53.4 there exists a unique group homomorphism

$$\beta\colon \pi = \langle x, y \rangle / \langle\langle [x, y] \rangle\rangle = \langle x, y \mid [x, y] \rangle \;\to\; \mathbb{Z}^2$$

with $\beta(x) = (1, 0)$ and $\beta(y) = (0, 1)$. It is clear that β is an epimorphism. Thus it remains to show that α is a monomorphism. This follows immediately from the following claim.

Claim. Given any $w \in \langle x, y \rangle$ there exist $m, n \in \mathbb{Z}$ with $w = x^m y^n \in \langle x, y \mid [x, y] \rangle$.

Proof. First we note that we have the following equalities in $\langle x, y \mid [x, y] \rangle$

$$\underset{\text{Lemma 53.5 (1)}}{yx \;=\; xyx^{-1}y^{-1} \cdot yx} \;=\; xy \qquad \text{and} \qquad xy^{-1} \;=\; y^{-1} \cdot yx \cdot y^{-1} \;\underset{\text{calculation on the left and Lemma 53.5 (2)}}{=\; y^{-1} \cdot xy \cdot y^{-1}} \;=\; y^{-1}x.$$

In Exercise 53.4 we will show that the equalities $yx^{-1} = x^{-1}y$ and $x^{-1}y^{-1} = y^{-1}x^{-1}$ hold in $\pi = \langle x, y \mid [x, y] \rangle$. This means that in π an arbitrary product of powers of x and y can be reordered to equal a product of the $x^m y^n$. For example in π we have the equality

$$x^3y^2x^{-1}y \;=\; x^3y \cdot yx^{-1} \cdot y \;\underset{\text{since } yx^{-1} = x^{-1}y}{=}\; x^3y \cdot x^{-1}y \cdot y \;=\; x^3 \cdot yx^{-1} \cdot y^2 \;\underset{\text{since } yx^{-1} = x^{-1}y}{=}\; x^3 \cdot x^{-1}y \cdot y^2 \;=\; x^2y^3.$$

■

We consider one more example.

Example. We consider the following three self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s+1, 1-t) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s, t+1) \end{array} \quad \text{and} \quad \begin{array}{rcl} \widetilde{A}\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s+1, -t). \end{array}$$

We already know the first two maps from page 1074. We denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. We are interested in the group G

since $\mathbb{R}^2/G$ is the Klein bottle K and by the Fundamental Group-via-Actions Theorem 48.16 we have $\pi_1(K) \cong G$.

Note that $\widetilde{A} = B^{-1}A$. Let $X = \{x, y\}$ be the set that consists of two elements. By Lemma 51.15 there exists a unique homomorphism $\alpha\colon \langle x, y\rangle \to G$ with $\alpha(x) = \widetilde{A}$ and $\alpha(y) = B$. Now let R be the subset of $\langle X\rangle = \langle x, y\rangle$ that consists of the single element $yxyx^{-1}$. We want to consider $\alpha(yxyx^{-1}) \in G$, which is by definition a map from $\mathbb{R}^2$ to $\mathbb{R}^2$. For any point $(s, t) \in \mathbb{R}^2$ this map is given by

$$\begin{aligned}\alpha(yxyx^{-1})(s,t) &= B\widetilde{A}B\widetilde{A}^{-1}(s,t) &&= B\widetilde{A}B(s-1,-t)\\ &&&= B\widetilde{A}(s-1,-t+1) = B(s,t-1) = (s,t).\end{aligned}$$

This shows that $\alpha(yxyx^{-1})$ is the identity map of $\mathbb{R}^2$, i.e. it is the trivial element in G. It follows from Lemma 53.4 that α descends to a homomorphism

$$\beta\colon \langle x, y\rangle/\langle\langle yxyx^{-1}\rangle\rangle = \langle x, y \mid yxyx^{-1}\rangle \to G.$$

This homomorphism is an epimorphism, since the image of β is the group generated by $\widetilde{A} = B^{-1}A$ and B, but this group is the same as the group generated by A and B, i.e. the image of β is G. Is the homomorphism β also a monomorphism? We will come back to this question later on page 1223.

We continue with the following definitions.

Definition.

(1) A presentation is a set X together with a subset $R \subset \langle X\rangle$. We call the elements of X the generators and we call the elements of R the relators[581] of the presentation.

(2) Let π be a group. A presentation for π is a presentation (X, R) together with an isomorphism
$$\langle X \mid R\rangle \xrightarrow{\cong} \pi.$$
Very often one just says $\langle X \mid R\rangle$ is a presentation for π and the explicit isomorphism is suppressed from the notation.

(3) We say that a group π is finitely generated, if π admits a presentation with finitely many generators.[582]

(4) We say a group π is finitely presented, if π admits a presentation with finitely many generators and finitely many relators.

Now we give some examples of finitely generated and finitely presented groups.

Examples.

(1) Every group admits a presentation. Indeed, let π be a group. Then we set $X := \pi$, i.e. X is the set of elements of π. By Lemma 51.15 there exists a unique homomorphism $\alpha\colon \langle X\rangle \to \pi$ with $\alpha(g) = g$ for all $g \in X = \pi$. We set $R := \ker(\alpha)$. Then

$$\langle X \mid R\rangle = \langle X\rangle/\langle\langle R\rangle\rangle = \langle X\rangle/\langle\langle\ker(\alpha)\rangle\rangle \underset{\uparrow}{=} \langle X\rangle/\ker(\alpha) \xrightarrow[\alpha]{\cong} G.$$
by Lemma 53.2 since $R = \ker(\alpha)$ is a normal subgroup

[581] The relators are often also called relations.

[582] This definition of a finitely generated group is equivalent to the one we gave on page 1159. Why is that?

(2) We had just see in Lemma 53.6 (2) that

$$\mathbb{Z}^n \;\cong\; \langle x_1, \dots, x_n \mid [x_i, x_j] = e \text{ with } i, j \in \{1, \dots, n\}\rangle$$

which shows that $\mathbb{Z}^n$ is a finitely presented group.

(3) In fact every finitely generated abelian group is also finitely presented. Indeed, let A be a finitely generated abelian group. Then

$$\begin{array}{ccc} A & \cong & \bigoplus_{i=1}^{n} \mathbb{Z}_{a_i} \\ \uparrow & & \\ \text{Theorem 51.4} & & \\ \text{for some } a_i \in \mathbb{N}_0 & & \end{array} \quad \begin{array}{c} = \\ \uparrow \\ \text{as in (2)} \end{array} \quad \langle x_1, \dots, x_n \mid [x_i, x_j] = e \text{ for } i, j = 1, \dots, n, x_i^{a_i} = e \text{ for } i = 1, \dots, n\rangle.$$

(4) There exist groups which are finitely generated but not finitely presented. In fact there are countably many isomorphism types of finitely presented groups,[583] whereas there are uncountably many isomorphism types of finitely generated groups.[584] A proof for both statements is given in Chapter 14 of [**Rob1995**].

(5) We saw on page 1159 that the fundamental group of the Klein bottle is finitely generated. But is it also finitely presented?

53.3. Tietze transformations.

Definition. Let π be a group and let

$$\phi\colon \langle x_1, \dots, x_k \,|\, r_1, \dots, r_l\rangle \;\xrightarrow{\cong}\; \pi$$

be a presentation. We obtain new presentations as follows:

(1) For any element s of $\langle\langle r_1, \dots, r_l\rangle\rangle \subset \langle X\rangle$ we obtain the presentation

$$\langle x_1, \dots, x_k \mid r_1, \dots, r_l, s\rangle \;=\; \langle x_1, \dots, x_k \mid r_1, \dots, r_l\rangle \;\xrightarrow{\phi}\; \pi.$$

(2) For any $x \neq x_1, \dots, x_k$ and any two words s, t in $x_1, \dots, x_k$ we obtain the presentation[585]

$$\begin{array}{rcl} \langle x_1, \dots, x_k, x \mid r_1, \dots, r_l, s \cdot x \cdot t\rangle & \to & \langle x_1, \dots, x_k \mid r_1, \dots, r_l\rangle \xrightarrow{\phi} \pi. \\ x_i & \mapsto & x_i \\ x & \mapsto & s^{-1} \cdot t \end{array}$$

The above two methods, and their inverses, of obtaining new presentations out of a given one are called Tietze transformations.[586]

The above Tietze transformations show that from a given finite presentation we can obtain infinitely many new finite presentations. This fact is not that surprising. What is much more interesting is the following theorem which was first proved by Heinrich Tietze [**Tie1908**] in 1908.

Theorem 53.7. (Tietze Theorem) Any two finite presentations for a given group are related by a finite sequence of Tietze transformations.

---

[583] That statement is pretty obvious.

[584] This statement is much less obvious. The idea is that in a free group $\langle x_1, \dots, x_k\rangle$ there are uncountably many infinite sequences of elements $\{r_1, r_2, \dots\}$. The difficulty is to show that there exist uncountably many sequences that give raise to non-isomorphic groups.

[586] The map to the left is an isomorphism, in fact an inverse is given by $x_i \mapsto x_i$.

In the proof of the Tietze Theorem 53.7 we will need the following four pretty elementary preparatory lemmas.

Lemma 53.8. Let $\theta\colon G \to H$ be a group homomorphism and let X be a generating set for G. The subgroup of $G * H$ that is generated by $\{g \cdot \theta(g^{-1}) \,|\, g \in G\}$ equals that the subgroup of $G * H$ that is normally generated by $\{x \cdot \theta(x^{-1}) \,|\, x \in X\}$.

Proof of Lemma 53.8. We set $N := \{x \cdot \theta(x^{-1}) \,|\, x \in X\}$. We only need to show that given any $g \in G$ we have $g \cdot \theta(g^{-1}) \in \langle\langle N \rangle\rangle$. This statement follows easily by induction on the length of g as a word in the generating set X and the observation that for $x, y \in X$ we have the following equality:

$$xy \cdot \theta((xy)^{-1}) \;=\; xy \cdot \theta(y^{-1}) \cdot \theta(x^{-1}) \;=\; x \cdot \underbrace{y \cdot \theta(y)^{-1}}_{\in N} \cdot x^{-1} \cdot \underbrace{x \cdot \theta(x^{-1})}_{\in N}.$$

■

Lemma 53.9. Let G and H be two groups, let $\theta\colon G \to H$ be an isomorphism and let $\alpha\colon G \to \pi$ be an isomorphism. We consider the homomorphism

$$\Psi\colon G * H \;\to\; \pi$$

defined by α on G and by $\alpha \circ \theta^{-1}$ on H. The kernel of the homomorphism Ψ is generated by $\{g \cdot \theta(g^{-1}) \,|\, g \in G\}$.

Proof of Lemma 53.9. We set $M := \{g \cdot \theta(g^{-1}) \,|\, g \in G\}$. We need to show that the kernel of the homomorphism Ψ is generated by M. Let $g_1 \cdot h_1 \cdot \dots \cdot g_k \cdot h_k \in \ker(\Psi) \subset G * H$, where we use self-explanatory notation.

If $k = 1$, then it follows from $e = \Psi(g_1 \cdot h_1) = \alpha(g_1) \cdot \alpha(\theta^{-1}(g_1)) = \alpha(g_1 \cdot \theta^{-1}(g_1))$ and the fact that α and θ are isomorphisms that $g_1 \cdot h_1 = g_1 \cdot \theta({g_1}^{-1})$.

Now suppose that $k > 1$. If $g_1 \neq e$, then we can write

$$g_1 \cdot h_1 \cdot g_2 \cdot h_2 \cdot \dots \cdot g_k \cdot h_k \;=\; \underbrace{g_1 \cdot \theta({g_1}^{-1})}_{\in M} \cdot \underbrace{\theta(g_1) \cdot h_1}_{\in H} \cdot g_2 \cdot h_2 \cdot \dots g_k \cdot h_k.$$

If $g_1 = e$, then we write

$$h_1 \cdot g_2 \cdot h_2 \cdot \dots \cdot g_k \cdot h_k \;=\; \underbrace{(\theta^{-1}(h_1) \cdot \theta(\theta^{-1}(h_1)^{-1}))^{-1}}_{\in M} \cdot \underbrace{\theta^{-1}(h_1) \cdot g_2}_{\in G} \cdot h_2 \cdot \dots g_k \cdot h_k.$$

Iterating this procedure we obtain the desired statement. ■

Lemma 53.10. Let

$$\phi\colon \langle x_1, \dots, x_k \,|\, r_1(x_1, \dots, x_k), \dots, r_l(x_1, \dots, x_k)\rangle \;\to\; \pi$$

be a presentation. For pairwise different $y_1, \dots, y_k$ the presentation

$$\begin{aligned} \langle y_1, \dots, y_k \,|\, r_1(y_1, \dots, y_k), \dots, r_l(y_1, \dots, y_k)\rangle &\;\to\; \pi \\ y_i &\;\mapsto\; \phi(x_i) \end{aligned}$$

can be obtained from the original one by Tietze transformations.

Proof of Lemma 53.10. We consider the Tietze transformations

$$\begin{aligned}
\langle x_1,\dots,x_k \,|\, r_1(x_1,\dots,x_k),\dots\rangle &\overset{(2)}{\rightsquigarrow} \langle x_1,\dots,x_k,y_1 \,|\, r_1(x_1,\dots,x_k),\dots,y_1\cdot x_1^{-1}\rangle\\
&\overset{(1)}{\rightsquigarrow} \langle x_1,\dots,x_k,y_1 \,|\, r_1(x_1,\dots,x_k),\dots,y_1\cdot x_1^{-1},r_1(y_1,\dots,x_k),\dots\rangle\\
&\overset{(1)}{\rightsquigarrow} \langle x_1,\dots,x_k,y_1 \,|\, y_1\cdot x_1^{-1},r_1(y_1,\dots,x_k),\dots\rangle\\
&\overset{(1)}{\rightsquigarrow} \langle x_1,\dots,x_k,y_1 \,|\, x_1\cdot {y_1}^{-1},y_1\cdot x_1^{-1},r_1(y_1,\dots,x_k),\dots\rangle\\
&\overset{(1)}{\rightsquigarrow} \langle x_1,\dots,x_k,y_1 \,|\, x_1\cdot {y_1}^{-1},r_1(y_1,\dots,x_k),\dots\rangle\\
&\overset{(2)}{\rightsquigarrow} \langle x_2,\dots,x_k,y_1 \,|\, r_1(y_1,\dots,x_k),\dots\rangle.
\end{aligned}$$

Iterating this process leads to the desired sequence of Tietze transformations. ∎

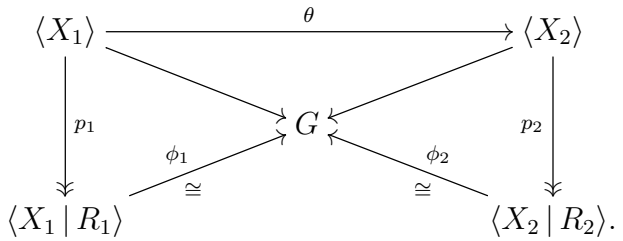
Lemma 53.11. Let $\alpha\colon A\to B$ and $\beta\colon B\to C$ be group epimorphisms. Let $X\subset A$ be a subset such that $\ker(\alpha)=\langle\langle X\rangle\rangle$ and let $Y\subset B$ be a subset such that $\ker(\beta)=\langle\langle\alpha(Y)\rangle\rangle$. Then $\ker(\beta\circ\alpha\colon A\to C)=\langle\langle X\cup Y\rangle\rangle$.

Proof of Lemma 53.11. It is clear that $X\cup Y\subset\ker(\beta\circ\alpha\colon A\to C)$. To prove the reverse inclusion let $g\in\ker(\beta\circ\alpha\colon A\to C)$. We have $\alpha(g)\in\ker(\beta)=\langle\langle\alpha(Y)\rangle\rangle$. Since α is an epimorphism the map $\alpha\colon\langle\langle Y\rangle\rangle\to\langle\langle\alpha(Y)\rangle\rangle$ is an epimorphism. Thus there exists an $h\in\langle\langle Y\rangle\rangle$ with $\alpha(g)=\alpha(h)$. But this implies that $g\cdot h^{-1}\in\ker(\alpha)=\langle\langle X\rangle\rangle$. It follows that $g\in\langle\langle X\cup Y\rangle\rangle$. ∎

Proof of the Tietze Theorem 53.7. Let π be a group and let $\phi_1\colon\langle X_1\,|\,R_1\rangle\xrightarrow{\cong}\pi$ and $\phi_2\colon\langle X_2\,|\,R_2\rangle\xrightarrow{\cong}\pi$ be two finite presentations for π. We need to show that they are related by Tietze transformations. First note that it follows from Lemma 53.10 that by applying a sequence of Tietze transformations we can arrange that $X_1\cap X_2=\varnothing$.

We denote by $p_1\colon\langle X_1\rangle\to\langle X_1\,|\,R_1\rangle$ and $p_2\colon\langle X_2\rangle\to\langle X_2\,|\,R_2\rangle$ the obvious epimorphisms. We set $X:=X_1\sqcup X_2$. We consider the homomorphism

$$\Psi\colon\langle X_1\rangle*\langle X_2\rangle=\langle X\rangle\ \to\ \pi$$



that is induced by $\phi_1\circ p_1$ on $\langle X_1\rangle$ and $\phi_2\circ p_2$ on $\langle X_2\rangle$.

Note that the restriction of Ψ to $\langle X_2\rangle$ is an epimorphism. Therefore we can pick for each $x\in X_1$ a $w_x\in\langle X_2\rangle$ with $\Psi(x)=\Psi(w_x)$. We write $S_1:=\{x\cdot w_x^{-1}\,|\,x\in X_1\}\subset\langle X\rangle$. The same way we define $S_2\subset\langle X\rangle$.

Claim. We have $\ker(\Psi)=\langle\langle R_2\cup S_1\rangle\rangle$.

Proof. First note that it follows almost immediately from Lemmas 53.8, 53.9 and 53.11 that $\ker(\Psi)=\langle\langle R_1\cup R_2\cup S_1\rangle\rangle$. Thus it remains to show that $\langle\langle R_1\cup R_2\cup S_1\rangle\rangle=\langle\langle R_2\cup S_1\rangle\rangle$. Put differently, given $r_1\in R_1$ we need to show that $r_1\in\langle\langle R_2\cup S_1\rangle\rangle$. Let $\theta\colon\langle\langle X_1\rangle\rangle\to\langle\langle X_2\rangle\rangle$ be the homomorphism that is given by $x\mapsto w_x$ for $x\in X_1$. Note that we have the following

commutative diagram:

In particular we have $(\phi_2 \circ p_2)(\theta(r_1)) = (\phi_1 \circ p_1)(r_1) = 1$. This implies that $\theta(r_1) \in \langle\langle R_2 \rangle\rangle$. On the other hand it follows from Lemma 53.8 that $r_1 \cdot \theta(r_1)^{-1} \in \langle\langle S_1 \rangle\rangle$. Thus we see that $r_1 = r_1 \cdot \theta(r_1)^{-1} \cdot \theta(r_1) \in \langle\langle S_1 \cup R_2 \rangle\rangle$. ⊞

After these preparations we turn to the actual proof of the theorem.

(a) First note that we can turn the presentation $\langle X_2 \,|\, R_2 \rangle$ into $\langle X \,|\, R_2 \cup S_1 \rangle$ by a sequence of Tietze transformations (2), where we add one by one the elements of X_1 and for each element of X_1 we add the corresponding relation in S_1.

(b) Note that $R_1 \cup S_2 \subset \ker(\Psi)$. By the claim this implies that $R_1 \cup S_2 \subset \langle\langle R_2 \cup S_1 \rangle\rangle$. In particular, using Tietze transformations (1) we can turn the presentation $\langle X \,|\, R_2 \cup S_1 \rangle$ into the presentation $\langle X \,|\, R_1 \cup S_2 \cup R_2 \cup S_1 \rangle$.

(c) By exactly the same reasoning as in (a) and (b) we can also turn the presentation $\langle X_1 \,|\, R_1 \rangle$ into the presentation $\langle X \,|\, R_1 \cup S_2 \cup R_2 \cup S_1 \rangle$ via a sequence of Tietze transformations.

Since $\langle X_1 \,|\, R_1 \rangle$ and $\langle X_2 \,|\, R_2 \rangle$ can be turned into precisely the same presentation using Tietze transformations, the two presentations are in fact related by Tietze transformations. ■

Remark. Alternative proofs of the Tietze Theorem 53.7 can be found in [**Tie1908**] and also [**LyS1977**, Proposition II.2.2] and [**MKS1976**, Theorem 1.5].

The following lemma often works well in practice to show that two presentations correspond to isomorphic groups.

Lemma 53.12. Let $X = \{x_1, \ldots, x_k\}$ be a finite set and furthermore let $r = \{r_1, \ldots, r_l\}$ be a finite subset of $\langle X \rangle = \langle x_1, \ldots, x_k \rangle$. Suppose that we can write each $r_i(x_1, \ldots, x_k)$ as a word $s_i(x_1, \ldots, x_{k-1}, x_k \cdot w)$ where w is a word in $x_1, \ldots, x_{k-1}$, then the homomorphism

$$\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle \;\to\; \langle x_1, \ldots, x_{k-1}, t \,|\, s_1, \ldots, s_l \rangle$$

that is induced by $x_i \mapsto x_i$, $i = 1, \ldots, k-1$, and $x_k \mapsto t w^{-1}$ is an isomorphism.

Definition. We refer to the isomorphism of Lemma 53.12 as the isomorphism given by the substitution $t = x_k \cdot w$.

Example. A picky reader might decide that the formulation of Lemma 53.12 is not completely precise. But the following example should make the meaning clear:

$$\langle a, b \,|\, a^{-1}ba^{-1}bab^{-1} \rangle \;=\; \langle a, b \,|\, \underbrace{a^{-1}b \cdot a^{-1}b \cdot a \cdot (a^{-1}b)^{-1} \cdot a^{-1}}_{=a^{-1}ba^{-1}bab^{-1}} \rangle \;\underset{\text{substitution } c = a^{-1}b}{\overset{\uparrow}{=}}\; \langle a, c \,|\, c \cdot c \cdot a \cdot c^{-1} \cdot a^{-1} \rangle.$$

Proof. It follows from Lemma 53.13 that there exists in fact a unique homomorphism

$$\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle \;\to\; \langle x_1, \ldots, x_{k-1}, t \,|\, s_1, \ldots, s_l \rangle$$

that has the property that $x_i \mapsto x_i$, $i = 1, \dots, k-1$ and that $x_k \mapsto tw^{-1}$. Furthermore, we have a map from the right to left by the reverse substitution $t \mapsto x_k \cdot w$. It is straightforward to verify that these homomorphisms are inverses of one another, hence both are isomorphisms. ■

As we will now see, finite presentations of groups are useful for finding group homomorphisms. To formulate the corresponding lemma we need the following definition.

Definition. Let $X = \{x_1, \dots, x_k\}$ be a set and let $r \in \langle X \rangle$. Furthermore let G be a group and let $g_1, \dots, g_k$ be elements of G. We say that $g_1, \dots, g_k$ satisfy the relation r if the homomorphism[587] $\langle x_1, \dots, x_k \rangle \to G$ that is given by $x_i \mapsto g_i$, $i = 1, \dots, k$ sends r to the trivial element.

Examples.

(1) We consider $\{x_1, x_2\}$ and the word $r = x_1 x_2 x_1^{-1} x_2^{-1}$. If a group is abelian, then any two elements g_1, g_2 satisfy the relation $x_1 x_2 x_1^{-1} x_2^{-1}$.
(2) Let G be a finite group with d elements. We consider the set $\{x\}$. It follows from Lagrange's Theorem, see e.g. [**KuS2004**, p. 8], that every element in G satisfies the relation x^d.

Lemma 53.13. Let π be a group with a finite presentation $\pi = \langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle$. For any group G the map

$$\begin{array}{rcl} \mathrm{Hom}(\pi, G) & \to & \{\text{all } (g_1, \dots, g_k) \in G^k \text{ that satisfy } r_1, \dots, r_l\} \\ f & \mapsto & (f(x_1), \dots, f(x_k)) \end{array}$$

is a bijection.

Remark. Note that if G is a finite group, then the right-hand side of Lemma 53.13 is a finite set. In practice it is usually straightforward, albeit tedious, to determine the right-hand side.

Proof. This lemma follows immediately from Lemma 53.4 and Lemma 51.15. ■

Next, recall that in Exercise 51.17 we gave an explicit example of a group epimorphism $\varphi\colon \langle x, y \rangle \to \mathbb{Z}$ such that the kernel $\ker(\varphi)$ is infinitely generated. The next proposition shows that this was not a fluke.

Proposition 53.14. Every non-trivial normal subgroup of a free group is infinitely generated.

Proof. A purely group theoretic proof is given in [**LyS1977**, Proposition I.3.12]. Alternatively a proof using topological methods is provided in [**dlH2000**, p. 45]. ■

Fortunately the following proposition, which we obtain from [**DrK2018**, Lemma 7.29], gives us at least some control over the "size" of a kernel.

Proposition 53.15. Let $\varphi\colon \pi \to G$ be a group epimorphism. If π is finitely generated and if G is finitely presented, then $\ker(\varphi)$ is finitely normally generated. In other words, there exists a finite subset $S \subset \ker(\varphi)$ such that $\langle\langle S \rangle\rangle = \ker(\varphi)$.

[587] The fact that there exists a unique such homomorphism is a consequence of Lemma 51.15.

Example. Let $\varphi\colon \langle x, y\rangle \to \mathbb{Z}^2$ be the epimorphism that is given by $\varphi(x) = (1, 0)$ and $\varphi(y) = (0, 1)$. In Exercise 53.10 we will see that $\ker(\varphi)$ is normally generated by a single element, namely the commutator $xyx^{-1}y^{-1}$.

We conclude this section with an interesting little lemma. For the formulation we need the following harmless definition.

Definition. Let G and H be groups. We say H is a retract of G if there exist a group homomorphisms $\varphi\colon H \to G$ and $\rho\colon G \to H$ such that $\rho \circ \varphi = \mathrm{id}_H$.

Lemma 53.16. (Finite Presentation-Retract Lemma) Every retract of a finitely presented group is also finitely presented.

Proof. Let H be a group, let G be a finitely presented group and let $\varphi\colon H \to G$ and $\rho\colon G \to H$ be group homomorphisms such that $\rho \circ \varphi = \mathrm{id}_H$. We need to show that H is also finitely presented.

To do so we pick a finite presentation $G = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l\rangle$ for the group G. We write $F = \langle g_1, \dots, g_k\rangle$. In the following we denote by $p\colon F \to G$ the obvious epimorphism. For each $i \in \{1, \dots, k\}$ we pick $w_i \in F$ with $p(w_i) = (\varphi \circ \rho \circ p)(g_i) \in G$. It suffices to prove the following claim.

Claim. A finite presentation for H is given by $\langle g_1, \dots, g_k \,|\, r_1, \dots, r_l, g_1^{-1}w_1, \dots, g_k^{-1}w_k\rangle$.

Proof. Let L be the group that is defined by the finite presentation of the claim. We denote by $u\colon G \to L$ and $q\colon F \to L$ the obvious projections. Note that for each $j \in \{1, \dots, l\}$ we have $\rho(p(r_i)) = \rho(e) = e$ and for each $i \in \{1, \dots, k\}$ we have

$$\rho(p(g_i^{-1}w_i)) \;=\; \rho(p(g_i^{-1})) \cdot \rho(p(w_i)) \;\underset{\substack{\uparrow\\ \text{since } p(w_i) = (\varphi\circ\rho\circ p)(g_i) \text{ and since } \rho\circ\varphi = \mathrm{id}_H}}{=}\; \rho(p(g_i^{-1})) \cdot \rho(p(g_i)) \;=\; e.$$

It follows from Lemma 53.4 that the homomorphism $p \circ \varphi\colon F \to H$ factors through a homomorphism $v\colon L \to H$.

We want to show that $u \circ \varphi$ is an isomorphism. First note that

$$v \circ (u \circ \varphi) \;=\; (v \circ u) \circ \varphi \;\underset{\substack{\uparrow\\ \text{since } \rho = v\circ u}}{=}\; \rho \circ \varphi \;=\; \mathrm{id}_H\,.$$

By Lemma 51.19 it remains to show that $u\circ\varphi$ is an epimorphism. Note that for $i = 1, \dots, k$ we have

$$(u \circ \varphi)(\underbrace{(\rho \circ p)(w_i)}_{\in H}) \;\underset{\substack{\uparrow\\ \text{since } \varphi\circ\rho = \mathrm{id}_H}}{=}\; u(p(w_i)) \;=\; q(w_i) \;\underset{\substack{\uparrow\\ \text{since } q(w_i) = g_i \in L}}{=}\; g_i \;\in\; L.$$

Since $g_1, \dots, g_k$ is a generating set for L we see that $u \circ \varphi$ is indeed an epimorphism.

For convenience we summarize all objects in the following diagram

$$\begin{array}{ccccc} & \overset{\rho}{\curvearrowleft} & & & \\ H & \underset{v}{\overset{\varphi}{\rightleftarrows}} & G = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l\rangle & \xleftarrow{\;p\;} & F = \langle g_1, \dots, g_k\rangle \\ & & \downarrow u & \swarrow q & \\ & & L := \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l, g_1^{-1}w_1, \dots, g_k^{-1}w_k\rangle. & & \end{array}$$

■

53.4. **The Andrews-Curtis Conjecture.** In this section we want to introduce Nielsen transformations and we want to present the Andrews-Curtis Conjecture. Both are mostly peripheral to the content of these notes. But for general culture it is perhaps interesting to know that in this supposedly fairly elementary context of finite presentations there are difficult conjectures lurking in the background.
First we introduce the following notation.

Notation. Given a set S and $n \in \mathbb{N}_0$ we refer to an element $(g_1, \dots, g_n) \in S^n$ as an ordered set of elements in S.[588]

Now we can introduce the definition we are really interested in.

Definition. Let π be a group and let $(g_1, \dots, g_n)$ be an ordered set of elements in π. A Nielsen operation is one of the following three ways of obtaining a new ordered set of elements in π:

$$\begin{array}{lrcl} (1) & (g_1, g_2, g_3, \dots, g_n) & \rightsquigarrow & (g_1^{-1}, g_2, g_3, \dots, g_n) \\ (2) & (g_1, g_2, g_3, \dots, g_n) & \rightsquigarrow & (g_2, g_1, g_3, \dots, g_n) \\ (3) & (g_1, g_2, g_3, \dots, g_n) & \rightsquigarrow & (g_1 \cdot g_2, g_2, g_3, \dots, g_n). \end{array}$$

The following theorem that was proved by Jakob Nielsen [**Nie1924**] (see also [**LyS1977**, Proposition I.4.1] and [**MKS1976**, Theorem 3.2]) in 1924.

Theorem 53.17. (Nielsen 1924) Let $F = \langle x_1, \dots, x_n \rangle$ be a free group. If $y_1, \dots, y_n \in F$ form a basis[589] for the free group F, then $(y_1, \dots, y_n)$ can be obtained from $(x_1, \dots, x_n)$ through a finite sequence of Nielsen operations (1), (2) and (3).

Remark.

(1) Let $F = \langle g_1, \dots, g_n \rangle$ be a finitely generated free group. It follows from Lemma 51.15 that any Nielsen operation, applied to $(g_1, \dots, g_n)$, gives rise to an endomorphism of the free group F. One can easily show that these endomorphisms are in fact automorphisms of the free group. We refer to any such automorphism as a *Nielsen automorphism*. Nielsen's Theorem 53.17 implies almost immediately that any automorphism of the free group is in fact a composition of finitely many Nielsen automorphisms. In other words, the group $\mathrm{Aut}(F)$ is generated by the Nielsen transformations.
(2) The fact that the group $\mathrm{Aut}(F)$ is generated by the Nielsen operations is similar in spirit to the fact, established in any self-respecting linear algebra course, that the group $\mathrm{Aut}(\mathbb{Z}^n) = \mathrm{GL}(n, \mathbb{Z})$ is generated by elementary matrices.

The following conjecture was formulated by James Andrews and Morton Curtis [**AC1965**] in 1965.

Conjecture 53.18. (Andrews-Curtis Conjecture) Let $\langle g_1, \dots, g_n \,|\, r_1, \dots, r_n \rangle$ be a finite presentation. If the corresponding group is the trivial group, then $(r_1, \dots, r_n)$ can be obtained from $(g_1, \dots, g_n)$ through a finite sequence of operations where we allow the Nielsen operations (1), (2), (3) and the following fourth operation:

$$(4) \qquad (g_1, g_2, g_3, \dots, g_n) \rightsquigarrow (hg_1h^{-1}, g_2, g_3, \dots, g_n) \quad \text{for some } h \in \pi.$$

[588] Note that we do not assume that $g_1, \dots, g_n$ are pairwise different.
[589] Recall that by the definition on page 1159 the elements $y_1, \dots, y_n$ form a basis if the natural map $\langle y_1, \dots, y_n \rangle \to F$ is an isomorphism.

The Andrews-Curtis Conjecture is notoriously difficult. It seems like most experts believe the conjecture to be false, but not much progress has been made over the last decades. Finally note that the Andrews-Curtis Conjecture will raise its head once more in Section 141.2.

53.5. **The abelianization of a group.** The following definition should already be familiar from the algebra course.

Definition. Let π be a group. We refer to

$$[\pi,\pi] \;:=\; \langle\langle \{ \underbrace{[x,y]}_{=xyx^{-1}y^{-1}} \mid x,y\in\pi\}\rangle\rangle$$

as the commutator subgroup of π.

We start out with the following elementary lemma.

Lemma 53.19. Let π be a group. Then the following hold:

(1) The group $\pi/[\pi,\pi]$ is abelian.

(2) We have

$$[\pi,\pi] \;:=\; \left\{ \prod_{i=1}^{n} [x_i,y_i] \,\middle|\, x_1,y_1,\ldots,x_n,y_n\in\pi \right\}.$$

Remark. Note that in general not every element of the commutator subgroup is a commutator. For example, if $\pi=\langle a,b,c,d\rangle$ is the free group on four generators a,b,c,d, then we have $[a,b]\cdot[c,d]\in[\pi,\pi]$, but it is not a commutator.[590]

Proof. Let π be a group.

(1) For any two elements $x,y\in\pi$ we have

$$xy\,[\pi,\pi] \;=\; yx\cdot x^{-1}y^{-1}xy\,[\pi,\pi] \;=\; yx\cdot \underbrace{[x^{-1},y^{-1}]}_{\in[\pi,\pi]}\,[\pi,\pi] \;=\; yx\,[\pi,\pi].$$

This shows that $\pi/[\pi,\pi]$ is indeed abelian.

(2) Note that the inverse of a commutator is again a commutator, i.e. given $x,y\in\pi$ we have

$$[x,y]^{-1} \;=\; (xyx^{-1}y^{-1})^{-1} \;=\; yxy^{-1}x^{-1} \;=\; [y,x].$$

Furthermore a conjugate of a commutator is again a commutator. Indeed, given $x,y,g\in\pi$ we have

$$\begin{aligned} g[x,y]g^{-1} = gxyx^{-1}y^{-1}g^{-1} &= gxg^{-1}gyg^{-1}gx^{-1}g^{-1}gy^{-1}g^{-1} \\ &= (gxg^{-1})(gyg^{-1})(gxg^{-1})^{-1}(gyg^{-1})^{-1} = [gxg^{-1},gyg^{-1}]. \end{aligned}$$

It follows from this discussion and from Lemma 53.3 that each element of the commutator subgroup can be written as a product of commutators, i.e.

$$[\pi,\pi] \;:=\; \left\{ \prod_{i=1}^{n} [x_i,y_i] \,\middle|\, x_1,y_1,\ldots,x_n,y_n\in\pi \right\}.$$

■

Definition. Let π be a group. We call

$$\pi_{\mathrm{ab}} \;:=\; \pi/[\pi,\pi]$$

[590] Why not?

the abelianization of π.[591]

The following proposition summarizes some of the key properties of the abelianization of groups.

Proposition 53.20. (Abelianization Proposition)

(1) If π is abelian, then $\pi_{\text{ab}} = \pi$.

(2) Let π be a group and let $\alpha\colon \pi \to H$ be a homomorphism to an abelian group. Then there exists a unique homomorphism $\beta\colon \pi_{\text{ab}} = \pi/[\pi,\pi] \to H$ such that the following diagram commutes:

$$\begin{array}{ccc} \pi & \longrightarrow & \pi_{\text{ab}} = \pi/[\pi,\pi] \\ & \searrow^{\alpha} & \downarrow{\scriptstyle \beta} \\ & & H. \end{array}$$

In particular for any group π and any abelian group G the map

$$\begin{array}{rcl} \text{Hom}(\pi_{\text{ab}}, G) & \to & \text{Hom}(\pi, G) \\ (\alpha\colon \pi_{\text{ab}} \to G) & \mapsto & \big(\pi \to \pi_{\text{ab}} \xrightarrow{\alpha} G\big) \end{array}$$

is a bijection.

(3) Let G and H be two groups. There exists a unique isomorphism

$$(G * H)_{\text{ab}} \xrightarrow{\cong} G_{\text{ab}} \times H_{\text{ab}}$$

which makes the following diagram commute:

$$\begin{array}{ccc} G * H & \twoheadrightarrow & G \times H \\ \downarrow\!\downarrow & & \downarrow\!\downarrow \\ (G * H)_{\text{ab}} & \xrightarrow{\cong} & G_{\text{ab}} \times H_{\text{ab}}, \end{array}$$

where the other three maps are the natural projections.

(4) Let $F = \langle x_1, \ldots, x_m\rangle$ be the free group on m generators $x_1, \ldots, x_m$. Then the map[592]

$$\begin{array}{rcl} \Phi\colon F_{\text{ab}} = F/[F,F] & \to & \mathbb{Z}^m \\ [x_i] & \mapsto & e_i := \text{the } i\text{-th standard basis vector} \end{array}$$

is an isomorphism.

(5) Let $\pi = \langle x_1, \ldots, x_m \mid r_1, \ldots, r_n\rangle$ be a finitely presented group. We denote by

$$\Phi\colon \langle x_1, \ldots, x_m\rangle \to \mathbb{Z}^m$$

the homomorphism that is given by $\Phi(x_i) = e_i$. There exists a unique isomorphism

$$\Psi\colon \pi/[\pi,\pi] \xrightarrow{\cong} \mathbb{Z}^m/\langle \Phi(r_1), \ldots, \Phi(r_n)\rangle$$

[591] The abelianization of a group π is sometimes also written as $\text{H}_1(\pi)$. The reason for that somewhat strange looking notation will become clear later on when we formulate the Hurewicz Theorem 84.5 and when we consider the homology groups, see Chapter **??**.

such that the following diagram commutes

$$\begin{array}{ccc} \langle x_1,\dots,x_m\rangle & \xrightarrow[\Phi]{x_i\mapsto e_i} & \twoheadrightarrow \mathbb{Z}^m \\ \downarrow & & \\ \pi = \langle x_1,\dots,x_m\rangle/\langle\langle r_1,\dots,r_n\rangle\rangle & & \downarrow \\ \downarrow & & \\ \pi_{\mathrm{ab}} = \pi/[\pi,\pi] & \xrightarrow[\cong]{\Psi} & \mathbb{Z}^m/\langle\Phi(r_1),\dots,\Phi(r_n)\rangle. \end{array}$$

(6) The maps

$$G \;\mapsto\; G_{\mathrm{ab}} = G/[G,G]$$

and

$$(\varphi\colon G\to H) \;\mapsto\; \left(\begin{array}{rcl} \varphi_*\colon G_{\mathrm{ab}} = G/[G,G] & \to & H_{\mathrm{ab}} = H/[H,H] \\ [g] & \mapsto & [\varphi(g)] \end{array}\right)$$

define a covariant functor from the category *Group* of groups to the category *AbGroup* of abelian groups.

(7) Given a group G we denote by

$$\begin{array}{rcl} \Phi_G\colon G & \to & G_{\mathrm{ab}} = G/[G,G] \\ g & \mapsto & [g] \end{array}$$

the projection . These maps Φ_G define a natural transformation from the identity functor *Group* $\to$ *Group* to the abelianization functor *Group* $\to$ *Group* that we had introduced in (6).[593]

(8) Isomorphic groups have isomorphic abelianizations.

(9) If $\varphi\colon A\to B$ is an epimorphism, then the induced map $A_{\mathrm{ab}}\to B_{\mathrm{ab}}$ is also an epimorphism.

Examples.

(1) By the Abelianization Proposition 53.20 (1) and (3) we have

$$(\mathbb{Z}_3 * \mathbb{Z}_{35})_{\mathrm{ab}} \;\cong\; \mathbb{Z}_3\times\mathbb{Z}_{35} \quad\text{and}\quad (\mathbb{Z}_5 * \mathbb{Z}_{21})_{\mathrm{ab}} \;\cong\; \mathbb{Z}_5\times\mathbb{Z}_{21}.$$

It follows from the Chinese Remainder Theorem that the abelianizations are isomorphic. On the other hand on page 1164 we had already observed that the Grushko Decomposition Theorem 51.22 implies that the groups $\mathbb{Z}_3 * \mathbb{Z}_{35}$ and $\mathbb{Z}_5 * \mathbb{Z}_{21}$ are not isomorphic. Thus we have seen that non-isomorphic groups can have isomorphic abelianizations.

(2) We give an explicit example for Statement (5). Let

$$\pi \;=\; \langle x, y \mid x^2y^{-2}x, y^{-1}x^3yx\rangle.$$

[592]By Lemma 51.15 there exists a unique homomorphism $F\to\mathbb{Z}^m$ with $x_i\mapsto e_i$. By (1) this map descends to a homomorphism $F/[F,F]\to\mathbb{Z}^m$. The way we write down the map is a little bit sloppy, since we only specify the map on the generators of $F/[F,F]$.

[593]Super-picky readers might argue that in (6) we introduced a functor from *Group* to *AbGroup*, but of course we can also view it as a functor from $\mathcal{G}$ to $\mathcal{G}$.

Let $\Phi\colon \langle x, y\rangle \to \mathbb{Z}^2$ be the epimorphism given by $\Phi(x) = (1, 0)$ and $\Phi(y) = (0, 1)$. Then the abelianization of π is given by[594]

$$\pi_{\text{ab}} \;=\; \mathbb{Z}^2/\langle \underbrace{\Phi(x^3y^{-2})}_{=\binom{3}{-2}}, \underbrace{\Phi(y^{-1}x^3yx)}_{=\binom{4}{0}} \rangle \;=\; \mathbb{Z}^2/\begin{pmatrix} 3 & 4 \\ -2 & 0 \end{pmatrix}\mathbb{Z}^2 \;\cong\; \mathbb{Z}_8.$$

(3) Let S be a set. It is straightforward to show that the abelianization of the free group $\langle S\rangle$ generated by S is isomorphic to the free abelian group $\mathbb{Z}^{(S)}$ generated by S.
(4) Given $k \in \mathbb{N}$ we denote by S_k the permutation group on k elements and we denote by $A_k \subset S_k$ the alternating group, i.e. the group of all permutations with positive sign. In the algebra course it was shown that for $k \geq 5$ the group A_k is simple, i.e. the only normal subgroups of A_k are the trivial group and the group A_k itself.[595] The commutator subgroup $[A_k, A_k]$ is normal. Since A_k is not abelian we cannot have $[A_k, A_k] = \{e\}$. Thus we see that $[A_k, A_k] = A_k$, which implies that the abelianization of A_k is the trivial group.

Now we provide the proof of the Abelianization Proposition 53.20.

Proof of the Abelianization Proposition 53.20.

(1) The first statement is obvious.[596]
(2) Let π be a group and let $\alpha\colon \pi \to H$ be a homomorphism to an abelian group. Then $[\pi, \pi]$ lies in the kernel of α. The desired statement now follows immediately from Lemma 53.1.
(3) The maps

$$\begin{array}{rcl} \Phi\colon (G * H)_{\text{ab}} & \to & G_{\text{ab}} \times H_{\text{ab}} \\ [(x_1, \ldots, x_k)] & \mapsto & \left(\left[\prod_{x_i \in G} x_i\right], \left[\prod_{x_i \in H} x_i\right]\right) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon G_{\text{ab}} \times H_{\text{ab}} & \to & (G * H)_{\text{ab}} \\ ([g], [h]) & \mapsto & [g \cdot h] \end{array}$$

are easily seen to be well-defined, to be homomorphisms and to be inverses of one another.
(4) This statement follows immediately from the statements (1) and (3) together with the observation that $\langle x_1, \ldots, x_m\rangle = \langle x_1\rangle * \cdots * \langle x_m\rangle$, that $\langle x_i\rangle_{\text{ab}} \cong \mathbb{Z}$ and that $\mathbb{Z}^m = \mathbb{Z} \times \cdots \times \mathbb{Z}$.
(5) It is straightforward to see that there exists a unique homomorphism

$$\Psi\colon \pi/[\pi, \pi] \;\to\; \mathbb{Z}^m/\langle \Phi(r_1), \ldots, \Phi(r_n)\rangle$$

that makes the diagram of Statement (5) commute. It remains to show that Ψ is an isomorphism. We write $F = \langle x_1, \ldots, x_m\rangle$ and we write $G = \langle y_1, \ldots, y_n\rangle$. We

[594] Why is the group isomorphic to $\mathbb{Z}_8$?
[595] A proof of this statement is also given in any self-respecting algebra book, see e.g. [**Rob1995**, p. 69].
[596] Why?

consider the following diagram

$$\begin{array}{ccc} G_{\mathrm{ab}} = G/[G,G] & \xrightarrow[\cong]{[y_i]\mapsto e_i} & \mathbb{Z}^n \\ \downarrow{\scriptstyle [y_i]\mapsto [r_i]} & & \downarrow{\scriptstyle e_i\mapsto \Phi(r_i)} \\ F_{\mathrm{ab}} = F/[F,F] & \xrightarrow[\cong]{\Phi([x_i])=e_i} & \mathbb{Z}^m \\ \downarrow & & \downarrow \\ \pi_{\mathrm{ab}} = \pi/[\pi,\pi] & \xrightarrow{\Psi} & \dfrac{\mathbb{Z}^m}{\langle \Phi(r_1),\dots,\Phi(r_n)\rangle}. \end{array}$$

Note that the diagram commutes. By (4) the top two horizontal maps are isomorphisms. The bottom vertical maps are clearly epimorphisms and it is clear that the images of the top vertical maps lie in the kernel of the bottom vertical maps. It now follows from an elementary "diagram chase" that the bottom horizontal map is also an isomorphism.[597] We leave the details to the reader.

(6) This statement follows easily from the definitions and the observation that the image of a commutator under a group homomorphism is once again a commutator.
(7) This statement is basically obvious once one has internalized the definition of a natural transformation.
(8) This statement is an immediate consequence of (6).
(9) We will prove this statement in Exercise 53.6. ■

53.6. **The amalgamated product of groups I.** In the formulation of the generalized version of the Seifert–van Kampen theorem we will need to replace the free product of two groups by the "amalgamated product" of two groups.

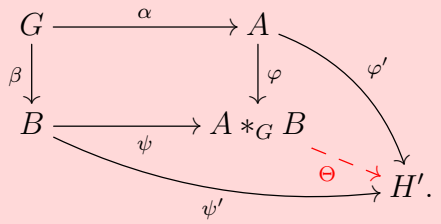
In Section 51.2 we had first defined the free product via an explicit construction. We had then explained that one can also characterize the free product via a universal property. In this section we will proceed the other way round, we will first state the desired universal property and then we will explicitly construct a group which satisfies the universal property.

Proposition 53.21. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. Then there exists a triple

$$(A *_G B, \varphi\colon A \to A *_G B, \psi\colon B \to A *_G B)$$

[597] More precisely, we use the following fact: suppose we are given a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{\cong} & A' \\ \downarrow & & \downarrow \\ B & \xrightarrow{\cong} & B' \\ \downarrow & & \downarrow \\ C & \longrightarrow & C', \end{array}$$



of group homomorphisms where the bottom vertical maps are epimorphisms, where the top two horizontal maps are isomorphisms and where the kernels of the bottom vertical maps are the images of the top vertical maps. Then the bottom horizontal map is also an isomorphism. This general statement can be proved by a "diagram chase". This statement can also be viewed as a special case of the "five lemma".

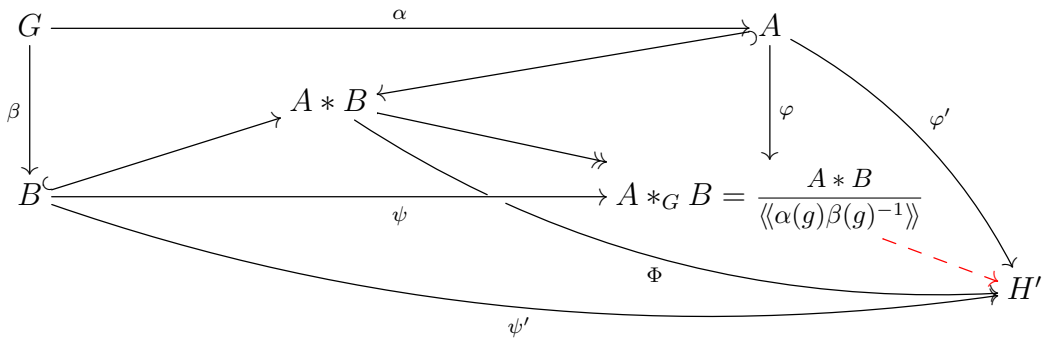
where $A *_G B$ is a group and φ and ψ are homomorphisms with the following properties:

(a) the following diagram commutes:

$$\begin{array}{ccc} G & \xrightarrow{\alpha} & A \\ {\scriptstyle\beta}\downarrow & & \downarrow{\scriptstyle\varphi} \\ B & \xrightarrow[\psi]{} & A *_G B, \end{array}$$

(b) if $(H', \varphi' \colon A \to H', \psi' \colon B \to H')$ is another triple which satisfies property (a), then there exists a unique homomorphism $\Theta \colon A *_G B \to H'$ such that $\varphi' = \Theta \circ \varphi$ and $\psi' = \Theta \circ \psi$, i.e. such that the following diagram commutes

Proof. Let $\alpha \colon G \to A$ and $\beta \colon G \to B$ be two group homomorphisms. As usual we view A and B as subgroups of $A * B$. We put



$$A *_G B \;:=\; A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle$$

and we define $\varphi \colon A \to A *_G B$ as the composition of the obvious homomorphisms

$$A \;\hookrightarrow\; A * B \;\twoheadrightarrow\; A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle,$$

and precisely the same way we define the homomorphism $\psi \colon B \to A *_G B$. It follows from the construction of $A *_G B$ that $\varphi(\alpha(g)) = \psi(\beta(g))$ for all $g \in G$. Therefore the triple $(A *_G B, \varphi \colon A \to A *_G B, \psi \colon B \to A *_G B)$ satisfies property (a).

Now let $(H', \varphi' \colon A \to H', \psi' \colon B \to H')$ be another triple which satisfies property (a). We consider the following diagram

where $\Phi \colon A * B \to H'$ is the unique homomorphism determined by ψ' and φ'. Since $\varphi' \circ \alpha = \psi' \circ \beta$ it follows that for any $g \in G$ we have

$$\Phi(\alpha(g) \cdot \beta(g)^{-1}) \;=\; \Phi(\alpha(g)) \cdot \Phi(\beta(g))^{-1} \;=\; \varphi'(\alpha(g)) \cdot \psi'(\beta(g))^{-1} \;=\; e.$$

Put differently, all elements of the form $\alpha(g)\beta(g)^{-1}$ in $A * B$ lie in the kernel of Φ. By Lemma 53.4 there exists a unique homomorphism $\Theta \colon A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle \to H'$

which makes the following diagram commute

$$\begin{array}{ccc} A * B & \longrightarrow & A *_G B = A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g\in G} \rangle\rangle \\ & \searrow^{\Phi} & \downarrow \Theta \\ & & H'. \end{array}$$

This proves the existence of Θ. The uniqueness follows from the observation that another choice of Θ' would give another choice for Φ, but this homomorphism is unique. ■

Definition. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. We write

$$A *_G B \;:=\; A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g\in G} \rangle\rangle$$

and we refer to $A *_G B$ as the amalgamated product of A and B with amalgam G.[598] We refer to the obvious homomorphisms $A \to A *_G B$ and $B \to A *_G B$ as the natural homomorphisms.[599]

Remark. A variation on the argument on page 1149 shows that if

$$(H, \varphi\colon A \to H, \psi\colon B \to H)$$

is a triple that has both the properties (a) and (b) of Proposition 53.21, then there exists a unique isomorphism $\Theta\colon A *_G B \xrightarrow{\cong} H$ such that $\varphi(a) = \Theta(a)$ for all $a \in A$ and $\psi(b) = \Theta(b)$ for all $b \in B$. Often we will use this uniquely defined isomorphism to identify H with the amalgamated product $A *_G B$.

Example. Let $G = \mathbb{Z}_2, A = \mathbb{Z}_4$ and $B = \mathbb{Z}_6$ and consider the homomorphisms

$$\begin{array}{rcl} \alpha\colon G & \to & A \\ [k] & \mapsto & [2k] \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta\colon G & \to & B \\ [k] & \mapsto & [3k]. \end{array}$$

Furthermore we consider the homomorphisms[600]

$$\begin{array}{rcl} \varphi\colon A = \mathbb{Z}_4 & \to & \mathrm{SL}(2,\mathbb{Z}) \\ k & \mapsto & \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}^k \end{array} \quad \text{and} \quad \begin{array}{rcl} \varphi\colon B = \mathbb{Z}_6 & \to & \mathrm{SL}(2,\mathbb{Z}) \\ k & \mapsto & \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}^k. \end{array}$$

It is straightforward to verify that[601] $\varphi \circ \alpha = \psi \circ \beta$, therefore there exists by Proposition 53.21 a homomorphism

$$A *_G B \;=\; \mathbb{Z}_4 *_{\mathbb{Z}_2} \mathbb{Z}_6 \;\to\; \mathrm{SL}(2,\mathbb{Z}).$$

More surprisingly, this homomorphism is in fact an isomorphism. We refer to [**Rosb1994**, p. 218] and [**Ser1980**, p. 35] for a proof.

The following lemma summarizes some important special cases of the amalgamated product of groups.

---

[598] The notation is a little misleading since the homomorphisms α and β do not get mentioned in the notation, even though they play of course an important role. In particular different choices of α and β can lead to non-isomorphic amalgamated products.

[599] We leave it again to the reader to figure out in what sense these homomorphisms are "natural".

[600] Are these really homomorphisms?

[601] Indeed, the one non-trivial element of $G = \mathbb{Z}_2$ gets sent under both maps to $-\mathrm{id}$.

Lemma 53.22. (Amalgamated Product Lemma)

(1) For two groups A and B and $G = \{e\}$ the trivial group, the corresponding amalgamated product is the usual free product, i.e.

$$A *_{\{e\}} B \ = A * B.$$

(2) If $\alpha\colon G \to A$ is a group homomorphism and if $\beta\colon G \to \{e\}$ is the trivial homomorphism, then

$$A *_G \{e\} \ = \ A/\langle\langle \alpha(G) \rangle\rangle.$$

(3) Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be group homomorphisms. We consider the diagram

$$\begin{array}{ccc} G & \xrightarrow{\quad\alpha\quad} & A \\ {\scriptstyle\beta}\downarrow & & \downarrow \\ B & \longrightarrow & A *_G B. \end{array}$$

The following two statements hold:[602]

(a) If the left vertical map β is an isomorphism, then the right vertical map is also an isomorphism and the inverse $A *_G B \to A$ is given by the identity on A and $\beta^{-1}\colon B \to G$.

(b) If the left vertical map β is an epimorphism, then the right vertical map is also an epimorphism.

(4) Let A, B, C and G, H be groups and let $\alpha\colon G \to A$, $\beta\colon G \to B$, $\widetilde{\beta}\colon H \to B$ and $\gamma\colon H \to C$ be group homomorphisms. Then the universal properties of the amalgamated products define an isomorphism[603]

$$(A *_G B) *_H C \ \xrightarrow{\cong}\ A *_G (B *_H C).$$

(5) Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be group homomorphisms and let $\varphi\colon H \to G$ be an epimorphism. The natural map $A *_G B \to A *_H B$ is an isomorphism.

(6) Let $\alpha\colon G * H \to A$ and $\beta\colon G * H$ to be group homomorphisms. If the restriction of β to H is trivial, then the natural map $A *_{G*H} B \to A/\langle\langle H \rangle\rangle *_G B$ is an isomorphism.

Remark. The Amalgamated Product Lemma 53.22 (4) is actually quite useful since it allows us to form iterated amalgamated products without having to worry about parentheses.

Sketch of proof. The first two statements follow immediately from the definition

$$A *_G B \ := \ A * B/\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g\in G} \rangle\rangle.$$

The remaining statement follow either directly from the universal property of the amalgamated product or from the actual description. For some statements we will fill in the details in Exercise 53.14. ■

The following lemma gives us a convenient description of the amalgamated product of two finitely presented groups.

---

[602] The statements are similar in spirit to the statement of the Topological Pushout-Maps Lemma 5.34 for the pushout of topological spaces.

[603] In an attempt to lessen the burden on the reader we refrained from writing down the super-precise statement.

Lemma 53.23. Let

$$A = \langle x_1, \dots, x_k \mid r_1, \dots, r_p \rangle$$

and

$$B = \langle y_1, \dots, y_l \mid s_1, \dots, s_q \rangle$$

be two finitely presented groups. Furthermore let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms and let $g_1, \dots, g_m$ be generators of G. Then

$$A *_G B = \langle x_1, \dots, x_k, y_1, \dots, y_l \mid r_1, \dots, r_p, s_1, \dots, s_q \text{ and } \alpha(g_i) = \beta(g_i), i = 1, \dots, m \rangle.$$

Examples.

(1) Let $A_1 = \langle x_1, y_1 \rangle$ and $A_2 = \langle x_2, y_2 \rangle$ be two free groups. Furthermore for $i = 1, 2$ let $\varphi_i\colon \langle t \rangle \to A_i$ be the homomorphism that is given by $\varphi_i(t^n) := [x_i, y_i]^n$. Then we obtain from Lemma 53.23 that

$$A_1 *_{\langle t \rangle} A_2 = \langle x_1, y_1, x_2, y_2 \mid [x_1, y_1] = [x_2, y_2] \rangle.$$

(2) Let $A = \langle a \rangle$ and let $B = \langle b \rangle$ be two infinite cyclic groups and let $G = \langle x, y \mid [x, y] \rangle$ be a group that is isomorphic to $\mathbb{Z}^2$. We consider the homomorphism $\alpha\colon G \to A$ that is given by $\alpha(x) = a$ and $\alpha(y) = e$ and we consider the homomorphism $\beta\colon G \to B$ that is given by $\beta(x) = e$ and $\beta(y) = b$. Then

$$A *_G B \underset{\text{Lemma 53.23}}{=} \langle a, b \mid \alpha(x) = \beta(x), \alpha(y) = \beta(y) \rangle = \langle a, b \mid a = e, e = b \rangle \underset{\text{Tietze transformation (2), see page 1196}}{=} \langle | \rangle = \{e\}.$$

This shows in particular that the amalgamated product of two non-trivial groups can in fact be trivial.

Proof of Lemma 53.23. We need to show that

$$\underbrace{\frac{A*B}{\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle}}_{\text{definition of } A*_G B} = \underbrace{\frac{A*B}{\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle}}_{\text{right-hand side of the proposition}}.$$

Put differently, we need to prove the following claim.

Claim. In the free product $A * B$ we have

$$\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle = \langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle.$$

Proof. It is clear that the right-hand side is contained in the left-hand side. To show the reverse inclusion we need to show that for each $g \in G$ we have $\alpha(g)\beta(g)^{-1} \in \langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$. We start out with two observations:

(1) We first consider the case $g = g_i^{-1}$ for some i. Then

$$\alpha(g)\beta(g)^{-1} = \alpha(g_i^{-1})\beta(g_i^{-1})^{-1} = \alpha(g_i)^{-1}\big(\alpha(g_i)\beta(g_i^{-1})\big)^{-1}\alpha(g_i),$$

thus $\alpha(g)\beta(g)^{-1}$ is a conjugate of the inverse of $\alpha(g_i)\beta(g_i^{-1})$, in particular it lies in $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$.

(2) Note that if a, b and c are elements in a group π such that ac and b lie in a normal subgroup Γ, then $abc = ac \cdot c^{-1}bc$ also lies in Γ.

Now we turn to the proof of the claim. We define the *length* of $g \in G$ as

$$\ell(g) = \min\{n \mid \text{ we can write } g = g_{i_1}^{\epsilon_1} \cdot \dots \cdot g_{i_n}^{\epsilon_n} \text{ for } \epsilon_j \in \{-1, 1\} \text{ and } i_j \in \{1, \dots, m\}\}.$$

Since $g_1, \dots, g_m$ are generators of G any $g \in G$ has a length.

We prove the claim by induction on the length of $g \in G$. For $\ell(g) = 0$ there is nothing to prove. Now suppose we have shown the claim for all elements of length $n-1$. Now let $g \in G$ be an element of length n. Thus we can write $g = g_{i_1}^{\epsilon_1} \cdot \cdots \cdot g_{i_n}^{\epsilon_n}$ for $\epsilon_1, \ldots, \epsilon_n \in \{-1, 1\}$ and $i_1, \ldots, i_n \in \{1, \ldots, m\}$. We then have

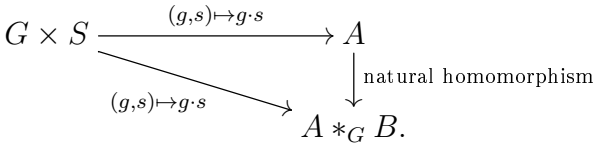
$$\begin{aligned} \alpha(g)\beta(g)^{-1} = \alpha(g)\beta(g^{-1}) &= \alpha\big(g_{i_1}^{\epsilon_1} \cdots g_{i_n}^{\epsilon_n}\big) \cdot \beta\big(g_{i_n}^{-\epsilon_n} \cdots g_{i_1}^{-\epsilon_1}\big) \\ &= \underbrace{\alpha\big(g_{i_1}^{\epsilon_1}\big) \cdots \alpha\big(g_{i_{n-1}}^{\epsilon_{n-1}}\big)}_{=:a} \cdot \underbrace{\alpha\big(g_{i_n}^{\epsilon_n}\big) \cdot \beta\big(g_{i_n}^{-\epsilon_n}\big)}_{=:b} \cdot \underbrace{\beta\big(g_{i_{n-1}}^{-\epsilon_{n-1}}\big) \cdots \beta\big(g_{i_1}^{-\epsilon_1}\big)}_{=:c}. \end{aligned}$$

Note that b lies in the normal subgroup $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\ldots,m} \rangle\rangle$ by (1) and ac lies in the normal subgroup $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\ldots,m} \rangle\rangle$ by induction. Thus $abc = \alpha(g)\beta(g)^{-1}$ lies in $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\ldots,m} \rangle\rangle$ by (2). ■

53.7. **The amalgamated product of groups II.** In this last section we will state and outline proofs of a few more advanced properties of amalgamated products.
Recall that on page 1211 we saw that the amalgamated product of two non-trivial groups can be trivial. The following proposition gives a criterion for the amalgamated product to be non-trivial.

Proposition 53.24. (Amalgamated Product-Monomorphism Proposition) Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. If α and β are both monomorphisms, then the natural homomorphisms $A \to A *_G B$ and $B \to A *_G B$ are also both monomorphisms.

Convention. If we are in the setting of the Amalgamated Product-Monomorphism Proposition 53.24, then we will use the natural monomorphisms $A \to A *_G B$ and $B \to A *_G B$ to identify A, B and G with the images in $A *_G B$ under these monomorphisms.

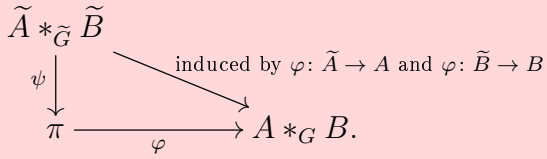


Remark. In Exercise 53.12 we will see that there exists an injective group homomorphism $\alpha\colon G \to A$ and a non-injective group homomorphism $\beta\colon G \to B$ such that the amalgamated product $A *_G B$ is trivial. This shows that there is no obvious way how one can weaken the hypothesis in the Amalgamated Product-Monomorphism Proposition 53.24 that both maps are monomorphisms.

The proof of the Amalgamated Product-Monomorphism Proposition 53.24 relies on the following proposition which is proved in [**Ser1980**, p. 3], or alternatively [**vdW1948**], [**LyS1977**, Theorem IV.2.6] and [**CgRR2008**, Satz 5.2].

Theorem 53.25. (Normal Form Theorem) Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group monomorphisms. We identify G with its image in A and B. Let $S \subset A$ be a set of coset representatives for $G\backslash A$ and let $T \subset B$ be a set of coset representatives for $G\backslash B$. Then any element h in $A *_G B$ we can be written *uniquely* as a product $h = g \cdot c_1 \cdots c_k$ where $g \in G$ and $c_1, \ldots, c_k \in S \sqcup T$.

Proof of the Amalgamated Product-Monomorphism Proposition 53.24. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group monomorphisms. Let S be a set of coset representatives for $G\backslash A$ and let T be a set of coset representatives for $G\backslash B$. We have the following modest



commutative diagram

The top map is a bijection by definition of S. Furthermore the diagonal map is an injection by the Normal Form Theorem 53.25. Thus the vertical map is a monomorphism. ■

We conclude this chapter with another consequence of the Normal Form Theorem 53.25.

Proposition 53.26. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group monomorphisms. Furthermore let $\varphi\colon \pi \to A *_G B$ be a group epimorphism. We write $\widetilde{A} := \varphi^{-1}(A)$, $\widetilde{B} := \varphi^{-1}(B)$ and $\widetilde{G} := \varphi^{-1}(G)$. Then there exists a unique isomorphism $\psi\colon \widetilde{A} *_{\widetilde{G}} \widetilde{B} \to \pi$ which makes the following diagram commute:

Proof. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group monomorphisms. It follows from the universal property of the amalgamated product that there exists a unique homomorphism $\psi\colon \widetilde{A} *_{\widetilde{G}} \widetilde{B} \to \pi$ which makes the above diagram commute. It remains to show that ψ is an isomorphism.

Let S be a set of coset representatives for $G\backslash A$ and let T be a set of coset representatives for $G\backslash B$. By the Normal Form Theorem 53.25 we know that any element h in $A *_G B$ we can be written *uniquely* as a product $h = g \cdot c_1 \cdots c_k$ where $g \in G$ and $c_1, \ldots, c_k \in S \sqcup T$. We write $\ell(h) := k$.

Now we turn to the proof that ψ is an epimorphism. We need to show that every $g \in \pi$ lies in the image of ψ. We prove this statement by induction on $\ell(\varphi(g))$. If $\ell(\varphi(g)) \leq 1$, then $\varphi(g) \in A$ or $\varphi(g) \in B$. But this means that $g \in \psi(\widetilde{A})$ or $g \in \psi(\widetilde{B})$. Suppose we know that we have an $n \in \mathbb{N}$ such that the desired statement holds whenever $\ell(\varphi(g)) \leq n$. Let $g \in \pi$ with $\ell(\varphi(g)) = n + 1$. Since φ is an epimorphism we see that there exist $x, y \in \pi$ with $g = x \cdot y$ such that $\ell(\varphi(x)) = n$ and $\ell(\varphi(y)) = 1$. By induction we know that x and y lie in the image of ψ. But then so does $g = x \cdot y$.

It remains to show that ψ is also a monomorphism. Thus let $h \in \ker(\psi)$. Since φ restricts to a surjective map $\widetilde{G}\backslash\widetilde{A} \to G\backslash A$ we see that there exists a set $\widetilde{S}$ of coset representatives for $\widetilde{G}\backslash\widetilde{A}$ with $\varphi(\widetilde{S}) \subset S$. Similarly there exists a set $\widetilde{T}$ of coset representatives for $\widetilde{G}\backslash\widetilde{B}$ with $\varphi(\widetilde{T}) \subset T$. By the Normal Form Theorem 53.25 we can write $h = \widetilde{g} \cdot \widetilde{c}_1 \cdot \cdots \cdot \widetilde{c}_k$ with $\widetilde{g} \in \widetilde{G}$ and $\widetilde{c}_1, \ldots, \widetilde{c}_k \in \widetilde{S} \sqcup \widetilde{T}$. Note that

$$e \;=\; \varphi(e) \;=\; \varphi(\psi(h)) \underset{\text{since the diagram commutes}}{=} \varphi(\widetilde{g}) \cdot \underbrace{\varphi(\widetilde{c}_1)}_{\in S \sqcup T} \cdot \cdots \cdot \underbrace{\varphi(\widetilde{c}_k)}_{\in S \sqcup T} \;\in\; A *_G B.$$

It follows immediately from the uniqueness statement of the Normal Form Theorem 53.25 that $k = 0$, i.e. we see that $h = \widetilde{g} \in \widetilde{G}$. But the restriction of $\psi\colon \widetilde{A} *_{\widetilde{G}} \widetilde{B} \to \pi$ to $\widetilde{G}$ is of

course just the inclusion $\widetilde{G} \to \pi$, in particular the restriction is a monomorphism. Thus we see that $h = e$. ■

Exercises for Chapter 53.

Exercise 53.1. Let π be a group and let $A, B \subset \pi$ be two subsets of π. Show that there exists a natural isomorphism between $(\pi/\langle\langle A \rangle\rangle)/\langle\langle B \rangle\rangle$ and $\pi/\langle\langle A \cup B \rangle\rangle$.

Exercise 53.2. Let π be a finitely generated group. Show that every finite-index subgroup is also finitely generated.
Remark. In Proposition 69.15 we will prove the more subtle result that every finite-index subgroup of a finitely presented group is finitely presented.

Exercise 53.3. Let π be a finitely generated group and let G be a finite group. Show that the set $\mathrm{Hom}(\pi, G)$ of homomorphisms from π to G is a finite set.

Exercise 53.4.

(a) Show that
$$\langle x_1, \ldots, x_k \,|\, x_k \rangle \;\cong\; \langle x_1, \ldots, x_{k-1} \rangle.$$
(b) Show that in the group $\langle x, y \,|\, xyx^{-1}y^{-1} \rangle$ we have the equalities $yx^{-1} = x^{-1}y$ and $x^{-1}y^{-1} = y^{-1}x^{-1}$.

Exercise 53.5.

(a) Let $k \geq 5$. Determine the abelianization of the permutation group S_k.
(b) Let G be an abelian group, let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be epimorphisms. Show that $A *_G B$ is also abelian.

Exercise 53.6. Given a group G we denote by G_{ab} its abelianization.

(a) Let $\varphi\colon A \to B$ be an epimorphism. Show that the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is also an epimorphism.
(b) Let $\varphi\colon A \to B$ be a monomorphism. Is the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ also a monomorphism?

Exercise 53.7. Let (X, x_0) be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism with $f(x_0) = x_0$. Show that there exists an isomorphism of the following form:
$$\pi_1(\mathrm{Tor}(X, f))_{\mathrm{ab}} \;\cong\; \mathbb{Z} \oplus \mathrm{coker}\left(\pi_1(X, x_0)_{\mathrm{ab}} \xrightarrow{f_* - \mathrm{id}} \pi_1(X, x_0)_{\mathrm{ab}}\right).$$
Remark. Make use of the Mapping Torus-π_1-Proposition 50.6.

Exercise 53.8. Let $\varphi\colon G \to H$ be a group epimorphism. We write $K := \ker(\varphi)$. We consider its abelianization K_{ab}.

(a) Let $h \in G$. We pick $\widetilde{h} \in G$ with $\varphi(\widetilde{h}) = h$. Show that the map
$$\begin{array}{ccc} K_{\mathrm{ab}} & \to & K_{\mathrm{ab}} \\ [k] & \mapsto & [\widetilde{h} \cdot k \cdot \widetilde{h}^{-1}] \end{array}$$
is a group isomorphism and show that this map does not depend on the choice of $\widetilde{h}$.
(b) What goes wrong in (a) if we work with K instead of K_{ab}?

Exercise 53.9. Given any $l, m, n \in \mathbb{N}$. We consider the von Dyck group

$$T(l,m,n) \;:=\; \langle a, b \,|\, a^l, b^m, (ab)^n \rangle.$$

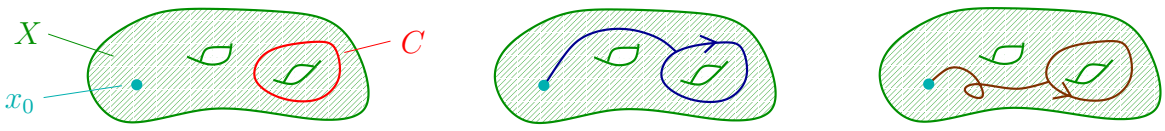
Show that $T(l,m,n)_{\mathrm{ab}} \cong \mathbb{Z}_{\gcd(l,m,n)}$.
Remark. It follows in particular that if l, m, n are coprime, then the abelianization is trivial. If $\frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1$, then it follows from Corollary 66.24 together with Lemma 66.23 that the von Dyck group $T(l,m,n)$ is nonetheless infinite.

Exercise 53.10. Let $\varphi\colon \langle x, y\rangle \to \mathbb{Z}^2$ be the epimorphism that is given by $\varphi(x) = (1,0)$ and $\varphi(y) = (0,1)$. Show that the kernel $\ker(\varphi)$ is normally generated by the commutator $[x,y] = xyx^{-1}y^{-1}$.

Exercise 53.11. Let $\varphi\colon G \to A$ and $\psi\colon G \to B$ group monomorphisms which we use to define the amalgamated product $A *_G B$. Suppose that the map $A \to A *_G B$ is an isomorphism. Show that ψ is an isomorphism.

Exercise 53.12. Let G be a group. Let $\alpha\colon G \to A$ be a monomorphism to a simple group A and let $\beta\colon G \to B$ be an epimorphism that is not an isomorphism. Show that the amalgamated product $A *_G B$ is trivial.

Exercise 53.13. Let A and G be groups and let $\varphi\colon A \to G$ be an epimorphism. Furthermore let G' be a copy of G. We consider the amalgamated product $G *_A G'$ given by using twice the epimorphism $\varphi\colon A \to G$ and $\varphi\colon A \to G' = G$. Show that the natural homomorphism $G \to G *_A G'$ is an isomorphism.



Exercise 53.14.

(a) Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be group homomorphisms and let $\varphi\colon H \to G$ be an epimorphism. Show that the natural map $A *_G B \to A *_H B$ is an isomorphism.
(b) Let $\alpha\colon G * H \to A$ and $\beta\colon G * H$ to be group homomorphisms. We assume that the restriction of β to H is trivial. Show that the natural map $A *_{G*H} B \to A/\langle\langle H \rangle\rangle *_G B$ is an isomorphism.

Exercise 53.15. Let X be a path-connected topological space and let $x_0 \in X$. Furthermore let $C \subset X$ be a subset that is homeomorphic to S^1. We pick a homeomorphism $\varphi\colon S^1 \to C$ and a path $\gamma\colon [0,1] \to X$ from x_0 to $\varphi(1)$. We denote by $\widetilde{\varphi}\colon [0,1] \to X$ the map that is given by $t \mapsto \varphi(\exp(2\pi\,\mathrm{i}\,t))$. Show that the subgroup

$$\langle\langle C \rangle\rangle \;:=\; \langle\langle \gamma * \varphi * \widetilde{\gamma} \rangle\rangle \;\subset\; \pi_1(X, x_0)$$

neither depends on the choice of φ nor on the choice of γ.

Exercise 53.16. Let π be a group and let S be a generating set for π. We set $V := \pi$, we set $E := V \times S$ and we define the initial map $i\colon E = V \times S \to V$ by $i((v,s)) = v$ and we define the terminal map $t\colon E = V \times S \to V$ by $t((v,s)) = v \cdot s$. Note that (V, E, i, t) is an abstract graph. It is called the *Cayley graph* $\Gamma(\pi, S)$ of the group π with respect to the generating set S.

(a) We consider $\pi = \langle x, y \,|\, xyx^{-1}y^{-1} \rangle$ with the generating set $S = \{x, y\}$. Sketch $|\Gamma(\pi, S)|$ as a subset of $\mathbb{R}^2$.
(b) We consider $\pi = \langle x, y \,|\, \varnothing \rangle$ with the generating set $S = \{x, y\}$. Sketch $|\Gamma(\pi, S)|$ as a subset of $\mathbb{R}^2$.
(c) We consider $\pi = \langle x, y \,|\, x^2, xyx^{-1}y^{-1} \rangle$ with the generating set $S = \{x, y\}$. Sketch $|\Gamma(\pi, S|$ as a subset of $\mathbb{R}^3$.

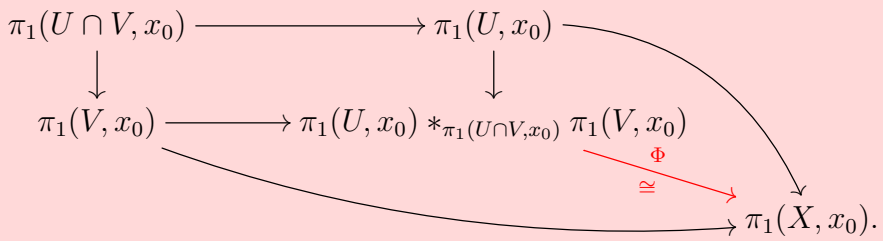
Exercise 53.17. Let $K = \mathbb{R}$ or $K = \mathbb{C}$. Let $n \in \mathbb{N}$.

(a) Show that the abelianization of $\mathrm{SL}(n, \mathbb{K})$ is the trivial group.
Hint. Try to write the elementary matrices as commutators.
(b) Determine the abelianization of $\mathrm{GL}(n, \mathbb{K})$.

Remark. A group with trivial abelianization is sometimes called *perfect*. We have thus shown that the groups $\mathrm{SL}(n, \mathbb{K})$ are perfect.

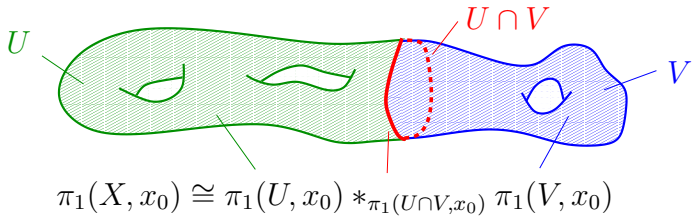
54. The general Seifert–van Kampen Theorem

In this chapter we will generalize the "basic" Seifert–van Kampen Theorem 52.2 to the setting where we no longer need to assume that the intersection $U \cap V$ is simply connected. We will use the resulting Seifert–van Kampen Theorem 54.1 to determine the fundamental groups of the (non-) orientable surfaces Σ_g and N_g. In Chapter 55 we will use these calculations to give the classification of compact 2-dimensional smooth and topological manifolds.



Towards the end of this chapter we will use the Seifert–van Kampen Theorem 54.1 to prove the Fundamental Group-Manifold Realization Proposition 54.12 which says, in a nutshell, that every finitely presented group occurs as the fundamental group of a closed smooth manifold of dimension ≥ 4.

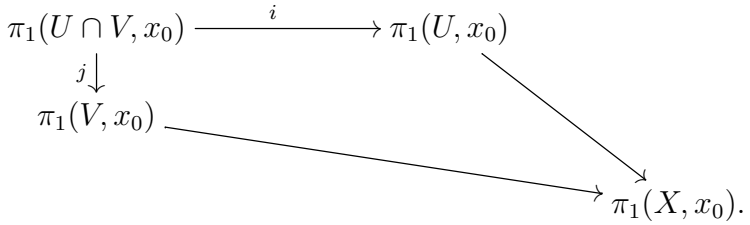
54.1. **The formulation of the general Seifert–van Kampen Theorem.** With the group theoretic preparations from Chapter 53 we can now formulate and prove the general Seifert–van Kampen Theorem.



Theorem 54.1. (Seifert–van Kampen Theorem) Let X be a topological space and let $X = U \cup V$ be a decomposition of X in two open subsets U and V such that $U \cap V$ is non-empty and path-connected. Let $x_0 \in U \cap V$. Then there exists an isomorphism

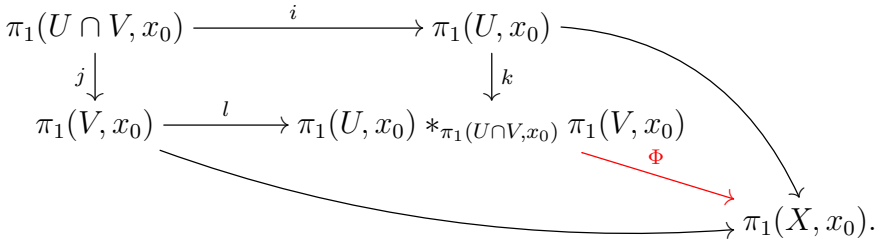
$$\Phi\colon \pi_1(U, x_0) *_{\pi_1(U\cap V, x_0)} \pi_1(V, x_0) \xrightarrow{\cong} \pi_1(X, x_0)$$

such that the following diagram commutes:



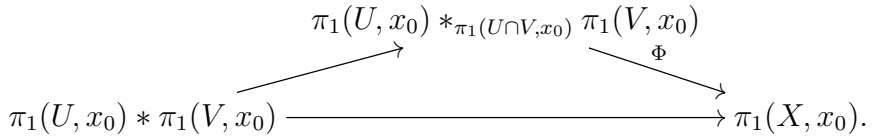
Here all the "undecorated" maps are the obvious inclusion induced homomorphisms.

The proof of the general Seifert–van Kampen Theorem is a modification of the proof of the more "basic" Seifert–van Kampen Theorem 52.2 where we had assumed that $U \cap V$ is in fact simply connected. We only sketch the proof of the general Seifert–van Kampen Theorem 54.1. The full details are for example given in Section 1.2 of [**Hat2002**].



Sketch of the proof. The various inclusions of topological spaces give rise to the following commutative diagram:

By Proposition 53.21 there exists a unique homomorphism



$$\Phi\colon \pi_1(U, x_0) *_{\pi_1(U\cap V, x_0)} \pi_1(V, x_0) \;\to\; \pi_1(X, x_0)$$

such that the following diagram commutes:

It remains to show that Φ is surjective and that Φ is injective.

We first show surjectivity. We consider the following commutative diagram[604] of homomorphisms

By Lemma 52.1 the horizontal map is surjective. It follows that the diagonal map Φ on the right is also surjective.

Now we turn to the proof of the injectivity of Φ. We write $A = \pi_1(U, x_0), B = \pi_1(V, x_0)$ and $G = \pi_1(U \cap V, x_0)$. As on page 1160 we consider the set

$$S(A, B) \;:=\; \{\text{all finite sequences } (x_1, \ldots, x_k) \text{ with each } x_i \text{ in } A \text{ or } B\}.$$

Furthermore we denote by $\sim_G$ the equivalence relation on $S(A, B)$ generated by the relation

$$(x_1, \ldots, x_l, e, x_{l+2}, \ldots, x_k) \;\sim\; (x_1, \ldots, x_l, x_{l+2}, \ldots, x_k)$$

where e is trivial in A or B, by the relation

$$(x_1, \ldots, x_l, x_{l+1}, \ldots, x_k) \;\sim\; (x_1, \ldots, x_l x_{l+1}, \ldots, x_k)$$

if both x_l and x_{l+1} lie in A or both lie in B, and also by the relation

$$(x_1, \ldots, x_l, i(g), x_{l+2}, \ldots, x_k) \;\sim\; (x_1, \ldots, x_l, j(g), x_{l+2}, \ldots, x_k)$$

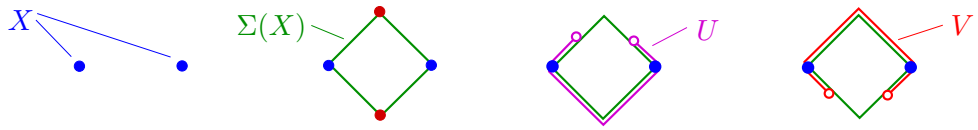
for $g \in G$. Similar to Proposition 51.18 one can now show that the map

$$\begin{array}{rcl} S(A, B)/\!\sim_G & \to & A *_G B \\ [(x_1, \ldots, x_k)] & \mapsto & x_1 \cdot \cdots \cdot x_k \end{array}$$

[604] What are the maps, and why does the diagram commute?

is a well-defined bijection. We will use this isomorphism to identify $S(A,B)/\sim_G$ with $A *_G B$.

The proof of the present theorem is now almost identical to the proof of Theorem 52.2, one just needs to replace the discussion involving $S(A,B)/\sim$ by the corresponding objects in $S(A,B)/\sim_G$. More precisely, in Footnote 569 we pointed out where in the proof of Theorem 52.2 we used the hypothesis that $U \cap V$ is simply connected. At that point in the proof of Theorem 52.2 we need to replace $A * B = S(A,B)/\sim$ with $A *_G B = S(A,B)/\sim_G$. Full details for the proof can be found for example in Section 1.2 of [**Hat2002**]. ■



As a first example we can now prove the following lemma.

Lemma 54.2. (Suspension-π_1-Lemma) If X is a path-connected[605] non-empty topological space, then its suspension[606] $\Sigma(X) = (X \times [-1,1])/\sim$ is simply connected.

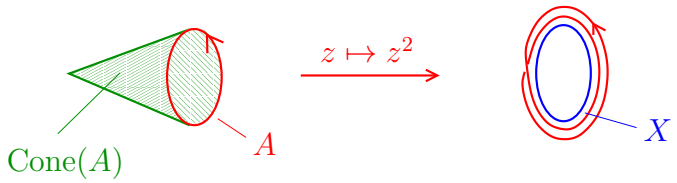
Proof. Let X be a path-connected non-empty topological space. In the following we denote by $p\colon X \times [-1,1] \to \Sigma(X)$ the natural projection. We consider the subsets $U = p(X \times [-1, \frac{1}{2}))$ and $V = p(X \times (-\frac{1}{2}, 1])$. It follows from the definition of the quotient topology on $\Sigma(X)$ that U and V are open subsets of $\Sigma(X)$. We pick a base point x on $X = X \times \{0\} \subset \Sigma(X)$. We calculate that

$$\pi_1(\Sigma(X),x) \underset{\text{Seifert–van Kampen Theorem 54.1}}{\overset{\uparrow}{\cong}} \pi_1(U,x) *_{\pi_1(U\cap V,x)} \pi_1(V,x) \underset{\text{as in the Cone Contractibility Lemma 16.7 we see that } U \text{ and } V \text{ are contractible, hence their fundamental groups are trivial by Homotopy-}\pi_1\text{-Proposition 50.3 (3)}}{\overset{\uparrow}{=}} \underset{\text{of trivial groups}}{\text{amalgamated product}} = \text{trivial group.}$$

We have thus shown that $\Sigma(X)$ is indeed simply connected. ■

The following lemma calculates the fundamental groups of mapping cones, which we introduced on page 457.

Lemma 54.3. (Mapping Cone-π_1-Lemma) Let $f\colon A \to X$ be a map between topological spaces and let $a_0 \in A$. We write $x_0 := f(a_0)$. If A is path-connected, then the inclusion induces an isomorphism



$$\pi_1(X,x_0)/f_*(\pi_1(A,a_0)) \;\to\; \pi_1(\text{Cone}(f\colon A \to X),[x_0]).$$

Example. Let $n \in \mathbb{N}$ and let $A = X = S^1$. We consider the map $f\colon A = S^1 \to X = S^1$ that is given by $f(z) = z^n$. It follows from Lemma 54.3 and Proposition 48.17, perhaps counter-intuitively, that $\pi_1(\text{Cone}(f\colon A \to X)) \cong \mathbb{Z}_n$. We refer to the figure below for an attempt at an illustration of this example.

Proof. We will provide the proof in Exercise 54.1. ■

[605] In Exercise 57.5 we will consider the fundamental group of topological spaces that are not path-connected.

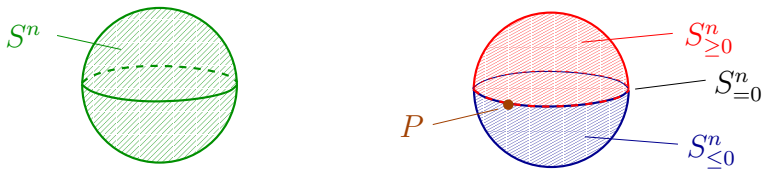
[606] We refer to page 451 for the definition of the suspension of a topological space.

The same way that we deduced Theorem 52.10 from Theorem 52.2 we can now obtain the following theorem from Theorem 54.1.

Theorem 54.4. (Seifert–van Kampen Theorem for Topological Manifolds) Let M be an m-dimensional topological manifold and let $R, S \subset M$ be two m-dimensional submanifolds such that the following hold:

(1) $M = R \cup S$,
(2) $R \cap S$ is a component of ∂R and it is a component of ∂S,
(3) R and S are closed subsets of M.

We pick a base point $x_0 \in R \cap S$. Then the inclusion induced map



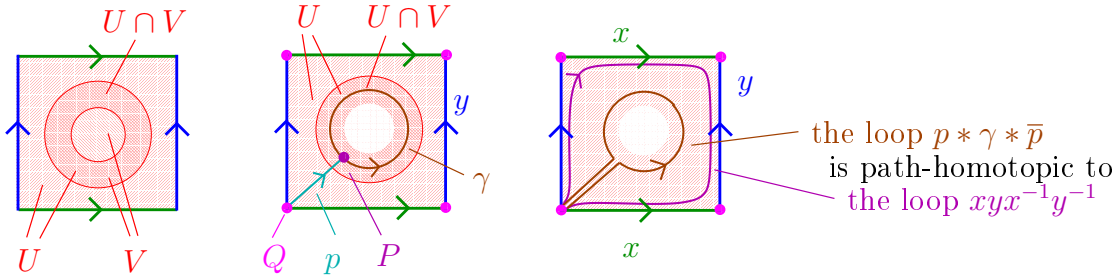
$$\pi_1(R, x_0) *_{\pi_1(R\cap S, x_0)} \pi_1(S, x_0) \;\to\; \pi_1(M, x_0)$$

is an isomorphism.

Example. Given $n \in \mathbb{N}_0$ we denote as usual by $S^n_{\geq 0}$ the upper hemisphere of S^n and we denote by $S^n_{\leq 0}$ the lower hemisphere of S^n. We denote by $S^n_{=0} = S^n_{\geq 0} \cap S^n_{\leq 0}$ the "equator" of S^n, which is of course homeomorphic to S^{n-1}. Given any $n \in \mathbb{N}_{\geq 2}$ and any $P \in S^n_{=0}$ we can perform the following calculation:

$$\pi_1(S^n, P) \;\underset{\text{by the Seifert–van Kampen Theorem 54.4, note that we use that our hypothesis } n\in\mathbb{N}_{\geq 2} \text{ implies that } S^{n-1} \text{ is path-connected}}{\cong}\; \pi_1(S^n_{\leq 0}, P) *_{\pi_1(S^n_{=0},P)} \pi_1(S^n_{\geq 0}, P) \;\underset{\text{by page 152 the hemispheres are homeomorphic to } \overline{B}^n, \text{ hence the fundamental groups are trivial}}{\cong}\; \{e\} *_{\pi_1(S^{n-1},P)} \{e\} \;\underset{\text{by definition or by the Amalgamated Product Lemma 53.22}}{\cong}\; \{e\}.$$

This calculation gives a new, and arguably more conceptual proof of the Sphere-π_1-Proposition 47.13.



54.2. **The fundamental groups of surfaces.** Now we want to use the Seifert–van Kampen Theorem 54.1 to determine the fundamental groups of surfaces of genus $g \geq 2$. Before

we do so we consider the torus, the Klein bottle and the real projective plane to gain some confidence in our newly acquired methods.[607]

(1) We first consider the torus $T = ([0,1] \times [0,1])/\sim$. In the following we will use the following notation, see also the figure below for an illustration:
   (a) We denote by Q the point on T corresponding to the four vertices of the square.
   (b) We write $T = U \cup V$ where

$$U = T \setminus \overline{B_{\frac{1}{8}}(\tfrac{1}{2},\tfrac{1}{2})} \subset T \quad \text{and } V = B_{\frac{1}{4}}(\tfrac{1}{2},\tfrac{1}{2}) \subset T,$$

   i.e. U is the complement of a closed disk and V is an open disk and $U \cap V$ is an open annulus.
   (c) We let $P = (r,r) \in U \cap V$ and we denote by p the direct path from Q to P.
   (d) We pick a loop γ in $(U \cap V, P)$ that "goes counterclockwise around the annulus" and that represents a generator of the infinite cyclic group $\pi_1(U \cap V, P) \cong \mathbb{Z}$.[608]
   (e) We denote by x and y the two loops in (T,Q) corresponding to the horizontal and the vertical edge of the square. By a slight abuse of notation we denote the corresponding elements in $\pi_1(T,Q)$ by x and y as well.

Now we have

$$\begin{array}{lll}
\pi_1(T,P) & \cong & \pi_1(U,P) *_{\pi_1(U\cap V,P)} \pi_1(V,P) \\
\uparrow & & \\
\text{Seifert–van Kampen Theorem 54.1} & & \\
& = & \pi_1(U,P)/\langle\langle i_*(\pi_1(U\cap V,P))\rangle\rangle \\
& \uparrow & \\
& \text{by the Amalgamated Product Lemma 53.22} & \\
& \text{we have } A *_G \{e\} = A/\langle\langle \alpha(G)\rangle\rangle & \\
& \xrightarrow[\uparrow]{\cong} & \pi_1(U,Q)/\langle\langle [p*\gamma*\overline{p}]\rangle\rangle \\
& & \text{by the Change-of-Base Point Proposition 47.10} \\
& & \text{path } p \text{ gives rise to an isomorphism } p_*
\end{array}$$

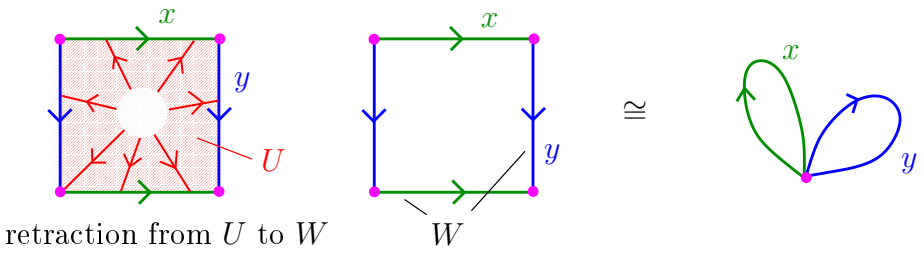
$$\begin{array}{lll}
= \pi_1(U,P) *_{\pi_1(U\cap V,P)} \{e\} & & \\
\uparrow & & \\
V \text{ is a disk, hence } \pi_1(V,P) = \{e\} & & \\
= \pi_1(U,P)/\langle\langle [\gamma]\rangle\rangle & & \\
\uparrow & & \\
\text{since } \pi_1(U\cap V,P) = \langle[\gamma]\rangle & & \\
= \pi_1(U,Q)/\langle\langle xyx^{-1}y^{-1}\rangle\rangle = (*). & & \\
\uparrow & & \\
\text{since } p*\gamma*\overline{p} \text{ is path-homotopic to } xyx^{-1}y^{-1} & &
\end{array}$$

As in the proof of Lemma 52.9 we can show that $W := \partial([0,1] \times [0,1])/\sim$ is a deformation retract of U and that W is homeomorphic to the wedge of two circles. By the Fundamental Group-Wedge-of-Circles Lemma 52.4 we can therefore make the identification $\pi_1(W,P) = \langle x, y\rangle$, see also the figure below. Now we continue with the

[607] The following examples can also be handled using Theorem 54.4 instead of Theorem 54.1. The advantage of using Theorem 54.1 at this point is that in the illustrations one can draw $U \cap V$ better if U and V are open subsets.

[608] Since $U \cap V$ is an open annulus its fundamental group is isomorphic to $\mathbb{Z}$.

above calculation of $\pi_1(T,P)$. We have



$$(*) \;=\; \pi_1(U,Q)/\langle\langle xyx^{-1}y^{-1}\rangle\rangle \;\overset{\cong}{\underset{\uparrow}{\to}}\; \pi_1(W,P)/\langle\langle xyx^{-1}y^{-1}\rangle\rangle$$

by the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2)

$$\underset{\uparrow}{=}\; \langle x,y\rangle/\langle\langle xyx^{-1}y^{-1}\rangle\rangle \;=\; \langle x,y \mid [x,y]\rangle \;\underset{\uparrow}{\cong}\; \mathbb{Z}^2.$$

since W is the wedge of the circles x and y — see Lemma 53.6 (1)

Thus we have reproved that the fundamental group of the torus is isomorphic to the free abelian group $\mathbb{Z}^2$.

retraction from U to W

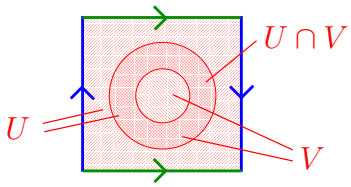
(2) We turn to the Klein bottle K. The approach to calculating the fundamental group of the Klein bottle is almost identical to the above approach to calculating the fundamental group of the torus. We just replace the situation illustrated in the figure above by the situation illustrated in the figure below. The same argument as above shows that[609]

$$\pi_1(K) \;\cong\; \langle x,y \mid yxyx^{-1}\rangle.$$

Using this presentation and using the Abelianization Proposition 53.20 (5) we obtain in particular that the abelianization of $\pi_1(K)$ is given by

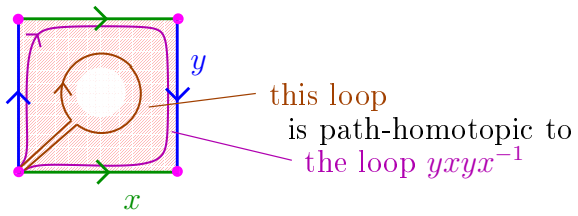
$$\pi_1(K)_{\text{ab}} \;\cong\; \langle x,y \mid yxyx^{-1}\rangle_{\text{ab}} \;\cong\; \mathbb{Z}^2/\tbinom{0}{2}\mathbb{Z} \;\cong\; \mathbb{Z}\oplus\mathbb{Z}_2.$$

On page 1091 we already gave a very different calculation of $\pi_1(K)$. More precisely, we introduced the group G that is given by all self-homeomorphisms of $\mathbb{R}^2$ that can be written as concatenations of the two self-homeomorphisms



$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s+1,1-t) \end{array} \quad\text{and}\quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s,t+1) \end{array}$$

and their inverses and we showed that $\pi_1(K)\cong G$. On page 1195 we already showed that there exists a homomorphism $\Phi\colon \langle x,y \mid yxyx^{-1}\rangle \to G$ with $\Phi(x)=B^{-1}A$ and $\Phi(y)=B$. This homomorphism is in fact an isomorphism. This can be seen as follows. Denote by H the group of all self-homeomorphisms of $\mathbb{R}^2$. We consider the diagram



$$\langle x,y \mid yxyx^{-1}\rangle \xrightarrow{\;\cong\;} \pi_1(K) \xleftarrow{\;\cong\;} \text{subgroup of } H \text{ generated by } A,B.$$
$$\langle x,y \mid yxyx^{-1}\rangle \xrightarrow[x\mapsto B^{-1}A,\,y\mapsto B]{\;\Phi\;} \text{subgroup of } H \text{ generated by } A,B.$$

[609] In particular this shows that $\pi_1(K)$ is finitely presented. This answers the question we had raised on page 1196.

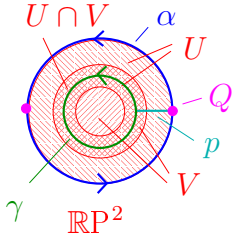
Here the isomorphisms to $\pi_1(K)$ are the ones given by the two calculations of the fundamental group. If one goes carefully through the definitions of the two horizontal maps, then one can see that the diagram commutes. Since two of the three maps are isomorphisms and since the diagram commutes it follows that Φ is also an isomorphism.

the Klein bottle

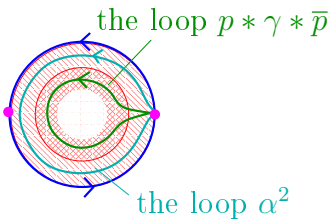
(3) Next we consider again the real projective space $\mathbb{R}\mathrm{P}^2$. Here we use the description of $\mathbb{R}\mathrm{P}^2$ from Lemma 5.32 as

$$\mathbb{R}\mathrm{P}^2 \;=\; \overline{B}^2/\!\sim \qquad \text{where for } z \in S^1 \text{ we have } z \sim -z.$$

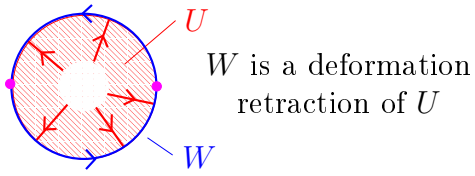
As in the previous two examples we decompose $\mathbb{R}\mathrm{P}^2$ into an open disk V and the complement of a closed disk U such that $U \cap V$ is an annulus. We consider the base point $Q = [1] = [-1] \in \mathbb{R}\mathrm{P}^2$ and we denote by α the loop



$$\begin{array}{rcl} \alpha\colon [0,1] & \to & \mathbb{R}\mathrm{P}^2 \\ t & \mapsto & [\exp(\mathrm{i}\pi t)]. \end{array}$$



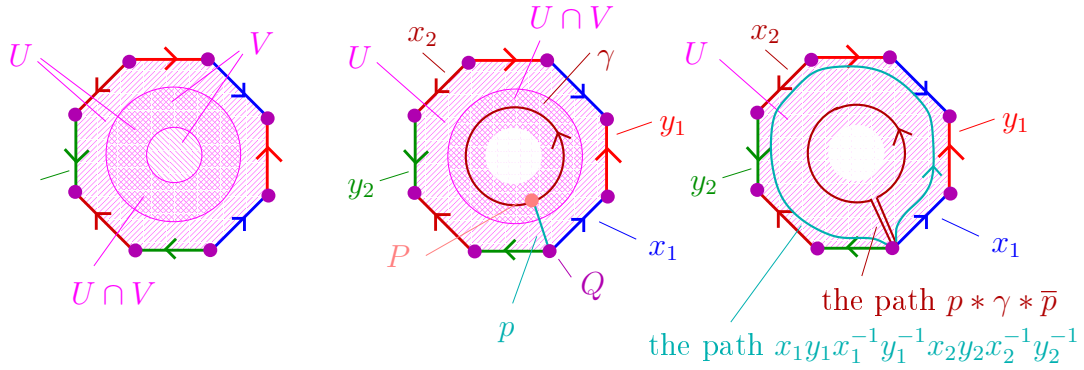
By a slight abuse of notation we now denote by α also the corresponding element in $\pi_1(\mathbb{R}\mathrm{P}^2, Q)$. Furthermore we denote by W the image of α in $\mathbb{R}\mathrm{P}^2$. Evidently α is a generator of $\pi_1(W, Q)$. Then, with similar arguments as in the torus case, we see that



$$\pi_1(\mathbb{R}\mathrm{P}^2) \;\underset{\uparrow}{\cong}\; \pi_1(U,Q)/\langle\langle p*\gamma*\overline{p}\rangle\rangle \;\underset{\uparrow}{\cong}\; \pi_1(W,Q)/\langle\langle p*\gamma*\overline{p}\rangle\rangle \;\underset{\uparrow}{\cong}\; \langle\alpha\rangle/\langle\alpha^2\rangle \;\cong\; \mathbb{Z}_2.$$

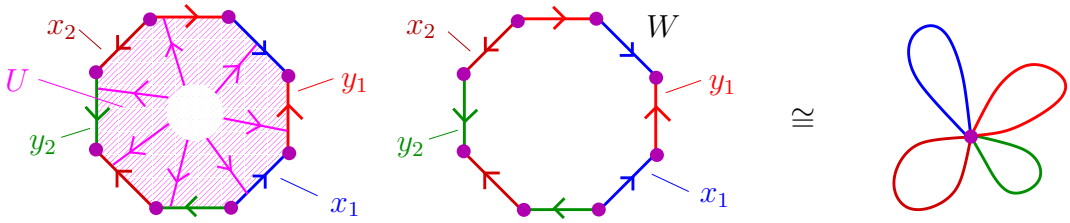
by the Seifert–van Kampen Theorem 54.1 and Amalgamated Product Lemma 53.22 (2) — since W is a deformation retract of U — since $\pi_1(W,Q) = \langle\alpha\rangle$ and $[p*\gamma*\overline{p}] = \alpha^2$

In particular we obtain the same result, as we should, as in Corollary 48.18.



(4) Now that we have gained some confidence that the approach of determining fundamental groups using Seifert–van Kampen Theorem 54.1 does indeed give the right fundamental groups we turn to the surfaces of higher genus that we could not handle with our previous methods.

So let us consider the surface $F = E_8/\!\sim$ of genus 2. As in the torus case we write $F = U \cup V$ where V is an open disk and where U is the complement of a closed disk such that $U \cap V$ is an annulus. Similar to the torus case we write $W = \partial E_8/\!\sim$. By the proof of Proposition 52.8 we know that W is a deformation retraction of U and



that W is homeomorphic to the wedge of four circles corresponding to x_1, y_1, x_2, y_2. See also the figures below for an illustration. Basically exactly the same argument

as in the torus case shows that

$$\begin{aligned}\pi_1(E_8/\!\sim, P) &\cong \pi_1(U,Q)/\langle\langle \overbrace{x_1y_1x_1^{-1}y_1^{-1}x_2y_2x_2^{-1}y_2^{-1}}^{\text{path-homotopic to } p*\gamma*\overline{p}} \rangle\rangle \\ &\qquad\qquad \underbrace{\qquad\qquad\qquad\qquad\qquad\qquad}_{=[x_1,y_1][x_2,y_2]} \\ &\cong \pi_1(W,Q)/\langle\langle [x_1,y_1][x_2,y_2]\rangle\rangle \\ &\cong \langle x_1,y_1,x_2,y_2\rangle/\langle\langle [x_1,y_1][x_2,y_2]\rangle\rangle \;=\; \langle x_1,y_1,x_2,y_2 \mid [x_1,y_1][x_2,y_2]\rangle.\end{aligned}$$

Thus we have finally succeeded in calculating the fundamental group of the surface of genus 2.

The following gives in particular a new proof for Proposition 52.8.

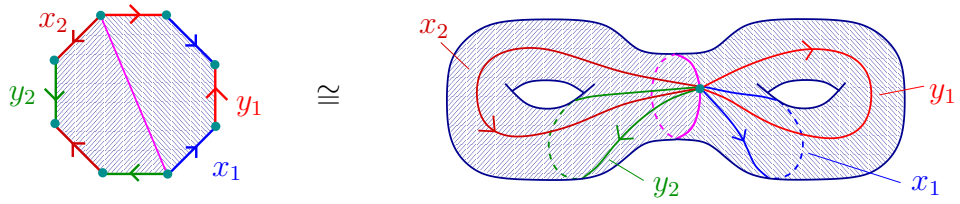
Proposition 54.5. (Fundamental Group-of-Surfaces Proposition)

(1) For any $g \in \mathbb{N}_0$ we have

$$\pi_1(\text{surface } \Sigma_g \text{ of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1,y_1]\cdot\cdots\cdot[x_g,y_g]\rangle$$

and we have $\pi_1(\text{surface of genus } g)_{\text{ab}} \;\cong\; \mathbb{Z}^{2g}$.

(2) For $g \neq h$ the surfaces of genus g and h are not homeomorphic.



Proof.

(1) Let $g \in \mathbb{N}_0$. For $g = 0$ we obtain the fundamental group from the Sphere-π_1-Proposition 47.13 and for $g = 1$ we obtain the presentation from the discussion on page 1221. For $g \geq 2$ the presentation follows from a straightforward generalization of the calculation preceding the proposition. Finally the stated abelianization of the fundamental group is an immediate consequence of the Abelianization Proposition 53.20 (5).

(2) For $g \neq h$ we obtain from the Finitely Generated Abelian Group Classification Theorem 51.4 that the abelianizations of the fundamental groups of the surfaces of genus g and h are not isomorphic. Hence the surfaces are not homeomorphic. ■

Remark.

(1) In the figure below we show loops that represent the generators x_1, y_1, x_2, y_2 of the fundamental group for the surface of genus 2.

(2) As explained in the figure on page **??** we can view the surface Σ of genus 2 as the connected sum of two copies of the torus T. We can also use this point of view to determine the fundamental group of the surface Σ of genus 2. More precisely, we have $\Sigma = F_1 \cup F_1$ with $F_1 = T \setminus B^2$ and $F_2 = T \setminus B^2$ where $F_1 \cap F_2 = \partial F_1 = \partial F_2 \cong S^1$ and we obtain that[610]

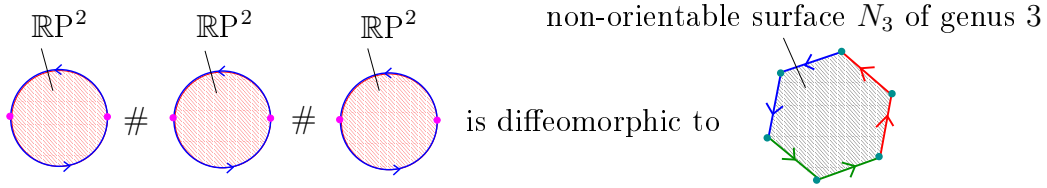
$$\begin{array}{l} \text{Seifert–van Kampen Theorem 54.4} \qquad\qquad \text{by Lemma 52.9 (2) where } t \mapsto [x_1, y_1] \text{ and } t \mapsto [x_2, y_2] \\ \pi_1(\Sigma) \overset{\downarrow}{\cong} \pi_1(F_1) *_{\pi_1(F_1 \cap F_2)} \pi_1(F_2) \overset{\downarrow}{\cong} \langle x_1, y_1 \rangle *_{\langle t \rangle} \langle x_2, y_2 \rangle \\ \quad \cong \langle x_1, x_2, y_1, y_2 \mid [x_1, y_1] = [x_2, y_2] \rangle. \\ \quad \uparrow \\ \quad \text{see page 1211} \end{array}$$

Let $g \geq 2$ and let π be the fundamental group of the surface of genus g. We have just shown that $\pi_{\text{ab}} \cong \mathbb{Z}^{2g}$. This raises the question, whether perhaps π is isomorphic to $\mathbb{Z}^{2g}$ or to the free group F_{2g} on $2g$ generators. The proof of the following lemma is Exercise 54.2.

Lemma 54.6. The group $\pi = \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle$ is non-abelian.

The lemma says in particular that π is not isomorphic to $\mathbb{Z}^{2g}$. It is much harder to determine whether or not π is a free group. We record this as a question for later.

Question 54.7. Let π be the fundamental group of the surface of genus g. Is π isomorphic to the free group F_{2g} on $2g$ generators?



We will give an answer to the question in Proposition 64.17 and also on page 1887.
Let π be the fundamental group of the surface of genus g. In Exercise 54.4 we will see that if $g \geq 2$, then π contains a free group on two generators as a subgroup. This raises the question, what other groups can occur as subgroups of π? Let us record this as a question.

Question 54.8. Let π be the fundamental group of the surface of genus g. What isomorphism types of subgroups can appear? Is every subgroup again a free group or the fundamental group of a surface?

We will provide the answer to Question 54.8 in the Subgroups-of-Surface Groups Proposition 64.6.

[610] Why is this group isomorphic to the above group $\langle x_1, y_1, x_2, y_2 \mid [x_1, y_1][x_2, y_2] \rangle$?

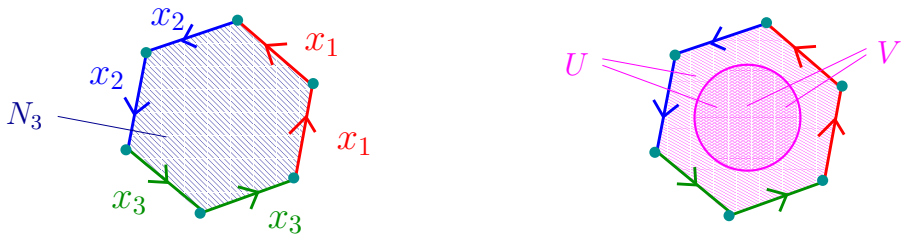
54.3. **Non-orientable surfaces.** In this section we will discuss the fundamental groups of the non-orientable surfaces N_g of some genus $g \in \mathbb{N}$. It is also worth recalling that in Exercise **??** we showed that the connected sum of g copies of $\mathbb{R}\mathrm{P}^2$ is diffeomorphic to the non-orientable surface of genus g that we introduced on page 266.

The following proposition is the analogue of the Fundamental Group-of-Surfaces Proposition 54.5.

Proposition 54.9. (Fundamental Group-of-Surfaces Proposition II)

(1) For any $g \in \mathbb{N}$ we have

$$\pi_1(\text{non-orientable surface } N_g \text{ of genus } g) \;\cong\; \langle x_1, \ldots, x_g \mid x_1^2 \cdot \cdots \cdot x_g^2 \rangle$$



and we have

$$\pi_1(\text{non-orientable surface } N_g \text{ of genus } g)_{\mathrm{ab}} \;\cong\; \mathbb{Z}^{g-1} \oplus \mathbb{Z}_2.$$

(2) For $g \neq h$ the non-orientable surfaces of genus g and h are not homeomorphic.

Proof.

(1) Let $g \in \mathbb{N}$. Recall that the non-orientable surface of genus one is by definition the real projective plane. In Corollary 48.18 we saw that $\pi_1(\mathbb{R}\mathrm{P}^2) \cong \mathbb{Z}_2 \cong \langle x \,|\, x^2 \rangle$. The case $g \geq 2$ follows from a straightforward modification of the calculation of the fundamental group of the surface of genus 2 that we gave on page 1224. Using the figure below the reader should have no troubles with assembling a full argument. Finally note that the stated abelianization of the fundamental group is an immediate consequence of the Abelianization Proposition 53.20 (5).

(2) For $g \neq h$ we obtain from the above calculation and from the Finitely Generated Abelian Group Classification Theorem 51.4 that the abelianizations of the fundamental groups of the non-orientable surfaces of genus g and h are not isomorphic. Hence the non-orientable surfaces of genus g and h are not homeomorphic. ■

As mentioned above, in Exercise **??** we showed that for any $g \in \mathbb{N}$ the non-orientable surface of genus g is diffeomorphic to the connected sum of g copies of $\mathbb{R}\mathrm{P}^2$. In particular the Klein bottle is diffeomorphic to $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$. Just for fun and for practice we provide the direct calculation of the fundamental group of $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ using the Seifert–van Kampen

Theorem 54.4 for Smooth Manifolds. The calculation is somewhat interesting since it involves some interesting maps between fundamental groups.

Lemma 54.10. $\pi_1(\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2) \cong \langle x, y \mid x^2 = y^2\rangle$.

Proof. In order to distinguish the two copies of $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$ we write $P = \mathbb{R}\mathrm{P}^2$ and $Q = \mathbb{R}\mathrm{P}^2$. The proof is of course a variation on the proof of the Connected Sum-π_1-Proposition 52.12. We have

$$\pi_1(\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2) = \pi_1(P\#Q) \underset{\uparrow}{\cong} \pi_1\big(P \setminus \tfrac{1}{2}B^2\big) *_{\pi_1(\frac{1}{2}S^1)} \pi_1\big(Q \setminus \tfrac{1}{2}B^2\big).$$

by the definition of $P\#Q$ and the Seifert–van Kampen Theorem 54.4

We pick a generator g for $\pi_1(\frac{1}{2}S^1)$. In the calculation of the fundamental group of the real projective plane on page 1223 we saw that $\pi_1(P \setminus \frac{1}{2}B^2) \cong \langle x\rangle$ and that the inclusion induced map $\pi_1(\frac{1}{2}S^1) \to \pi_1(P \setminus \frac{1}{2}B^2)$ is given by $g \mapsto x^2$. Evidently the same holds for Q with $\pi_1(Q \setminus \frac{1}{2}B^2) \cong \langle y\rangle$. Summarizing we see that

$$\begin{aligned}
\pi_1(\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2) &\cong \pi_1\big(P \setminus \tfrac{1}{2}B^2\big) *_{\pi_1(\frac{1}{2}S^1)} \pi_1\big(Q \setminus \tfrac{1}{2}B^2\big) \\
&\cong \text{amalgamated product of } \begin{pmatrix} \langle g\rangle & \to & \langle x\rangle \\ g & \mapsto & x^2 \end{pmatrix} \text{ and } \begin{pmatrix} \langle g\rangle & \to & \langle y\rangle \\ g & \mapsto & y^2 \end{pmatrix} \\
&\underset{\uparrow}{\cong} \langle x, y \mid x^2 = y^2\rangle = \langle x, y \mid x^2y^{-2}\rangle.
\end{aligned}$$

Lemma 53.23

We have thus shown that $\pi_1(\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2) \cong \langle x, y \mid x^2 = y^2\rangle$. ∎

We conclude this section with a short discussion of the properties of fundamental groups of compact 2-dimensional smooth manifolds. We recall that the fundamental group of the real projective space $\mathbb{R}\mathrm{P}^2$ is isomorphic to $\mathbb{Z}_2$, therefore it is torsion and in particular it is not torsion-free. It is less clear whether or not the fundamental groups of the other 2-dimensional smooth manifolds are torsion-free. More precisely, we have the following question.

Question 54.11.

(1) Let $g \in \mathbb{N}$. Is the fundamental group

$$\pi_1(\text{surface of genus } g) \cong \langle x_1, y_1, \dots, x_g, y_g \mid [x_1, y_1] \cdot \dots \cdot [x_g, y_g]\rangle$$

torsion-free?

(2) Let $k \geq 2$. Is the fundamental group

$$\pi_1(k \cdot \mathbb{R}\mathrm{P}^2) \cong \langle x_1, \dots, x_k \mid x_1^2 \cdot \dots \cdot x_k^2\rangle$$

torsion-free?

We will come back to this question in Exercise 56.12, Corollary 64.7 and Proposition **??**.

54.4. **Fundamental groups of high-dimensional smooth manifolds.** Later on, in the Smooth Manifolds-Invariants Proposition 96.6 we will see that the fundamental group of a compact connected smooth manifold is necessarily finitely presented. In this section we want to study the converse: which finitely presented groups can occur as fundamental groups of smooth manifolds?

First note that it follows from the Smooth 1-Dimensional Manifold Classification Theorem 22.7 that only the trivial group and $\mathbb{Z}$ occur as the fundamental group of a compact connected 1-dimensional topological manifold. Similarly, we will see shortly in Theorem 55.4 that only "few" finitely presented groups occur as the fundamental group of compact connected 2-dimensional topological manifold. In contrast we will now see that once we go to dimension ≥ 4 any finitely presented group occurs as the fundamental group of a closed orientable smooth manifold

Proposition 54.12. (Fundamental Group-Manifold Realization Proposition) Let π be a finitely presented group. Given any $n \geq 4$ there exists a closed orientable connected non-empty n-dimensional smooth manifold M with $\pi_1(M) \cong \pi$.

Remark.

(1) We will give an alternative proof of the Fundamental Group-Manifold Realization Proposition 54.12 on page 3031.
(2) the Fundamental Group-Manifold Realization Proposition 54.12 is a key ingredient of the proof of the fact, stated in Theorem 60.4, that closed smooth manifolds of a fixed dimension ≥ 4 cannot be classified.

The proof of the Fundamental Group-Manifold Realization Proposition 54.12 relies on two lemmas and one theorem. The first lemma is actually quite interesting in its own right.

Lemma 54.13. Let W be a connected n-dimensional smooth manifold. Suppose we are given $k \in \mathbb{N}_0$ and a submanifold of the form $\overline{B}^{n-k} \times K$ where K is diffeomorphic to S^k.

(1) If $n \geq k+3$, then for every base point $w_0 \in W \setminus (B^{n-1} \times K)$ the inclusion induced map $\pi_1(W \setminus (B^{n-1} \times K), w_0) \to \pi_1(W, w_0)$ is an isomorphism.
(2) If $n = k+2$, then for every base point $w_0 \in W \setminus (B^{n-1} \times K)$ the inclusion induced map $\pi_1(W \setminus (B^{n-1} \times K), w_0) \to \pi_1(W, w_0)$ is an epimorphism.

Proof of Lemma 54.13. We write $X = W \setminus (B^{n-k} \times K)$. Note that it follows from Proposition 47.20 that it suffices to prove the statement for some base point $w_0 \in S^{n-k-1} \times K$.

First we consider the case that $n \geq k+3$. Next note that we have the following two isomorphisms:

$$\pi_1(X, w_0) \underset{\uparrow}{\xrightarrow{\cong}} \pi_1(X, w_0) *_{\pi_1(S^{n-k-1} \times K, w_0)} \pi_1\big(\overline{B}^{n-k} \times K, w_0\big) \underset{\uparrow}{\xrightarrow{\cong}} \pi_1(W, w_0).$$

map is an isomorphism by Lemma 53.22 (3a) and since map $\pi_1(S^{n-k-1} \times K, w_0) \to \pi_1(\overline{B}^{n-k} \times K, w_0)$ is an isomorphism, note that for the latter statement we used that $n \geq k+3$

by the Seifert–van Kampen Theorem 54.4, which we can apply by Proposition 24.16

Since the horizontal maps are induced by the inclusions we see that the inclusion induced map $\pi_1(X, w_0) \to \pi_1(W, w_0)$ is indeed an isomorphism.

If $n = k+2$, then the inclusion induced map $\pi_1(S^{n-k-1} \times K) \to \pi_1(\overline{B}^{n-k} \times K)$ is an epimorphism but no longer an isomorphism. If we now use the Amalgamated Product Lemma 53.22 (3b) instead of the Amalgamated Product Lemma 53.22 (3a) we see that $\pi_1(X, w_0) \to \pi_1(W, w_0)$ is at the very least an epimorphism. ■

Lemma 54.14. Let W be an n-dimensional smooth manifold and suppose we are given a boundary component of the form $S^{n-2} \times C$ where C admits a diffeomorphism $\varphi\colon S^1 \to C$. We set

$$X \;:=\; (W \sqcup (S^{n-2} \times \overline{B}^2))/\!\sim \qquad \text{where } (x, \varphi(y)) \sim (x, y) \text{ for } (x, y) \in S^{n-2} \times S^1.$$

If $n \geq 4$, then for any $w_0 \in W$ the inclusion induced map $\pi_1(W, w_0) \to \pi_1(X, w_0)$ induces an isomorphism[611]

$$\pi_1(W, w_0)/\langle\!\langle C \rangle\!\rangle \xrightarrow{\cong} \pi_1(X, w_0).$$

Proof. Note that it follows from Proposition 47.20 that it suffices to prove the statement for some base point $w_0 \in S^{n-2} \times C$. Next note that we have the following two isomorphisms:

$$\pi_1(W, w_0)/\langle\!\langle C \rangle\!\rangle \xrightarrow[\uparrow]{\cong} \pi_1(W, w_0) *_{\pi_1(S^{n-2}\times C, w_0)} \pi_1\big(S^{n-2} \times \overline{B}^2, w_0\big) \xrightarrow[\uparrow]{\cong} \pi_1(X, w_0).$$

map is an isomorphism by the Amalgamated Product Lemma 53.22 (2), hereby we use that $\pi_1(S^{n-2} \times \overline{B}^2, w_0) = 0$ and that $\pi_1(S^{n-2} \times C, w_0) = \langle C \rangle$, note that for the latter statement we used that $n \geq 4$

by the Seifert–van Kampen Theorem 54.4 which we can apply by the Gluing-Smooth Manifolds-Proposition

Since the horizontal maps are induced by the inclusions we see that the inclusion induced map $\pi_1(W, w_0)/\langle\!\langle C \rangle\!\rangle \to \pi_1(X, w_0)$ is indeed an isomorphism. ∎

Now we are fully equipped for proving the Fundamental Group-Manifold Realization Proposition 54.12.

Proof of the Fundamental Group-Manifold Realization Proposition 54.12. Throughout the proof we will mostly ignore base points. But at the end of the proof we will argue, why being a little sloppy with base points in between does not affect the outcome.

Let $\pi = \langle g_1, \ldots, g_k \,|\, r_1, \ldots, r_l \rangle$ be a finitely presented group. Furthermore let $n \geq 4$. We consider

$$X \;:=\; \underbrace{(S^1 \times S^{n-1}) \# \ldots \# (S^1 \times S^{n-1})}_{k \text{ copies of } S^1 \times S^{n-1}}.$$

It follows basically from the Connected Sum-Proposition **??** that X is a closed orientable connected n-dimensional smooth manifold.

We see that

$$\pi_1(\overbrace{(S^1 \times S^{n-1}) \# \ldots \# (S^1 \times S^{n-1})}^{=X}) \xrightarrow[\uparrow]{\cong} \pi_1(S^1 \times S^{n-1}) * \ldots * \pi_1(S^1 \times S^{n-1}) \xrightarrow[\uparrow]{\cong} \overbrace{\langle g_1 \rangle * \ldots * \langle g_k \rangle}^{=\langle g_1, \ldots, g_k \rangle}.$$

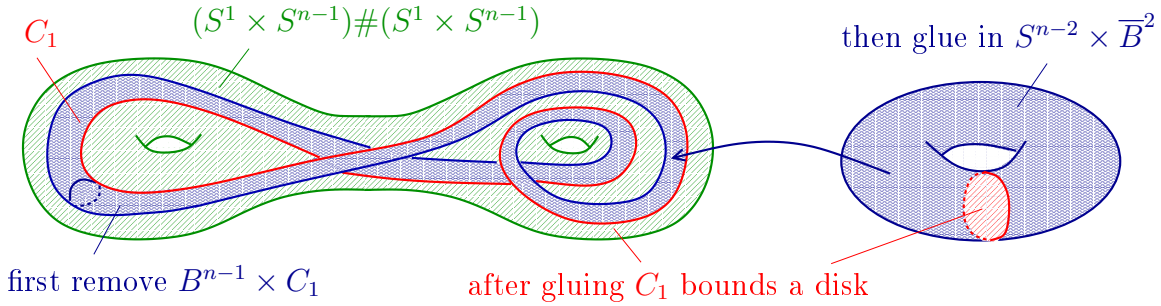
by the Connected Sum-π_1-Proposition 52.12 since $n \geq 3$

by the discussion on page 1093 we know that $\pi_1(S^1 \times S^{n-1}) \cong \mathbb{Z}$

We use this isomorphism to make the identification $\pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle$. Next we pick loops $b_1, \ldots, b_l\colon (S^1, *) \to (X, x_0)$ that represent $r_1, \ldots, r_l \in \pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle$.

By hypothesis we have $\dim(X) = n \geq 4$. Thus we can apply Theorem **??** and we obtain that the map $b_1 \sqcup \cdots \sqcup b_l\colon S^1 \sqcup \cdots \sqcup S^1 \to X$ is in fact homotopic to a smooth embedding $c_1 \sqcup \cdots \sqcup c_l\colon S^1 \sqcup \cdots \sqcup S^1 \to X$. For $i = 1, \ldots, l$ we write $C_i := c_i(S^1)$. It follows from the Smooth Embedding Theorem 24.10 and the Tubular Neighborhood Theorem **??** that we

[611] Here we use that Exercise 53.15 tells us that $C = \{0\} \times C$ gives us a well-defined normal subgroup $\langle\!\langle C \rangle\!\rangle$.



can thicken up the C_i to disjoint submanifolds $\overline{B}^{n-1} \times C_1, \ldots, \overline{B}^{n-1} \times C_l$. We consider[612]

$$Y := X \setminus \bigcup_{i=1}^{l} (B^{n-1} \times C_i) \quad \text{and} \quad Z := \Big(Y \sqcup \bigsqcup_{i=1}^{l} (S^{n-2} \times \overline{B}^2_i) \Big) / \sim \qquad \begin{array}{l} \text{where } (x, c_i(y)) \sim (x, y) \text{ for} \\ x \in S^{n-2} \text{ and } y \in S^1_i = S^1. \end{array}$$

It follows from the Codimension-Zero Smooth Embedding Proposition 24.16 and the Gluing-Smooth Manifolds-Proposition **??** that Z is indeed a closed oriented connected n-dimensional smooth manifold. Finally we see that

$$\begin{array}{ccccc} & \text{Lemma 54.14 applied } l \text{ times} & & \text{Lemma 54.13 applied } k \text{ times} & \\ & \downarrow & & \downarrow & \\ \pi_1(Z) & \cong & \pi_1(Y)/\langle\langle C_1, \ldots, C_l \rangle\rangle & \cong & \pi_1(X)/\langle\langle C_1, \ldots, C_l \rangle\rangle \\ & \cong & \langle g_1, \ldots, g_k \rangle / \langle\langle x_1 r_1 x_1^{-1}, \ldots, x_l r_l x_l^{-1} \rangle\rangle & \cong & \underbrace{\langle g_1, \ldots, g_k \rangle / \langle\langle r_1, \ldots, r_l \rangle\rangle}_{= \langle g_1, \ldots, g_k \,|\, r_1, \ldots, r_l \rangle}. \\ & \uparrow & & \uparrow & \\ & \text{by the above, the } x_i \text{ are necessary since} & & \text{by Lemma 53.2 (5)} & \\ & \text{we lost track of the base points} & & & \end{array}$$

We have thus found the promised smooth manifold. ■

In the proof of the Fundamental Group-Manifold Realization Proposition 54.12 we used on several occasions that we are dealing with dimensions ≥ 4. The following question arises naturally.

Question 54.15. Is every finitely presented group the fundamental group of a closed (or at least compact) orientable connected 3-dimensional smooth manifold?

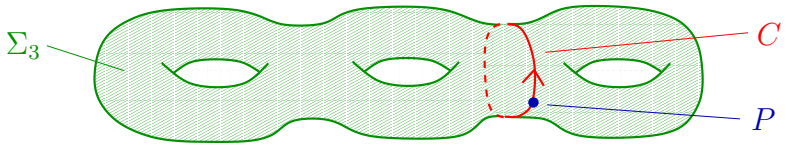
We will answer Question 54.15 in Theorem 146.5.

Exercises for Chapter 54.

Exercise 54.1. Let $f\colon A \to X$ be a map between topological spaces and let $a_0 \in A$. We write $x_0 := f(a_0)$. We suppose that A is path-connected. Show that the natural inclusion map $X \to \mathrm{Cone}(f\colon A \to X))$ induces an isomorphism

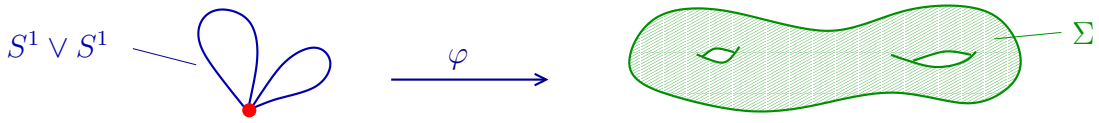
$$\pi_1(X, x_0)/f_*(\pi_1(A, a_0)) \;\to\; \pi_1(\mathrm{Cone}(f\colon A \to X)).$$

Exercise 54.2. Let $g \in \mathbb{N}_{\geq 2}$. We consider the group



$$\pi \;:=\; \pi_1(\text{surface of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \,|\, [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle.$$

[612] The smooth manifold Y is effectively obtained from $(S^1 \times S^{n-1}) \# \ldots \# (S^2 1 \times S^{n-2})$ by removing copies of $\overline{B}^{n-1} \times S^1$ and gluing in copies of $S^{n-2} \times \overline{B}^2$. This operation is frequently called a surgery. We will discuss surgeries in greater detail in Chapter **??**.

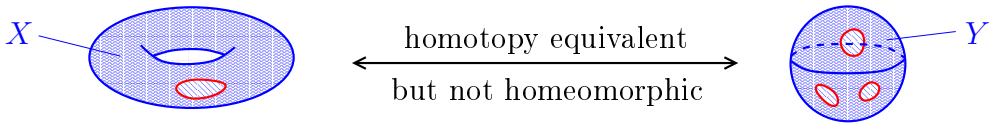


(a) Show that π admits an epimorphism onto a free group of rank ≥ 2.
(b) What is the largest $k \in \mathbb{N}$ for which you manage to find an epimorphism onto a free group of rank k?

Exercise 54.3. We consider the curve C on the surface Σ_3 of genus three that is shown in the figure below.

(a) Show that C represents the trivial element in $\pi_1(\Sigma_3, P)_{\text{ab}}$.
(b) Show that C represents a non-trivial element in $\pi_1(\Sigma_3, P)$.

Exercise 54.4. Let π be the fundamental group of the surface Σ of genus g. Show that π contains a free subgroup of rank 2.
Hint. You could make use of your solution to Exercise 54.2 or you could show that there exists an embedding $\varphi\colon S^1 \vee S^1 \to \Sigma$ such that $\varphi(S^1 \vee S^1)$ is a retract of Σ. We refer to the figure below for an illustration.



Exercise 54.5. Let K be the Klein bottle. Recall that on page 1222 we showed that $\pi_1(K) \cong \langle x, y \mid yxyx^{-1}\rangle$ and in the Fundamental Group-of-Surfaces Proposition 54.5 we showed that $\pi_1(K) \cong \langle x, y \,|\, x^2y^2\rangle$. Give a purely algebraic proof that the groups $\langle x, y \mid yxyx^{-1}\rangle$ and $\langle x, y \,|\, x^2y^2\rangle$ are isomorphic.

Exercise 54.6.

(a) Let M be an oriented connected m-dimensional smooth manifold and let N be a 1-dimensional submanifold *that is diffeomorphic to* S^1. Let $x_0 \in M \setminus N$. Suppose that $m \geq 4$. Show that the inclusion induced map $\pi_1(M \setminus N, x_0) \to \pi_1(M, x_0)$ is an isomorphism.
Hint. Use the Tubular Neighborhood Theorem **??**.
(b) Show that the conclusion (a) does not hold for $m = 3$, i.e. give an example of a connected 3-dimensional smooth manifold M and a connected 1-dimensional submanifold N such that the inclusion induced map $\pi_1(M \setminus N, x_0) \to \pi_1(M, x_0)$ is not an isomorphism.
Remark. The smooth manifold M in the example does not have to be closed.

Exercise 54.7. Let X be the result of removing the interior of a smoothly embedded disk from a torus. Furthermore let Y be the result of removing the interiors of three disjointly smoothly embedded disks from the sphere S^2.

(a) Show that X and Y are homotopy equivalent.
(b) Show that X and Y are not homeomorphic.

Exercise 54.8. Let $g \in \mathbb{N}$ and let Σ be the surface of genus g minus one open disk. We pick a diffeomorphism $\varphi\colon S^1 \to \partial\Sigma$. Let $\psi\colon S^1 \times \partial\Sigma \to \partial\Sigma \times S^1$ be the diffeomorphism given by $(z,w) \mapsto (\varphi(z), \varphi^{-1}(w))$. We consider the inclusion map

$$\begin{array}{rcl} f\colon (S^1 \times \partial\Sigma) \cup_\psi (\partial\Sigma \times S^1) & \to & \Sigma \times \Sigma \\ [(z,w)] & \mapsto & \begin{cases} (z, \varphi(w)), & \text{if } (z,w) \in S^1 \times \partial\Sigma, \\ (\varphi(z), w), & \text{if } (z,w) \in \partial\Sigma \times S^1. \end{cases} \end{array}$$

Show that the induced map

$$f_*\colon \pi_1((S^1 \times \partial\Sigma) \cup_\varphi (\partial\Sigma \times S^1)) \to \pi_1(\Sigma \times \Sigma)$$

has non-trivial kernel.

Remark. You might want to use the Normal Form Theorem 53.25.

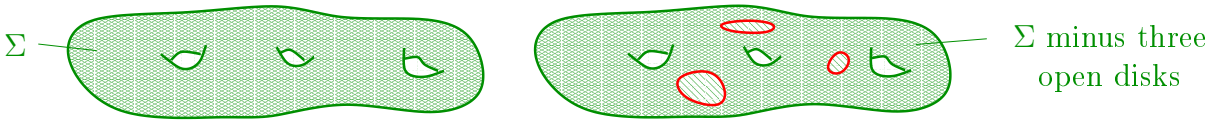
55. The classification of compact 2-dimensional manifolds I

One of the goals of mathematicians is to classify certain objects. For example one goal would be, given a dimension $n \in \mathbb{N}$, to "classify" all compact connected non-empty n-dimensional topological manifolds. But what does "classify" mean? One interpretation would be the following:

(I) Provide a collection $\{X_i\}_{i\in I}$ of compact connected non-empty n-dimensional topological manifolds with the following two properties:
  (a) Any compact connected non-empty n-dimensional topological manifold is homeomorphic to some X_i.
  (b) If $i \neq j$, then X_i and X_j are not homeomorphic.

(II) Furthermore provide an algorithm which determines, given a compact connected n-dimensional topological manifold M, to which X_i it is homeomorphic to.

With obvious modifications the same goal can also be formulated in the smooth setting. For $n = 1$ we have achieved this goal with the Classification Theorems 22.1 and 22.7. In this setting a complete list is given by $\{S^1, [0,1]\}$ and given a compact connected non-empty 1-dimensional topological or smooth manifold it is trivial to determine to which of the two it corresponds.
In this chapter we turn our gaze to the 2-dimensional setting. We will state the classification theorem for topological and smooth manifolds and we will prove (I b) and (II) in the above setting. For the proof of (I a) we will need some patience though, we will only provide it in Chapter 142.



55.1. **Surfaces with boundary.** As mentioned above, one goal of any classification theorem is to provide a "complete" list of objects. We already have a good list of closed surfaces. Now we need to add surfaces with non-empty boundary to our arsenal. We start out with reminding the reader of the following subtle fact.[613]

Proposition 50.7.

(2) Let M be a 2-dimensional smooth manifold. The boundary of M, viewed as a smooth manifold agrees with the boundary of M viewed as a topological manifold.

Now let us move on to the first definition of this chapter,

Definition. Let Σ be a closed connected non-empty 2-dimensional smooth manifold and let $n \in \mathbb{N}_0$. We pick smooth embeddings $\varphi_1, \dots, \varphi_n \colon \overline{B}^2 \to \Sigma$ with disjoint images. We refer to $\Sigma \setminus (\varphi_1(B^2) \cup \dots \cup \varphi_n(B^2))$ as Σ minus n open disks.

The following lemma captures some of the main features of the above definition.

[613] The statement is indeed subtle, for example we will only be able to prove the higher-dimensional analogue in the Topological Manifold Boundary Proposition 75.2 after a thorough study of homology groups.

Lemma 55.1. Let Σ be a closed connected non-empty 2-dimensional smooth manifold and let $n \in \mathbb{N}_0$.

(1) The topological space Σ minus n open disks is a compact connected topological submanifold of Σ with n boundary components, which are given by the boundaries of the closed disks whose interiors were removed.
(2) Σ minus n open disks is a submanifold of the smooth manifold Σ, in particular it is a smooth manifold in its own right.
(3) The diffeomorphism type of the smooth manifold Σ minus n open disks does not depend on the choice of the disks.

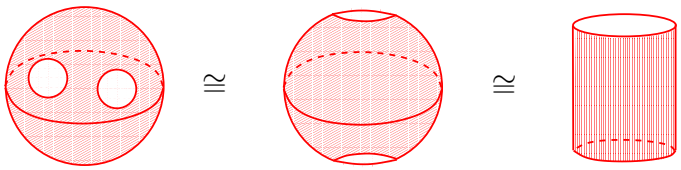
Sketch of proof.

(1),(2) Let $\varphi_1, \dots, \varphi_n \colon \overline{B}^2 \to \Sigma$ be smooth embeddings with disjoint images. Note that we obtain from applying the Codimension-Zero Smooth Embedding Proposition 24.16 (2) iteratively altogether n times that $\Sigma \setminus (\varphi_1(B^2) \cup \dots \cup \varphi_n(B^2))$ is a compact connected submanifold of Σ. In particular we see that it is a smooth and topological manifold in its own right. The fact that the boundary, as a topological manifold, is precisely given by $\varphi_1(S^1), \dots, \varphi_n(S^1)$ follows from Propositions 19.26 and 50.7.
(3) This statement follows easily from the Smooth Ball Embedding Theorem 37.8. ■

This leads us to the following notation:

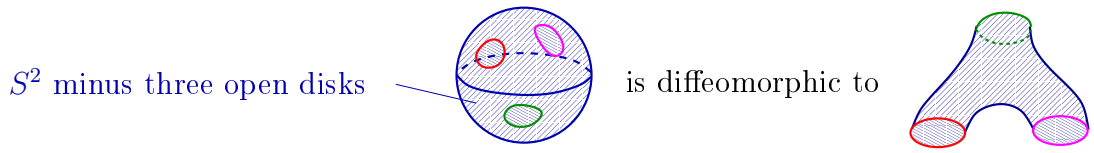
Notation. Given $g, n \in \mathbb{N}_0$ we write

$$\Sigma_{g,n} \quad := \quad \text{the surface of genus } g \text{ minus } n \text{ open disks.}$$



Furthermore for $g \in \mathbb{N}$ and $n \in \mathbb{N}_0$ we write

$$N_{g,n} \quad := \quad \text{the non-orientable surface of genug } g \text{ minus } n \text{ open disks.}$$



Sometimes we refer to g as the genus of $\Sigma_{g,n}$ and also of $N_{g,n}$.

Examples.

(1) The surface $\Sigma_{0,2}$ is the result of removing two open disjoint disks from the 2-sphere. It is pretty elementary to show that the resulting smooth manifold is diffeomorphic to the "cylinder" $[0,1] \times S^1$. We refer to the figure below for an illustration of this statement.

(2) A smooth manifold that is diffeomorphic to S^2 minus three open disks is often called a *pair of pants*. We refer to the figure below for an illustration which hopefully justifies the name. As we will see in Exercise 55.8, pairs of pants can be viewed as a "building block" for almost all compact connected 2-dimensional smooth manifolds.

(3) We saw in the figure on page 571 that the result of removing an open disk from $\mathbb{RP}^2$ is the Möbius band, i.e. $N_{1,1}$ is the Möbius band.

The following lemma shows that the fundamental groups of our new friends are rather dull and uninformative.

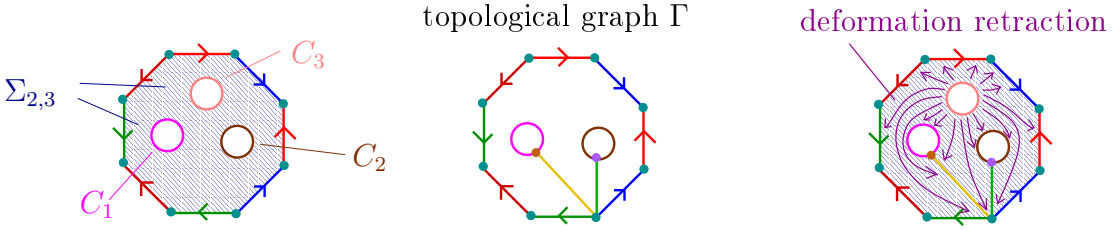
Lemma 55.2.

(1) Given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}$ the surface $\Sigma_{g,n}$ admits a deformation retract to a topological graph of Euler characteristic $2-2g-n$. In particular $\pi_1(\Sigma_{g,n})$ is a free group on $2g+n-1$ generators.

(2) Given $k \in \mathbb{N}$ and $n \in \mathbb{N}$ the surface $N_{k,n}$ admits a deformation retract to a topological graph of Euler characteristic $2-k-n$. In particular $\pi_1(N_{k,n})$ is a free group on $k+n-1$ generators.

Remark. Lemma 55.2 can be viewed as a generalization of the fact, essentially shown in Lemma 52.9, that $\Sigma_{g,1}$ admits a deformation retraction to a wedge Γ of $2g$ circles, which is of course a topological graph of Euler characteristic $1-2g$.

Sketch of proof.



(1) We denote by $C_1, \dots, C_n$ the boundary components of $\Sigma_{g,n}$. Let Γ be the topological space that is given by the wedge of $2g$-circles (which is obtained from identifying as usual the edges of the $4g$-gon pairwise), together with the boundary components $C_1, \dots, C_{n-1}$ and together with edges $e_1, \dots, e_{n-1}$ that connect the wedge point to $C_1, \dots, C_{n-1}$. The deformation retraction from $\Sigma_{g,n}$ to Γ is given by pushing the remaining boundary component C_n "inward". We illustrate this in the figure below. (This is one of the rare occasions where we provide a "proof by picture". It is of course possible to give a completely rigorous proof, but one does not gain anything from doing so.) We equip Γ with the obvious structure of a topological graph which has $n = 1 + (n-1)$ vertices and $2g + 2(n-1)$ edges. Note that $\chi(\Gamma) = 2-2g-n$. Finally we see that

$$\pi_1(\Sigma_{g,n}) \underset{\uparrow}{\cong} \pi_1(\Gamma) \cong \pi_1\left(\begin{array}{c}\text{connected topological graph } \Gamma \\ \text{with } \chi(\Gamma) = 2-2g-n.\end{array}\right) \underset{\uparrow}{\cong} \text{free group on } 2g+n-1 \text{ genera}$$

by the above together with the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3

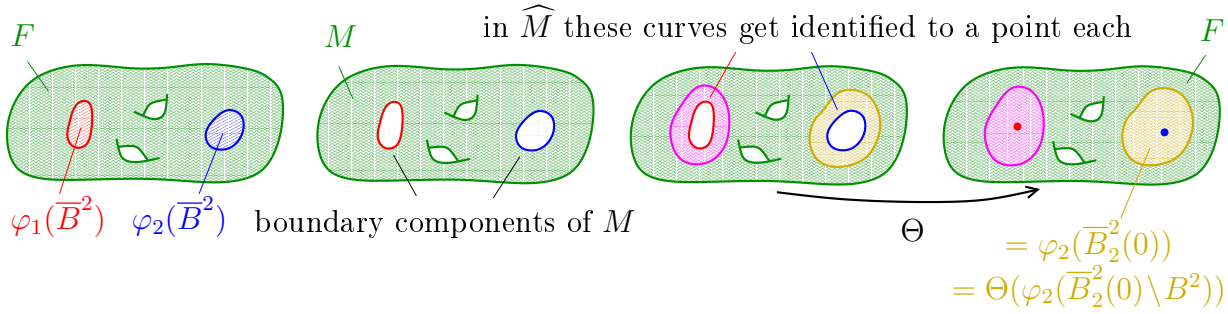
by the Fundamental Grou

(2) The proof of this statement is almost identical to the proof of the first statement.

■

In the following we will see that we can "recover" the closed surfaces Σ_g and N_g from any $\Sigma_{g,n}$ respectively any $N_{g,n}$. The key to doing so is the following definition.

Definition. Let M be a topological manifold. Let "$\sim$" be the equivalence relation on M that is generated by $x \sim y$ whenever x and y lie on the same component of ∂M. We write $\widehat{M} := M/\sim$.



The following lemma shows in particular that $\widehat{\Sigma_{g,n}}$ is homeomorphic to Σ_g and that $\widehat{N_{g,n}}$ is homeomorphic to N_g.

Lemma 55.3. Let F be a closed connected non-empty 2-dimensional smooth manifold and let $n \in \mathbb{N}_0$. If we set M to be F minus n open disks, then $\widehat{M}$ is homeomorphic to F.

Proof. Let $\varphi_1, \dots, \varphi_n \colon \overline{B}^2 \to F$ be smooth embeddings with disjoint images. We need to show that for $M := F \setminus (\varphi_1(B^2) \cup \dots \cup \varphi_n(B^2))$ there exists a homeomorphism $\widehat{M} \to F$. By the Embedding Extension Theorem **??** we can extend the smooth embeddings $\varphi_1, \dots, \varphi_n$ to smooth embeddings $\overline{B}^2_2(0) \to F$ with disjoint images. We consider the following map:[614]

$$\begin{aligned} \Theta \colon \widehat{M} &\to F \\ P &\mapsto \begin{cases} \varphi_i(Q \cdot 2 \cdot (\|Q\| - 1)), & \text{if } P = [\varphi_i(Q)] \text{ for some } i \in \{1, \dots, n\} \text{ and } Q \in \overline{B}^2_2(0) \setminus B^2, \\ P, & \text{otherwise.} \end{cases} \end{aligned}$$

It follows from the Topological-Quotient Proposition 5.15 (1b) and the Smooth Proposition 2.6 (2) that Θ is continuous. Note that by the Compact Image Lemma 2.13 we know that $\widehat{M}$ is compact. Now it follows almost immediately from the Compact-Hausdorff Proposition 2.17 (3) that the given map $\Theta \colon \widehat{M} \to F$ is indeed a homeomorphism. ■

55.2. **The Surface Classification Theorem.** The following theorem achieves Goal (I) that we set out on page 1233.

Theorem 55.4. (Surface Classification Theorem) Every compact connected non-empty 2-dimensional topological manifold is homeomorphic to either

(1) the surface $\Sigma_{g,n}$ for *unique* $g, n \in \mathbb{N}_0$ or

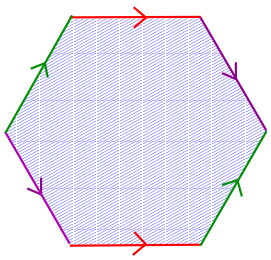
(2) to the surface $N_{k,n}$ for *unique* $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.

Furthermore, if we are given a smooth manifold, then we can upgrade "homeomorphic" to diffeomorphic.

Remark. The surfaces Σ_g, and thus also the surfaces $\Sigma_{g,n}$, come with a canonical orientation and each of these surfaces admits an orientation-reversing self-diffeomorphism given by a reflection. Thus, if we are given a compact *oriented* connected 2-dimensional smooth

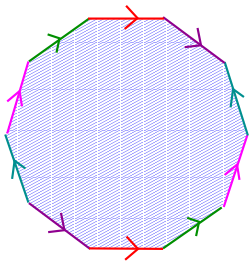
[614] Note that discretely we are using Lemma 55.1 (1) which says that the boundary of M, viewed as a topological manifold, is indeed what we think it should be, namely it is given by $\varphi_1(S^1) \sqcup \dots \sqcup \varphi_n(S^1)$.

manifold, then we can in fact find an *orientation-preserving* diffeomorphism to the corresponding $\Sigma_{g,n}$.



Theorem 55.4 leads us to the following definition.

Definition. Let M be a compact connected non-empty 2-dimensional topological manifold. By the Surface Classification Theorem 55.4 there exists a unique $g \in \mathbb{N}_0$ such that M is homeomorphic to some $\Sigma_{g,n}$ or to some $N_{g,n}$. We refer to g as the genus(M) of M.



At the end of the section we will state a slightly more precise version of the Surface Classification Theorem 55.4 that gives us Goal (II) from page 1233. Before we talk about the proof of the Surface Classification Theorem 55.4 let us discuss a few examples.

Examples.

(1) At least for closed orientable connected 2-dimensional smooth manifolds it is perhaps tempting to dismiss the Surface Classification Theorem 55.4 (1) as "obvious". After all, what other closed orientable connected 2-dimensional smooth manifold could there possibly be? It is thus instructive to consider the figure below. It shows a hexagon and a decagon where *opposite sides* are identified. The quotient spaces are closed orientable 2-dimensional smooth manifolds.[615] To which of the standard surfaces are they diffeomorphic to? We will come back to this question on page 1880.

hexagon with opposite sides identified

dodecagon with opposite sides identified

(2) Let $g \in \mathbb{N}$. We consider the surface Σ_g of genus g. The connected sum $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ contains a Möbius band as a submanifold of codimension zero,[616] hence $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ is non-orientable. It follows from the Surface Classification Theorem 55.4 that $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ is diffeomorphic to $k \cdot \mathbb{R}\mathrm{P}^2$ for some unique $k \in \mathbb{N}$. In Exercise 55.2 we will determine k as a function of g.

The Surface Classification Theorem 55.4 is an immediate consequence of the following three theorems.

Theorem 142.7. Let Σ be a compact connected non-empty 2-dimensional smooth manifold.

(1) If Σ is orientable, then Σ is diffeomorphic to the surface $\Sigma_{g,n}$ for some $g, n \in \mathbb{N}_0$.

[615] Indeed, basically the same proof that showed that the $4g$-gon, with appropriate sides identified, is a closed orientable 2-dimensional smooth manifold also shows that the topological spaces shown in the figure above are closed orientable 2-dimensional smooth manifolds.

[616] This follows from the observation that $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ contains $\mathbb{R}\mathrm{P}^2 \setminus \frac{1}{2}B^2$, which by the figure on page 571 is a Möbius band.

(2) If Σ is non-orientable, then Σ is diffeomorphic to the surface $N_{k,n}$ for some $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.

Theorem 55.5. (Surface-Smooth Structure Existence Theorem) Every compact 2-dimensional topological manifold admits a smooth structure.

Theorem 55.6. (Surfaces-Non Homeomorphic Theorem) The topological spaces $\Sigma_{g,m}$ and $N_{h,n}$ are pairwise non-homeomorphic.[617]

We now turn to the discussion of the proofs of the three theorems.

Proof of the Diffeomorphism-to-Standard Surfaces Theorem 142.7. We provide the proof of the Diffeomorphism-to-Standard Surfaces Theorem 142.7 in Chapter 142. Actually the proof is not as advanced as it may sound. The only ingredient one needs is the notion and existence of a handle decomposition which are given in Chapter 138. We will also sketch an alternative approach to proving the Diffeomorphism-to-Standard Surfaces Theorem 142.7 in Exercise **??**. Also note that there are several other approaches to proving the Diffeomorphism-to-Standard Surfaces Theorem 142.7. For example [**Mata2002**, Chapter 5.2] and [**Hirs1976**, Chapter 9.3] give a proof using "Morse theory".[618] ■

Proof of the Surface-Smooth Structure Existence Theorem 55.5. Let M be a compact 2-dimensional topological manifold. There are two approaches to showing that M admits a smooth structure.

(1) In 1922 Tibor Radó [**Rad1926**] showed that M is homeomorphic to a finite 2-dimensional simplicial complex. Alternative proofs are given in [**Moi1977**, p. 60], [**DM1968**, Corollary 1], [**Tn1992**, Theorem 4.1], [**MTh2001**, Theorem 3.1.1], [**AS1960**, p. 107] and [**GX2013**, Appendix E]. A sketch of the proof is provided in [**Lee2000**, Theorem 5.12].[619]

We will give the definition of a simplicial complex on page 1994. For the purpose of this proof it suffices to know that this means that M is homeomorphic to a topological space that is obtained from gluing finitely many triangles linearly along their sides.

Recall that in Proposition 19.18 we showed that the surface $E_{2g}/\sim$ of genus g admits a smooth structure. The proof can be modified without too many problems to show that any compact 2-dimensional topological manifold that admits a simplicial structure, also admits a smooth structure.

(2) In [**Hat2013**, Theorem A] a direct proof is given for the fact that M admits a smooth structure. Note that this approach does not rely on the Schönflies Theorem 82.4. ■

Since we did not really prove the first two theorems we should at least provide full details for the third theorem. The idea is to find a complete set of invariants to distinguish the $\Sigma_{g,m}$ and $N_{h,n}$ pairwise. The first invariant we want to use is of course the (abelianization) of

[617] In the Surfaces-Non Diffeomorphic Corollary 45.21 we showed the weaker statement that the surfaces Σ_g are pairwise non-diffeomorphic.

[618] We will provide an introduction to Morse Theory in Chapter 138 but we will not discuss how Morse theory can be used directly to prove the Diffeomorphism-to-Standard Surfaces Theorem 142.7. We will only use Morse theory indirectly, since it allows us to study smooth manifolds via handle decompositions, which is the key to our proof of the Diffeomorphism-to-Standard Surfaces Theorem 142.7.

[619] The key ingredient to the proof is the Schönflies Theorem 82.4 which we will formulate later, but which we will not prove.

the fundamental group. But since this invariant is not enough we have to look for further invariants. One idea would be to use the number of boundary components. But as we saw in the figure on page 1189, even this extra information is not enough. To resolve this conundrum let us recall the following notation from page 1236.

Notation. Let M be a topological manifold. Let "$\sim$" be the equivalence relation on M that is generated by $x \sim y$ whenever x and y lie on the same component of ∂M. We write $\widehat{M} := M/\sim$.

The following proposition contains all invariants that we will need.

Proposition 55.7. For $g \in \mathbb{N}_0$ and $k \in \mathbb{N}$ we have the following table of invariants:

X	Σ_g	$\Sigma_{g,m}$ with $n \geq 1$	N_k	$N_{k,n}$ with $n \geq 1$
isomorphism type of $\pi_1(X)_{\text{ab}}$	$\mathbb{Z}^{2g}$	$\mathbb{Z}^{2g+m-1}$	$\mathbb{Z}^{k-1} \oplus \mathbb{Z}_2$	$\mathbb{Z}^{k+n-1}$
number of boundary components	0	n	0	n
isomorphism type of $\pi_1(\widehat{X})_{\text{ab}}$	$\mathbb{Z}^{2g}$	$\mathbb{Z}^{2g}$	$\mathbb{Z}^{k-1} \oplus \mathbb{Z}_2$	$\mathbb{Z}^{k-1} \oplus \mathbb{Z}_2$.

Proof. The proposition is an immediate consequence of Propositions 54.5 and 54.9, together with Lemmas 55.1, 55.2 and 55.3. ■

Now we can prove the Surfaces-Non Homeomorphic Theorem 55.6.

Proof of the Surfaces-Non Homeomorphic Theorem 55.6. It follows immediately from Proposition 55.7 that the $\Sigma_{g,m}$ and $N_{h,n}$ are pairwise non-homeomorphic. For completeness we point out that in Exercise 80.15 we will use (relative) homology groups to give an alternative proof of the Surfaces-Non Homeomorphic Theorem 55.6. ■

Proposition 55.7 also gives us a practical way to determine whether two surfaces are homeomorphic respectively diffeomorphic. This proposition also gives a hopefully satisfying answer to Goal (II) from page 1233.

Proposition 55.8. Let M and N be two compact connected non-empty 2-dimensional topological (respectively smooth) manifolds. The following are equivalent:

(1) M and N are homeomorphic (respectively diffeomorphic),
(2) (a) $\pi_1(M)_{\text{ab}} \cong \pi_1(N)_{\text{ab}}$,
(b) M and N have the same number of boundary components,
(c) $\pi_1(\widehat{M})_{\text{ab}} \cong \pi_1(\widehat{N})_{\text{ab}}$.
In the smooth setting we can replace (c) by
(c') M and N have the same orientability.

Remark.

(1) Only much later, in the Smooth-Topological Orientation Proposition 105.11, will we see that homeomorphisms between smooth manifolds preserve orientability. If we factor this proposition in, then we can replace (c) by (c') also in the topological setting.
(2) In Proposition 64.17 we will see that the fundamental group of the surface Σ_g is not isomorphic to the free group on $2g$ generators. Once we know this fact, one can replace (a) and (b) by $\pi_1(M) \cong \pi_1(N)$.

Proof. In the topological setting this proposition follows immediately from Proposition 55.7 and the Surface Classification Theorem 55.4. In the smooth setting the proposition follows from the above, together with the fact that on page 686 we showed that the $\Sigma_{g,m}$ are orientable and that in the Surface Non-Orientability Lemma 25.20 we showed that the $N_{k,n}$ are non-orientable. ■

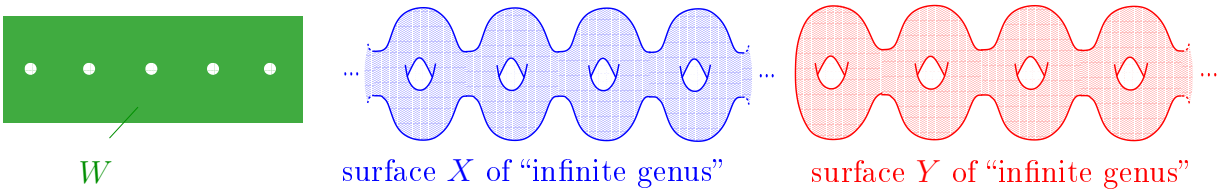
We conclude this discussion of the classification theorem with a long remark on various other approaches to giving the topological classification of 2-dimensional topological manifolds.

Remark. The Surface Classification Theorem 55.4 says in particular that every compact connected non-empty 2-dimensional topological (respectively smooth) manifold is homeomorphic (respectively diffeomorphic) to one of the $\Sigma_{g,n}$ or one of the $N_{k,n}$. Basically all proofs in the literature that deal with the purely topological setting use the fact, mentioned on page 1238, that a 2-dimensional topological manifold admits a simplicial structure. The idea then is to modify the simplicial structure to turn it into a simplicial structure of one of $\Sigma_{g,n}$ or $N_{k,m}$. The traditional account of this proof is given in [**ST1934, ST1980**] or alternatively in [**Mass1991**, Theorem 5.1]. A variation on this proof, which is usually referred to as Conway's Zip Proof, is outlined in [**FW1999, Wild2010**], with full details given in [**Gle**] and [**SchubJ2017**]. Other proofs are given in [**Tn1992**], [**Meie**] and [**AKM2022**]. There is also a proof due to Eric Zeeman, see [**Zee1966, Put2**]. The proof given in [**Arm1988**, Chapter 7] is somewhat different, its basic idea is related to the approach taken in Exercise **??**. Finally we point to [**GX2013**] for a book that is completely dedicated to the proof of the Surface Classification Theorem 55.4 in the topological setting.

By now we might have the impression that we have a solid understanding of surfaces. The following question provides a good test for our true understanding.

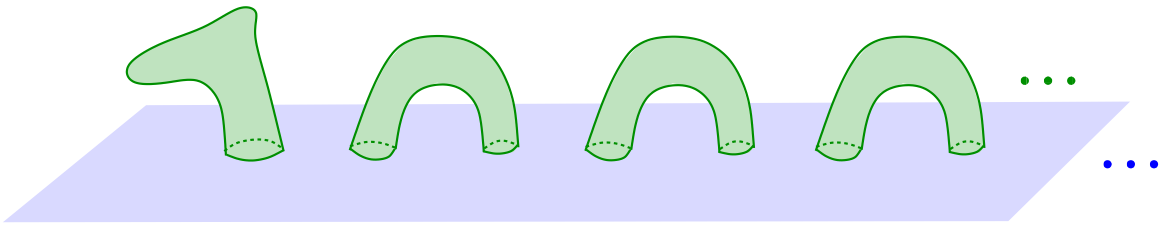
Question 55.9. Let M be the surface of genus $g \in \mathbb{N}_0$ and let $p\colon \widetilde{M} \to M$ be a covering of finite degree d such that $\widetilde{M}$ itself is connected. By the Manifold Covering Proposition 49.2 and Lemma 48.3 we know that $\widetilde{M}$ is a closed orientable connected 2-dimensional smooth manifold. Can we determine the genus of $\widetilde{M}$ in terms of g and d?

We will answer this question later on in the Subgroups-of-Surface Groups Proposition 64.6. It is worth trying to come up with an answer with our current knowledge.



55.3. **Non-compact 2-dimensional smooth manifolds.** Just for kicks we also want to consider *non-compact* 2-dimensional smooth manifolds. A short moment's thought there is a plethora of examples:

(1) Given any connected 2-dimensional smooth manifold Σ and given any non-empty closed discrete subset $A \subset \Sigma$ one can easily show that the complement $\Sigma \setminus A$ is in fact a non-compact connected 2-dimensional smooth manifold. For example, this shows that $W = \mathbb{R}^2 \setminus \{(n,0) \,|\, n \in \mathbb{Z}\}$ is a non-compact connected 2-dimensional smooth manifold.



(2) In the figure below we show two non-compact 2-dimensional smooth manifolds X and Y for which the name "infinite genus" seems appropriate.

In Exercises 55.14 and Exercise 55.15 we will show, with some effort, that the non-compact 2-dimensional smooth manifolds W, X and Y are pairwise not diffeomorphic. This already shows that the classification of non-compact connected 2-dimensional smooth manifolds

can get a little tricky. In fact the classification of non-compact orientable connected 2-dimensional smooth manifolds without boundary was first given by Ian Richards [**Ric1963**] in 1963, building on earlier work of Béla Kerékjártó [**Kere1923**] from 1923. In [**PM2007**] this result was extended to the case of 2-dimensional smooth manifolds with non-empty boundary.

Remark. As an aside we point out that the surface Y of infinite genus shown in the figure above is sometimes called the *Loch Ness monster*. The reason is shown in the figure below: the visible part of an infinite Loch Ness monster, together with the surface of the infinite Loch Ness form a 2-dimensional smooth manifold that is diffeomorphic to Y. More information on the mathematical Loch Ness monster and an explicit rigorous construction are given in [**ARM2017**].

55.4. **Retractions onto boundary components of 2-dimensional smooth manifolds.** In this section we will deal with the following question: for which 2-dimensional smooth manifolds is a given boundary component a retract? This discussion is useful but not essential and one can safely skip this section.

Without further apologies let us recall the following definition from page 1061.

Definition. Let X be a topological space. We say that a subset A of X is a retract of X if there exists a retraction $r\colon X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

For the reader's convenience we also recall the statement of Lemma 47.16.

Lemma 47.16. The circle S^1 is not a retract of $\overline{B}^2$.

We quickly recall the proof of Lemma 47.16.

Proof. We denote by $i\colon S^1 \to \overline{B}^2$ the inclusion map. Suppose there exists a retraction $r\colon \overline{B}^2 \to S^1$, i.e. a map with $r \circ i = \mathrm{id}_{S^1}$. We obtain the commutative diagram

$$\begin{array}{ccc} & \overline{B}^2 & \\ {\scriptstyle i}\nearrow & & \searrow{\scriptstyle r} \\ S^1 & \xrightarrow[r\circ i = \mathrm{id}_{S^1}]{} & S^1 \end{array}$$

which induces the commutative diagram

$$\begin{array}{ccccc} & & \underbrace{\pi_1(\overline{B}^2, 1)}_{=0} & & \\ & {\scriptstyle i_*}\nearrow & & \searrow{\scriptstyle r_*} & \\ \underbrace{\pi_1(S^1, 1)}_{\cong \mathbb{Z}} & & \xrightarrow[(r\circ i)_* = (\mathrm{id}_{S^1})_*]{} & & \underbrace{\pi_1(S^1, 1)}_{\cong \mathbb{Z}}. \end{array}$$

But a commutative diagram as given on the right-hand side cannot exist since an isomorphism of a non-trivial group cannot factor through the trivial group. ■

In light of Lemma 47.16 the following question arises:

Question 55.10. Let Σ be a 2-dimensional smooth manifold and let C be a boundary component of Σ. Is C a retract of Σ?

By the Surface Classification Theorem 55.4 it suffices to address Question 55.10 for the smooth manifolds $\Sigma_{g,m}$ and $N_{h,n}$. For notational convenience we will work throughout with $\Sigma = \Sigma_{g,m}$. We will deal with $\Sigma = N_{h,n}$ in Exercise 55.13.

So let us consider $\Sigma = \Sigma_{g,n}$. Lemma 47.16 says that the answer to Question 55.10 is no if $g = 0$ and $n = 1$. The proof of Lemma 47.16 suggests that if we want to answer Question 55.10, then given a boundary component C of $\Sigma_{g,n}$ we should try to understand the inclusion induced map $\pi_1(C) \to \pi_1(\Sigma_{g,n})$. Of course by Lemma 55.2 we know that $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators. But back then we mostly cared about the isomorphism type of $\pi_1(\Sigma_{g,n})$ and we did not worry about the relationship of $\Sigma_{g,n}$ and its boundary components.

The following lemma gives a new description of $\pi_1(\Sigma_{g,n})$. This description is more complicated in the sense that it is not totally immediate that $\pi_1(\Sigma_{g,n})$ is a free group. On the other hand it makes it clearer how the boundary components of $\Sigma_{g,n}$ interact with $\Sigma_{g,n}$.

Lemma 55.11. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. We denote the boundary components of $\Sigma_{g,n}$ by $C_1, \dots, C_n$. The following statements hold:

(1) Let $* \in \Sigma_{g,n}$ be the standard base point given by the "vertex" of $E_{2g}/\sim$. We pick an orientation for $\Sigma_{g,n}$. There exists a presentation

$$\pi_1(\Sigma_{g,n}, *) \;=\; \langle x_1, y_1, \dots, x_g, y_g, z_1, \dots, z_n \mid [x_1, y_1] \cdot \dots \cdot [x_g, y_g] \cdot z_1 \cdot \dots \cdot z_n \rangle$$

with the following properties:

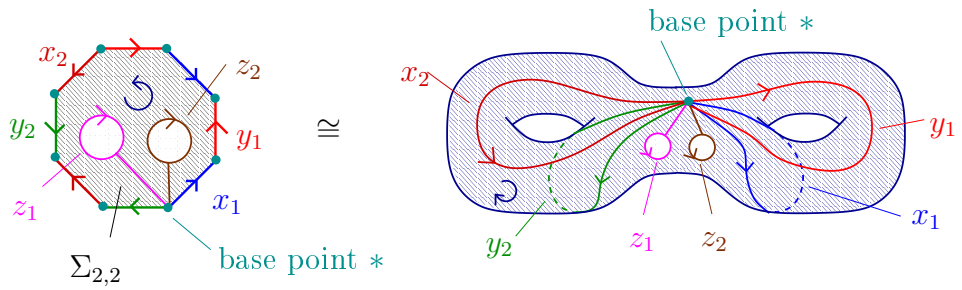
(a) The elements $x_1, y_1, \dots, x_g, y_g$ are represented by the edges of the $2g$-gon in the "usual way".

(b) For any $i \in \{1, \dots, n\}$ the element z_i is represented by a curve of the form $\alpha * \gamma * \overline{\alpha}$ where α is a path from $*$ to a point on C_i and γ is a path that goes once around C_i in an orientation-preserving way.[620]

We refer to the figure below for an illustration.

(2) For every $i \in \{1, \dots, n\}$ the obvious map

$$\underbrace{\langle x_1, y_1, .., x_g, y_g, z_1, .., \widehat{z_i}, .., z_n \rangle}_{\text{free group}} \to \langle x_1, y_1, .., x_g, y_g, z_1, .., z_n \mid \underbrace{[x_1, y_1] \dots [x_g, y_g] \cdot z_1 .. z_n}_{\text{relation}} \rangle$$



is an isomorphism. The inverse is induced by the obvious assignments together with

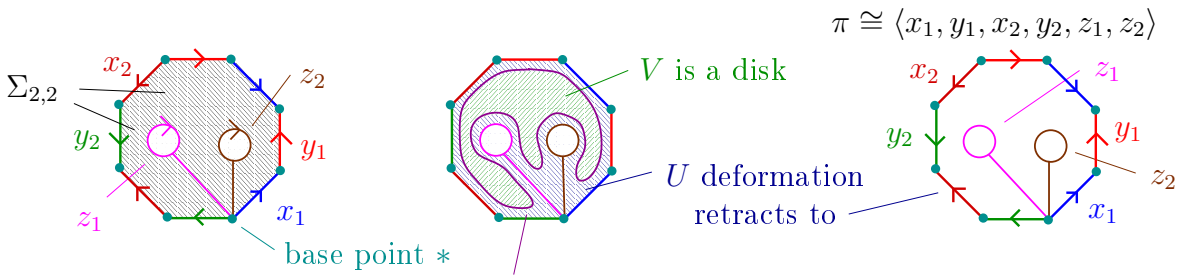
$$z_i \;\mapsto\; {z_{i-1}}^{-1} \cdot \dots \cdot {z_1}^{-1} \cdot [y_g, x_g] \cdot \dots \cdot [y_1, x_g] \cdot {z_n}^{-1} \cdot \dots {z_{i+1}}^{-1}.$$

In particular $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators.

(3) If $g \geq 1$ or if $n \geq 2$, then for every $i \in \{1, \dots, n\}$ the inclusion induced map $\pi_1(C_i) \to \pi_1(\Sigma_{g,n})$ is a monomorphism.

[620] Since we picked an orientation for $\Sigma_{g,n}$ each boundary component also inherits an orientation.

Sketch of the proof. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$.



(1) First note that by Proposition 36.4 we can without loss of generality assume that the base point corresponds to any of the vertices of the $4g$-gon as shown in the figure below. The following argument is very similar to the argument on the pages 1221 and 1224 and it relies heavily on the notation from the figure below. We have

Seifert–van Kampen Theorem 54.1 Amalgamated Product Lemma 53.22

$$\pi_1(\Sigma_{g,n}) \overset{\downarrow}{=} \pi_1(U) *_{\pi_1(U\cap V)} \underbrace{\pi_1(V)}_{=\{e\}} \overset{\downarrow}{\cong} \pi_1(U)/\langle\langle \pi_1(U\cap V)\rangle\rangle$$

$$\overset{\uparrow}{=} \langle x_1, y_1, \dots, x_g, y_g, z_1, \dots, z_n\rangle / \langle\langle [x_1,y_1]\cdot\dots\cdot[x_g,y_g]\cdot z_1\cdot\dots\cdot z_n\rangle\rangle.$$

followings from the deformation retraction shown in the figure below together with the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2)

(2) It follows immediately from the discussion on page 1196 that for any $i \in \{1,\dots,n\}$ the obvious map

$$\langle x_1, y_1, .., x_g, y_g, z_1, .., \widehat{z_i}, .., z_n\rangle \to \langle x_1, y_1, .., x_g, y_g, z_1, .., z_n \mid [x_1,y_1]\dots[x_g,y_g]\cdot z_1..z_n\rangle$$

is an isomorphism. The map that we give in the inverse direction is evidently a converse.

(3) Now suppose that $g \geq 1$ or that $n \geq 2$. Let $i \in \{1,\dots,n\}$. The image of $\pi_1(C_i)$ in $\pi_1(\Sigma_{g,n})$ is the subgroup generated by z_i. It suffices to show that z_i is an element of infinite order in $\pi_1(\Sigma_{g,n})$. We apply (2) to i. We obtain an isomorphism

$$\begin{aligned} \pi_1(\Sigma_{g,n}) &\to \langle x_1, y_1, \dots, x_g, y_g, z_1, \dots, \widehat{z_i}, \dots, z_n\rangle \\ z_i &\mapsto z_{i-1}{}^{-1}\cdot\dots\cdot z_1{}^{-1}\cdot[y_g,x_g]\cdot\dots\cdot[y_1,x_1]\cdot\dots z_n{}^{-1}\cdot\dots\cdot z_{i+1}{}^{-1}. \end{aligned}$$

Since $g \geq 1$ or $n \geq 2$ we see that the element on the right-hand side is represented by a non-empty reduced word. Thus by definition it represents a non-trivial element

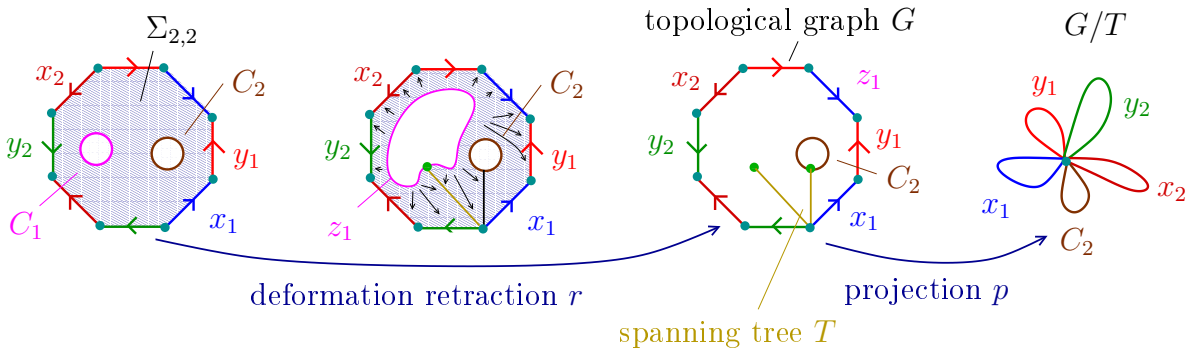
in a free group. By Lemma 51.14 we know that every non-trivial element of a free group has infinite order. Thus we have shown that z_i is indeed an element of infinite order of $\pi_1(\Sigma_{g,n})$. ■

Finally the following technical lemma can be viewed as a refinement of Lemma 55.2 (1).

Lemma 55.12. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$.

(1) We denote the boundary components of $\Sigma_{g,n}$ by $C_1, \dots, C_n$. Given any $i \in \{1, \dots, n\}$ there exists a topological graph $G \subset \Sigma_{g,n}$ which contains all C_j with $i \neq j$ and which contains a point on C_j, a deformation retraction $r\colon \Sigma_{g,n} \to G$, a spanning tree $T \subset G$ and a homeomorphism[621]

$$\Theta\colon G/T \;\to\; C_1 \vee \dots \vee \widehat{C_i} \vee \dots \vee C_n \vee \underbrace{S^1 \vee \dots \vee S^1}_{2g \text{ copies}}$$



such that the following diagram commutes:

$$\begin{array}{ccccc} & & C_j & \longrightarrow & C_1 \vee \dots \vee \widehat{C_i} \vee \dots \vee C_n \vee S^1 \vee \dots \vee S^1 \\ & \swarrow & \downarrow & & \Theta \downarrow \cong \\ \Sigma_{g,n} & \xrightarrow{r} & G & \xrightarrow{\quad p \quad} & G/T. \end{array}$$

Note that $(p \circ r)_*\colon \pi_1(\Sigma_{g,n}) \to \pi_1(G/T)$ is an isomorphism by Propositions 50.3 and 50.15 (1).

(2) The fundamental group $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators.

Given $k \in \mathbb{N}$ and $n \in \mathbb{N}$ completely analogous statements also hold for $N_{k,n}$.

Sketch of proof.

(1) In the figure we show that, starting from any boundary component C_i of $\Sigma_{g,n}$, we can push "inward" to obtain a deformation retraction[622][623] to a subset that is a topological graph G that can be described as

$$G \;=\; \big(C_1 \sqcup \dots \sqcup \widehat{C_i} \sqcup \dots \sqcup C_n \sqcup \underbrace{S^1 \vee \dots \vee S^1}_{2g \text{ copies}}\big) \text{ together with a spanning tree } T.$$

[621] Here $\widehat{C_i}$ means that we leave out C_i.

[622] We leave it to others with more time and energy to write down a rigorous argument. One possibility would be to apply several times the deformation retractions that we found in Exercise 15.13.

[623] This argument is evidently closely related to the proof of Lemma 52.9.

The vertical map to the right is the homeomorphism given by the discussion on page 1133. It follows immediately from the construction that the diagram commutes.

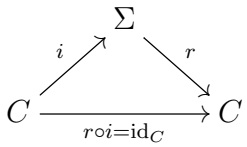
(2) This statement follows from (1) together with the Fundamental Group-Wedge-of-Circles Lemma 52.4. ■

The proof for $N_{k,n}$ is almost identical to the above proof for $\Sigma_{g,n}$. We leave it to the reader to figure out the precise statements and to write down the proof.

The following lemma gives an answer to Question 55.10.

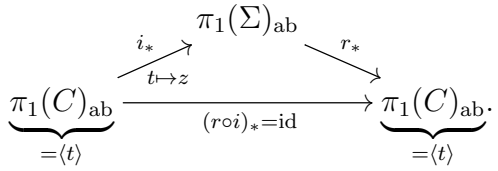
Lemma 55.13. Let $g \in \mathbb{N}_0$.

(1) The unique boundary component of $\Sigma_{g,1}$ is not a retract of $\Sigma_{g,1}$.
(2) For $k \geq 2$ every boundary component of $\Sigma_{g,k}$ is a retract of $\Sigma_{g,k}$.



Proof. Let $g \in \mathbb{N}_0$.

(1) The case $g = 0$ was dealt with in Lemma 47.16. Now we assume that $g \geq 1$. We denote by C the unique boundary component of $\Sigma := \Sigma_{g,1}$. We had just seen in Lemma 55.11 that $\pi_1(C) \to \pi_1(\Sigma)$ is a monomorphism if $g \geq 1$. So we cannot apply the same argument as in Lemma 47.16 where we studied the induced map on the level of fundamental groups. The idea now is to study instead the induced map on the *abelianizations* of the fundamental groups.

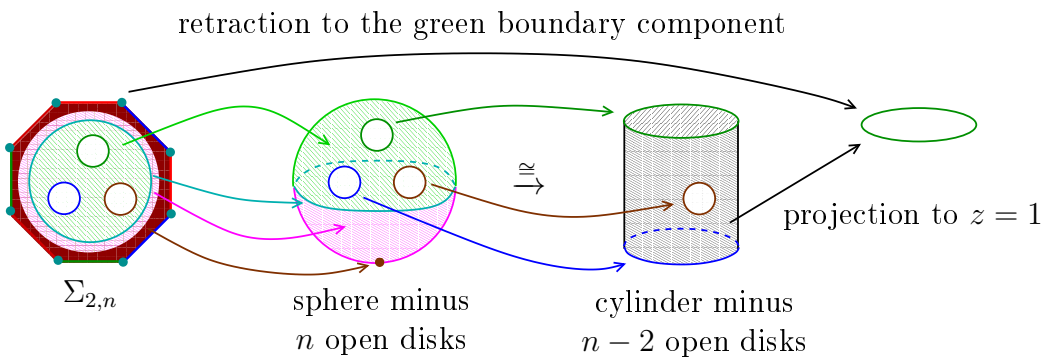


We denote by $i\colon C \to \Sigma$ the inclusion map and we suppose that there exists a retraction $r\colon \Sigma \to C$, i.e. a map with $r \circ i = \mathrm{id}_C$. We write $\pi_1(C) = \langle t \rangle$ and we use the isomorphism from Lemma 55.11 (1) to make the identification

$$\pi_1(\Sigma) \;=\; \langle x_1, y_1, \ldots, x_g, y_g, z \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \cdot z \rangle$$

where z corresponds to t under the inclusion $C = \partial\Sigma \to \Sigma$. We obtain the commutative diagram

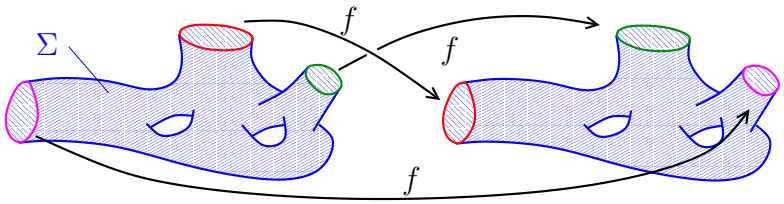
which induces by Proposition 53.20 (6) the commutative diagram



In $\pi_1(\Sigma)$ we have

$$z \;=\; ([x_1, y_1] \cdot \cdots \cdot [x_g, y_g])^{-1} \;\in\; \pi_1(\Sigma).$$

This shows that z lies in the commutator subgroup of $\pi_1(\Sigma)$, i.e. z represents the trivial element in $\pi_1(\Sigma)_{\mathrm{ab}}$. Thus we have shown that the left diagonal map is the zero map. But the bottom horizontal map is an isomorphism of a non-trivial group and the diagram commutes. We have thus obtained a contradiction.

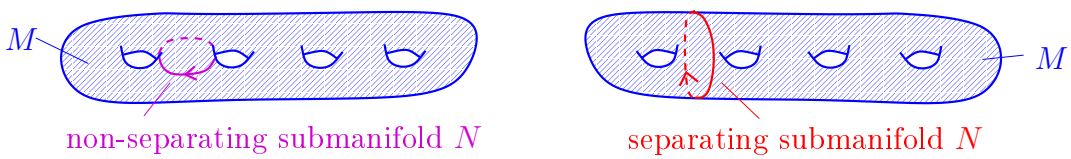


(2) This statement follows immediately from Lemma 55.12 since we can project the wedge of circles onto any circle. Alternatively, a retraction from $\Sigma_{2,n}$ to a boundary component is sketched in the figure below. The general case is treated the same way.[624] ■

[624] The proof is somewhat similar to the proof of Lemma 47.19.

55.5. **Curves on surfaces.** In this section we will use the Surface Classification Theorem 55.4 to draw several hopefully interesting consequences on curves on surfaces. We start out with the following lemma.

Lemma 55.14. (Boundary Curve-Permutation Lemma) Let Σ be a compact connected 2-dimensional smooth manifold. We denote the boundary components of Σ by $C_1, \ldots, C_n$. Given any permutation $\sigma \in S_n$ there exists a diffeomorphism f of Σ with $f(C_i) = C_{\sigma(i)}$, $i = 1, \ldots, n$. Furthermore, if Σ is oriented, then we can choose f to be orientation-preserving.



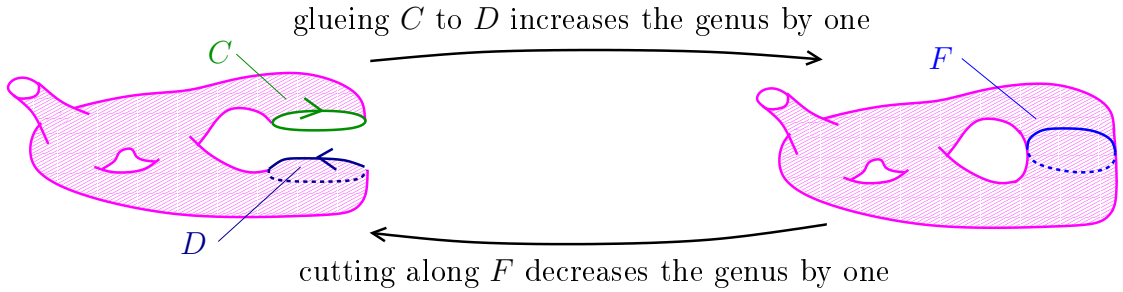
Proof. In the proof we deal with the setting that Σ is orientable. The case that Σ is non-orientable is dealt with in almost the same way. We pick an orientation for Σ and we equip the boundary components $C_1, \ldots, C_n$ with the corresponding orientations. Furthermore we pick orientation-reversing diffeomorphisms $\varphi_1, \ldots, \varphi_n \colon S^1 \to C_i$ and we consider

$$M \;:=\; (\Sigma \sqcup (\overline{B}^2_1 \sqcup \cdots \sqcup \overline{B}^2_n))/\varphi_i(x) \sim x \qquad \text{with } x \in S^1 \text{ and } i \in \{1, \ldots, n\}.$$

It follows from the Codimension-Zero Submanifold Proposition 19.38 that M is a closed oriented connected 2-dimensional smooth manifold with obvious orientation-preserving smooth embeddings $\psi_i \colon \overline{B}^2 \to M$. Now let $\sigma \in S_n$ be a permutation. Note that it follows from the Smooth Ball Embedding Theorem 37.8 that there exists a diffeotopy $F \colon M \times [0,1] \to M$ with $F_0 = \mathrm{id}$ such that for each $i \in \{1, \ldots, n\}$ we have $F_1 \circ \varphi_i = \varphi_{\sigma(i)} \colon \overline{B}^2 \to M$. Note that F_1 is orientation-preserving by the Smooth Isotopy-Orientation Proposition 34.2. The desired diffeomorphism is now given by the restriction of F_1 to Σ. ■

We move on to the following general definition.

Definition. Let M be a smooth manifold and furthermore let $N \subset M$ be a closed submanifold of codimension one. We say N is non-separating if $M \setminus N$ is connected, otherwise we see that N is separating.



Next we recall that on page **??** we introduced the notion of cutting an orientable smooth manifold along a proper codimension-one submanifold. In Proposition **??** (4) and Proposition **??** we saw that this is operation is the inverse of the operation of gluing two boundary components that we introduced in the Gluing-Smooth Manifolds-Proposition **??**. We will not recall the precise definitions but we hope that the figure below will bring back fond memories.

The following lemma explains how gluing and cutting affects surfaces.

Lemma 55.15. (Surface-Gluing-Cutting Lemma) Let Σ be a compact oriented connected 2-dimensional smooth manifold.

(1) Let C and D be two distinct boundary components of Σ. Gluing C to D via an orientation-reversing diffeomorphism increases the genus by one and it decreases the number of boundary components by two.
(2) Let F be a closed non-separating curve on Σ. Cutting along F decreases the genus by one and it increases the number of boundary components by two. (In particular this implies that the genus of Σ is ≥ 1.)

Sketch of proof.

(1) By the Surface Classification Theorem 55.4 we can assume that $\Sigma = \Sigma_{g,n}$ for some $g \in \mathbb{N}_0$ and some $n \in \mathbb{N}_{\geq 2}$. We denote by M the result of gluing the boundary components C and D via an orientation-reversing diffeomorphism. Note that it follows from the Gluing-Smooth Manifolds-Proposition **??** that M is a compact oriented connected 2-dimensional smooth manifold. In particular it has some genus h. Also note that it follows from the Boundary Curve-Permutation Lemma 55.14 that the diffeomorphism type of M does not depend on the choice of the two boundary components C and D.

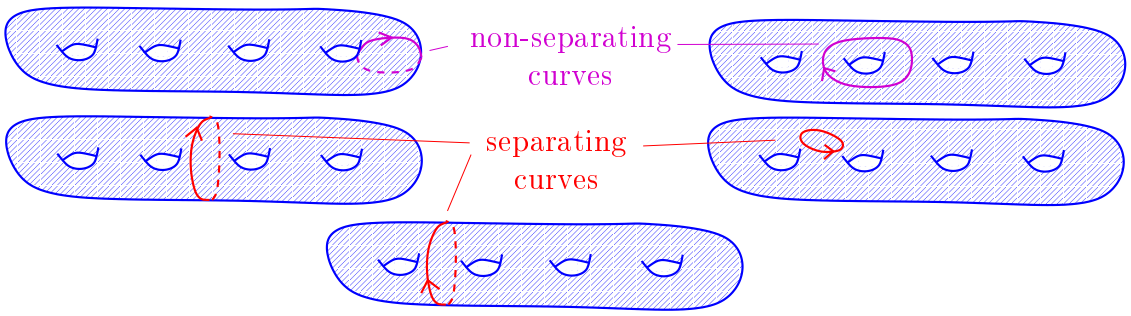
It is now elementary, albeit painful, to show clearly that gluing C to D via an orientation-reversing diffeomorphism increases the genus by one. We will deal with a special case in Exercise 55.12. The general case is not much harder. Finally note that evidently the number of boundary components goes down by two.

For readers who are slightly unhappy about the above proof of the statement that the genus goes up by one we also give an alternative approach. Namely, the genus of M can be read off directly from suitable invariants. For example later on we will

use the HNN-Seifert–van Kampen Theorem 57.3 to calculate $\pi_1(M)$ which, together with Proposition 55.7 implies that $h = g + 1$. Alternatively one can use the Euler characteristic, which we will introduce in Chapter 87, together with Lemmas 87.5 and 87.6 to see once again that $h = g + 1$.

(2) Note that if we cut along a non-separating curve, then the resulting 2-dimensional smooth manifold is again connected. Thus we see that Statement (2) is an immediate consequence of Statement (1) together with Proposition **??**. ■

We move on to the following definition.



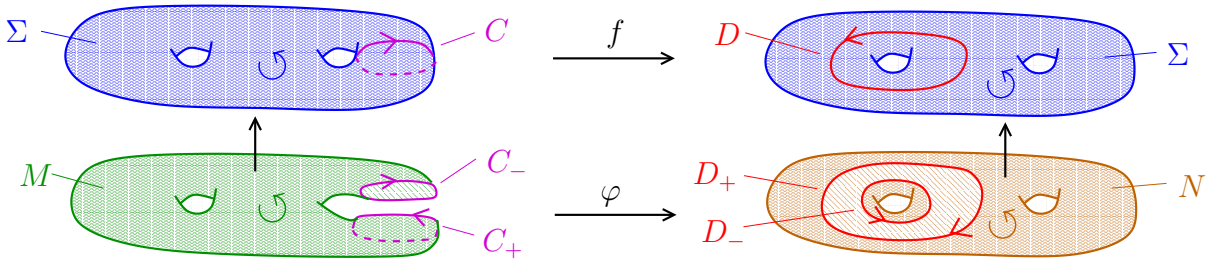
Definition. Let Σ be an oriented 2-dimensional smooth manifold and let C and D be two closed oriented curves in Σ. We say C and D are equivalent if there exists an orientation-preserving self-diffeomorphism f of Σ that restricts to an orientation-preserving diffeomorphism $f\colon C \to D$.

It is clear that if two curves are equivalent, then either both are separating or both are non-separating. Furthermore if they are both separating, then the results of cutting the 2-dimensional smooth manifold along the curves are diffeomorphic. The following theorem gives us the converse to this observation.

Theorem 55.16. (Curves-on-Surfaces-Classification Theorem) Let Σ be a compact oriented connected 2-dimensional smooth manifold and let C and D be two closed oriented curves in $\Sigma \setminus \partial\Sigma$.

(1) If C and D are non-separating, then C and D are equivalent.
(2) Suppose C and D are separating. If Σ cut along C is diffeomorphic to Σ cut along D, then C and D are equivalent.

Example. It follows from the Curves-on-Surfaces-Classification Theorem 55.16 (1) that the two non-separating curves shown in the figure below are actually equivalent. Furthermore it follows easily from the Curves-on-Surfaces-Classification Theorem 55.16 (2) and the future Exercise 87.5 that any separating curve on the surface of genus four is equivalent to one of the separating curves shown in the figure below.

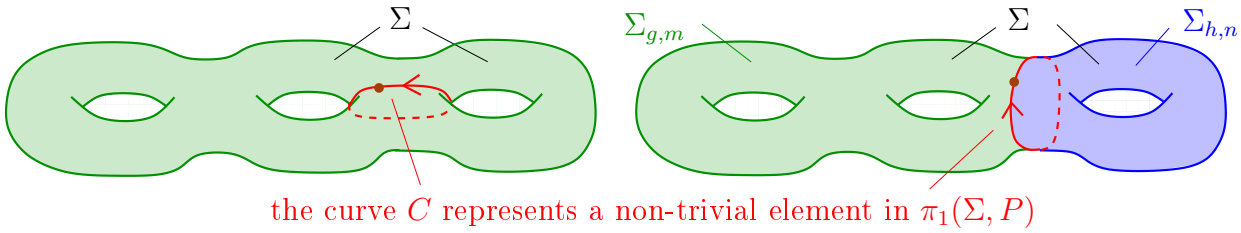


Remark. In Exercise 55.17 we will generalize the Curves-on-Surfaces-Classification Theorem 55.16 to certain pairs of curves.

Sketch of proof. Let Σ be a compact oriented connected 2-dimensional smooth manifold.

(1) Let C and D be two closed oriented non-separating curves on Σ. We denote by M respectively N the smooth manifold obtained from Σ by cutting along C respectively D. We denote by $C_\pm$ and $D_\pm$ the boundary components arising from

C and D. Since C and D are non-separating it follows from the Surface-Gluing-Cutting Lemma 55.15 (2) and the Boundary Curve-Permutation Lemma 55.14 that there exists an orientation-preserving diffeomorphism $\varphi\colon M \to N$ that restricts to orientation-preserving diffeomorphisms $\varphi\colon C_\pm \to D_\pm$. Using Lemma 50.1 and using a collar neighborhood one can arrange that under the obvious identifications $C_- = C_+$ and $D_- = D_+$ the maps $\varphi\colon C_- \to D_-$ and $\varphi\colon C_+ \to D_+$ agree. As in the Gluing-Smooth Manifolds-Proposition **??** (7) we see that $\varphi\colon M \to N$ descends to an orientation-preserving diffeomorphism $\overline{\varphi}\colon M/C_- = C_+ \to N/D_- = D_+$. If we combine this diffeomorphism with the diffeomorphisms $\Sigma \to M/C_- = C_+$ and $\Sigma \to N/D_- = D_+$ from Proposition **??** we obtain the desired diffeomorphism.



(2) The argument is similar to the proof of Statement (1), except that we do not need to appeal to the Surface-Gluing-Cutting Lemma 55.15 (2), instead we can use our hypothesis directly. We leave it to the reader to fill in the details. ■

In the remainder of this section we will state a few consequences of the Curves-on-Surfaces-Classification Theorem 55.16.

Proposition 55.17. Let Σ be a compact orientable connected 2-dimensional smooth manifold and let C be a closed oriented curve on Σ.

(1) If C is non-separating, then C is not null-homotopic.
(2) If C is separating, and if the two components of Σ cut along C are not disks, then C is not null-homotopic.

Proof. Let Σ be a compact 2-dimensional smooth manifold and let C be a closed oriented curve on Σ.

(1) First assume that C is non-separating. By the Surface Classification Theorem 55.4 we can assume that $\Sigma = \Sigma_{g,n}$ for some $g \in \mathbb{N}_0$ and some $n \in \mathbb{N}_0$. Since C is non-separating we know by the Surface-Gluing-Cutting Lemma 55.15 (2) that $g \geq 1$. Next note that by the Curves-on-Surfaces-Classification Theorem 55.16 we only need to show that there exists a single non-separating curve on $\Sigma_{g,n}$ that is not null-homotopic. By Lemma 55.11 we have a presentation

$$\pi_1(\Sigma_{g,n}, *) \;=\; \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \cdot z_1 \cdot \cdots \cdot z_n \rangle$$

where each x_i is represented by a non-separating curve. But the x_i represent non-trivial elements in the abelianization of $\pi_1(\Sigma_{g,n})$, in particular the corresponding curves are not null-homotopic.

(2) Now we suppose that C is separating. We cut Σ along C and we obtain two connected surfaces. By the Surface Classification Theorem 55.4 we can assume that the two surfaces are of the form $\Sigma_{g,m}$ and $\Sigma_{h,n}$. By hypothesis neither surface is a disk, so we have $g > 0$ or $m > 1$ and we have $h > 0$ or $n > 1$. To simplify the notation we now assume that $g = 1$ and $h = 1$ and $m = 2$ and $n = 2$. We perform the following calculation:

$$\begin{array}{l} \text{Seifert–van Kampen Theorem 54.4} \qquad \text{by Lemma 55.11, here } C \text{ corresponds to } c_1 \text{ and to } z_1^{-1} \\ \pi_1(\Sigma) \overset{\downarrow}{\cong} \pi_1(\Sigma_{1,2}) *_{\pi_1(C)} \pi_1(\Sigma_{1,2}) \overset{\downarrow}{=} \langle a,b,c_1,c_2 | [a,b]\cdot c_1\cdot c_2\rangle *_{\pi_1(C)} \langle x,y,z_1,z_2 | [x,y]\cdot z_1\cdot z_2\rangle \\ \qquad = \langle a,b,c_1,c_2,x,y,z_1,z_2 \,|\, [a,b]\cdot c_1\cdot c_2, [x,y]\cdot z_1\cdot z_2, c_1 = z_1^{-1}\rangle \\ \qquad\quad \overset{\uparrow}{} \\ \qquad \text{by Lemma 53.23} \end{array}$$

where the curve C corresponds to $c_1 = z_1^{-1}$. We need to show that c_1 represents a non-trivial element in $\pi_1(\Sigma)$. In our present setting we see that c_1 represents a non-trivial element in the abelianization, but this is *not* the case if $m = 1$. So we need to come up with an alternative argument to show that c_1 is non-trivial. Note that it follows from Lemma 53.13 that there exists a homomorphism

$$\varphi\colon \langle a,b,c_1,c_2,x,y,z_1,z_2 \mid [a,b]\cdot c_1\cdot c_2, [x,y]\cdot z_1\cdot z_2, c_1 = z_1^{-1}\rangle \;\to\; \langle u,v\rangle$$

with[625]

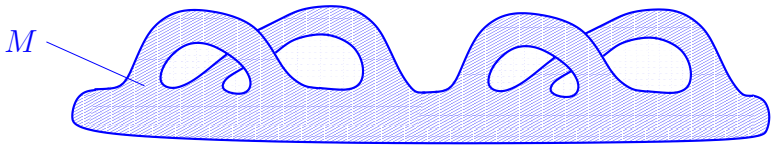
$$a \mapsto u, \quad b \mapsto v, \quad c_1 \mapsto [v,u], \quad c_2 \mapsto e, \quad x \mapsto v, \quad y \mapsto u, \quad z_1 \mapsto [u,v], \quad z_2 \mapsto e.$$

Finally note that $\varphi(c) = [u,v]$ is a non-trivial element of the free group $\langle u,v\rangle$. It follows that C is not null-homotopic. ■

Remark. What is the "right" proof for a statement is often a matter of taste. For example an alternative, arguably more conceptual, proof for Proposition 55.17 (1) can be obtained by the combination of the Surface Classification Theorem 55.4 together with the future HNN-Seifert–van Kampen Theorem 57.3, Lemma 55.11 (3) and the HNN-Extension Monomorphism Proposition 57.2. Similarly an alternative proof for Proposition 55.17 (2) can be obtained by the combination of the Surface Classification Theorem 55.4 with Seifert–van Kampen Theorem 54.4, Lemma 55.11 (3) and the Amalgamated Product-Monomorphism Proposition 53.24.

We conclude this section with the following consequence of Proposition 55.17.

Proposition 55.18. Let Σ be a compact orientable 2-dimensional smooth manifold. Furthermore let $f\colon S^1 \to \Sigma$ be a smooth embedding. If f is null-homotopic, then there exists a smooth embedding $F\colon \overline{B}^2 \to \Sigma$ with $F|_{S^1} = f$.



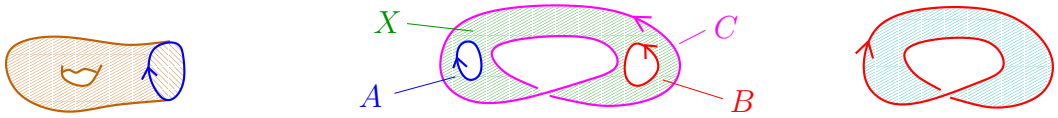
Proof. Let $f\colon S^1 \to \Sigma$ be a smooth embedding that is null-homotopic. By Proposition 55.17 (1) we know that $f(S^1)$ is separating. Let A and B be the two components of Σ cut along $f(S^1)$. By Proposition 55.17 (2) we know that at least one of A and B is

[625] Recall that $[s,t]$ denotes the commutator of s and t, i.e. we have $[s,t] = sts^{-1}t^{-1}$. The verification that the relations are indeed satisfied relies on the trivial but useful observation that $[s,t]^{-1} = [t,s]$.

diffeomorphic to a disk. Let us assume that A is diffeomorphic to $\overline{B}^2$. It follows easily from Lemma 50.1 (3), see also the Diffeomorphisms-of-S^1-Extension Corollary 34.6, that there exists such a diffeomorphism $F\colon \overline{B}^2 \to A$ with $F|_{S^1} = f$. ■

Exercises for Chapter 55.

Exercise 55.1. Determine the genus of the surface M shown in the figure below.

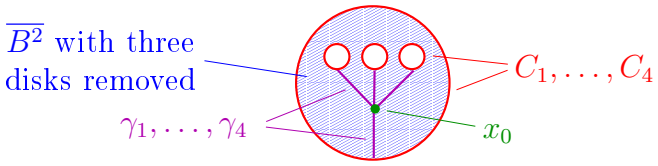


Exercise 55.2. Let $g \in \mathbb{N}$. By the Surface Classification Theorem 55.4 we know that $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ is diffeomorphic to $k \cdot \mathbb{R}\mathrm{P}^2$ for some unique $k \in \mathbb{N}$. Determine k as a function of g.

Exercise 55.3. Let X be the Möbius band minus two disks. We denote by A, B, C the three boundary components of X. We glue a torus minus one open disk and a Möbius band to the boundary components of X. By the Gluing-Smooth Manifolds-Proposition **??** we obtain a compact 2-dimensional smooth manifold.

(a) Do the resulting diffeomorphism types depend on the gluing?
(b) How do the resulting smooth manifolds fit into the classification scheme of the Surface Classification Theorem 55.4?

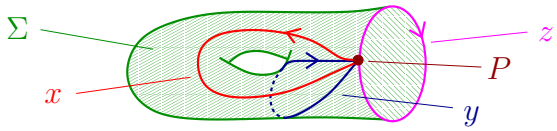
We refer to the figure below for an illustration.



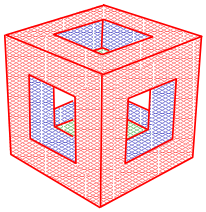
torus minus one disk | Möbius band minus two disks | Möbius band

Exercise 55.4. Recall that in the figure on page 571 we saw that $N_{1,1}$ is a Möbius band. In particular we can view $N_{0,1}$ as a submanifold of $\mathbb{R}^3$.

(a) Is $N_{2,1}$ diffeomorphic to a submanifold of $\mathbb{R}^3$?
(b) Show that $N_{3,1}$ is diffeomorphic to a submanifold of $\mathbb{R}^3$.
(c) For which $k \in \mathbb{N}$ is $N_{k,1}$ diffeomorphic to a submanifold of $\mathbb{R}^3$?



Exercise 55.5. Let F be the sphere minus k open disks. (Alternatively, let F be the disk $\overline{B}^2$ minus $k-1$ open disks.) We denote by $C_1, \dots, C_k$ the boundary components of F. We pick a base point $x_0 \in F$. Furthermore for each $i \in \{1, \dots, k\}$ we pick a path γ_i from a point on C_i to x_0. Finally let $\Gamma \subsetneq \pi_1(F, x_0)$ be a proper normal subgroup. Show that there exists an $i \in \{1, \dots, k\}$ such that C_i, viewed as an element in $\pi_1(F, x_0)$ via the path γ_i, does not lie in Γ.
Hint. You might want to start out with your preferred base point x_0 and your preferred paths $\gamma_1, \dots, \gamma_k$, e.g. as shown in the figure below.



Exercise 55.6. Let Σ be the torus minus one disk. We denote by $P \in \partial\Sigma$ a base point. Furthermore let x, y, z be the curves shown in the figure below. We denote by x, y, z also the elements in $\pi_1(\Sigma, P)$ represented by these curves.

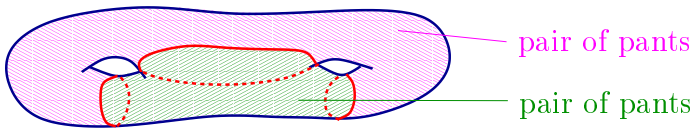
(a) Convince yourself of the fact that $\pi_1(\Sigma, P) = \langle x, y, z \,|\, [x, y] = z \rangle$.
Remark. This statement is closely related to the statement of Lemma 55.11, but it takes some effort to get the orientations of the curves right.

(b) Show that $z \in \pi_1(\Sigma, P)$ is not a proper power, i.e. show that there is no $w \in \pi_1(\Sigma, P)$ such that $z = w^d$ for some $d \in \mathbb{N}_{\geq 2}$.

Exercise 55.7. What is the genus of the surface shown in the figure below.

Exercise 55.8. We say a 2-dimensional smooth manifold M admits a *pair of pants decomposition* if there exist submanifolds $P_1, \dots, P_k$ such that each P_i is a pair of pants and such that for each $i \neq j$ the intersection $P_i \cap P_j$ is a (possibly empty) union of boundary components of P_i and also of P_j.

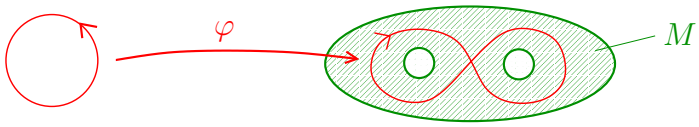
(a) Determine all $g, n \in \mathbb{N}_0$ such that $\Sigma_{g,n}$ admits a pair of pants decomposition.



(b) Determine all $g \in \mathbb{N}$ and $n \in \mathbb{N}_0$ for which $N_{k,n}$ admits a pair of pants decomposition.

Exercise 55.9. Let Σ be a compact connected 2-dimensional smooth manifold and let C and D be two closed oriented non-separating curves in $\Sigma \setminus \partial\Sigma$. In the Curves-on-Surfaces-Classification Theorem 55.16 we showed that if Σ is orientable, then there exists a self-diffeomorphism φ of Σ with $\varphi(C) = D$.

(a) Show that this conclusion does not necessarily hold if we drop the hypothesis that Σ is orientable.

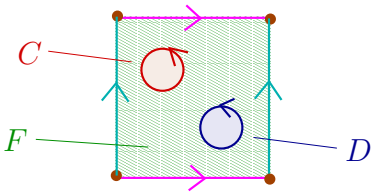


(b) Where in the proof of the Curves-on-Surfaces-Classification Theorem 55.16 did we really make use of the hypothesis that Σ is orientable?

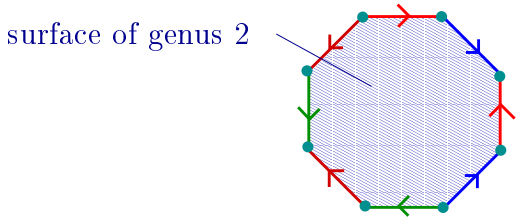
Exercise 55.10. We consider the 2-dimensional smooth manifold M together with the map $\varphi\colon S^1 \to M$ that is shown in the figure below. Show that φ is not homotopic to a

smooth embedding.

Remark. At this stage it is a challenging, but by now means impossible, task to provide a completely rigorous proof.



Exercise 55.11.

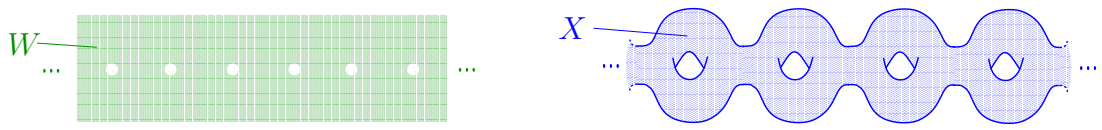


(a) Let $k \in \mathbb{N}$. By Proposition 49.4 we know that the non-orientable surface N_k admits an essentially unique 2-fold covering $\Sigma \to N_k$ that is orientable. What is the genus of Σ?
Hint. First deal with the cases $N_1 \cong \mathbb{R}\mathrm{P}^2$ and $N_2 \cong \mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$. Given $k \in \mathbb{N}_{\geq 2}$ you can write N_k as the connected sum of an orientable smooth manifold with $\mathbb{R}\mathrm{P}^2$ or with $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$.

(b) Let $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$. By Proposition 49.4 we now know that the non-orientable surface $N_{k,m}$ admits an essentially unique 2-fold covering $\Sigma \to N_{k,m}$ that is orientable. What is the genus of Σ and what is the number of boundary components of Σ?

Hint. In Exercise 87.2 we will give a different, perhaps less ad hoc approach to dealing with these two questions.

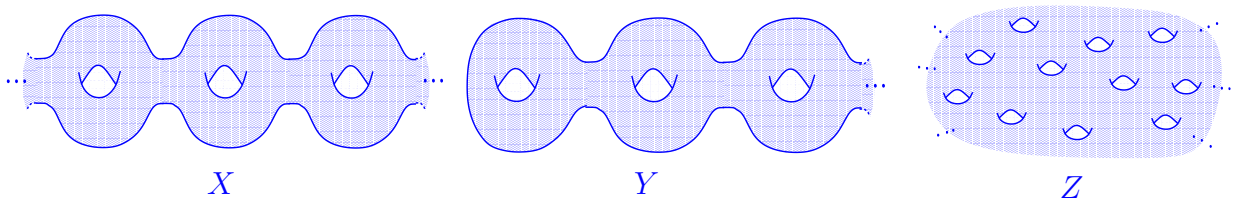
Exercise 55.12. Let F be the torus minus two open disks. We pick an orientation-reversing diffeomorphism $\varphi\colon C \to D$ between the two boundary components. Show that $F/c \sim \varphi(c)$ is diffeomorphic to the surface of genus two.



Exercise 55.13. For which values of $g \in \mathbb{N}$ and $n \in \mathbb{N}$ is every boundary component of $N_{g,n}$ a retract of $N_{g,n}$?

Exercise 55.14. Let $W = \mathbb{R}^2 \setminus \{(n, 0) \,|\, n \in \mathbb{Z}\}$ and let X be the surface of infinite genus that is shown in the figure below. Show that W and X are not diffeomorphic.

Hint. What compact submanifolds can occur?
Remark. The same argument also shows that W is not diffeomorphic to the other surfaces of "infinite genus" that are shown in the figure below.
Remark. Later in Exercise 115.5 we will see that W and X are not homeomorphic. With the present knowledge it is at best quite challenging to give a watertight proof that W and X are not homeomorphic.

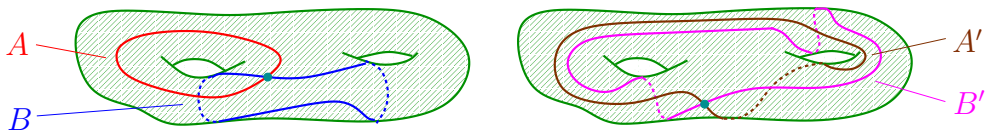


Exercise 55.15. Let X be a topological space. Given a compact subset $K \subset X$ we define $m(K)$ to be the number of non-compact path-components of $X \setminus K$ that are *not* contained in a compact subset of X. As in Exercise 2.27 we refer to

$$\mathrm{End}(X) \;:=\; \max\{m(K) \,|\, K \text{ is a compact subset of } X\} \in \mathbb{N}_0 \cup \{\infty\}$$

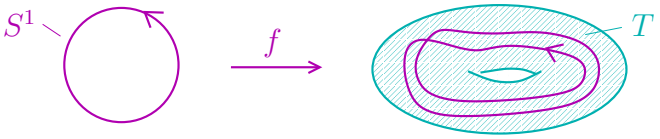
as the *number of ends of* X.

(a) Determine the number of ends for each of the three non-compact surfaces shown in the figure below.
(b) Which (if any) of the three "surfaces of infinite genus" shown in the figure below are homeomorphic?
(c) For each $n \in \mathbb{N}$ give an example of a non-compact connected 2-dimensional smooth manifolds such that the number of ends equals n.



Exercise 55.16. Let $n \in \mathbb{N}$, let M_n be S^2 minus n open disks and let C be a closed curve in $M_n \setminus \partial M_n$.

(a) Show that C is separating.
(b) Let $n = 3$. Show that C either bounds a disk or that it is isotopic to a boundary component of M_n.
(c) Show that the conclusion of (b) is in general not true for $n \geq 4$.



Exercise 55.17. Let Σ be a closed orientable connected 2-dimensional smooth manifold and let $\{A, B\}$ and $\{A', B'\}$ be pairs of closed curves on Σ such that A intersects B transversally in a single point and such that A' intersects B' transversally in a single point.

(a) Show that there exists a diffeomorphism $f\colon \Sigma \to \Sigma$ with $f(A) = A'$ and $f(B) = B'$.
Remark. The statement of this exercise, and of the closely related Curves-on-Surfaces-Classification Theorem 55.16, are proved and extended, in [**FaM2011**, Chapter 1.3]. They refer to statements of this type as the *change of coordinates principle*.

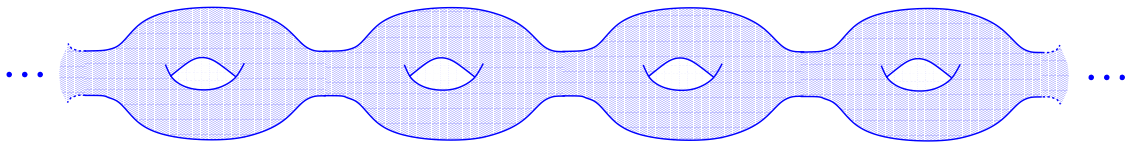
(b) Suppose that all the curves are oriented. Can we find f such that the maps $f\colon A \to A'$ and $f\colon B \to B'$ are both orientation-preserving?

Exercise 55.18. Show that the map $f\colon S^1 \to T = S^1 \times S^1$ that is shown in the figure below is not homotopic to a smooth embedding.
Remark. This settles an issue that arose on page **??**.

Exercise 55.19. We set

$$\begin{array}{rcll} H & := & \{(x,y) \in \mathbb{R}^2 \,|\, y > 0\} & \text{the open half-plane} \\ A & := & \{(x,0) \,|\, x < -1\} & \\ B & := & \{(x,0) \,|\, x > 1\}. & \end{array}$$

We consider the smooth manifold $M = H \cup A \cup B$. A *track* from A to B is a connected oriented proper 1-dimensional smooth manifold T of M such that $\partial T = \{-P\} \cup \{Q\}$ where $P \in A$ and $Q \in B$.



(a) Show that if S and T are two tracks from A to B, then there exists a proper smooth isotopy from S to a track S' and from T to a track T' such that S' and T' are disjoint.

(b) Show that all tracks from A to B are smoothly isotopic.

56. Limits

The goal of this section is to determine the fundamental group of "unbounded spaces", e.g. we would like to determine the fundamental group of the surface of "infinite genus" illustrated in the figure below.[626] One idea might be to view the surface of "infinite genus" as the limit of a sequence given by compact surfaces. But then we need to make precise what we mean by a "limit of topological spaces" and "limit of the corresponding fundamental groups". We will do so in the following sections.

surface of "infinite genus"

56.1. **Preordered and directed sets.** The following definition partly recalls some notions that we introduced on page 89.

Definition. Let X be a set and let $\leq$ be a relation on X.

(1) The relation is called reflexive if for every $x \in X$ we have $x \leq x$.
(2) The relation is called transitive if for every $x, y, z \in X$ we have
$$x \leq y \text{ and } y \leq z \quad \Longrightarrow \quad x \leq z.$$
(3) A reflexive and transitive relation is called a preorder.
(4) A set together with a preorder is called a preordered set.
(5) A directed set is a preordered set such that for any $x, y \in X$ there exists a $z \in X$ with $x \leq z$ and $y \leq z$.

Examples.

(1) Let X be a subset of $\mathbb{R}$ and denote by $\leq$ the usual "less or equal" relation on the real numbers. Then $(X, \leq)$ is a directed set. In particular $(\mathbb{N}, \leq)$ is a directed set.
(2) Given any set X the relation "$\leq$" where $x \leq y$ only if $x = y$ is a preorder, which we call the *trivial preorder* on X.
(3) Let M be a set. We denote by $\mathcal{P}(M)$ the power set of M, i.e. the set of all subsets of M. Then "being a subset", i.e. the relation given by "$\subseteq$", defines a preorder on $\mathcal{P}(M)$. Thus $(\mathcal{P}(M), \subseteq)$ is a preordered set, in fact it is straightforward to see that it is even a directed set.
(4) The set $X = \{0, x, y\}$ with the trivial relations $0 \leq 0, x \leq x, y \leq y$ and the non-trivial relations $0 \leq x$ and $0 \leq y$ is a preordered set. We refer to $(\{0, x, y\}, \leq)$ as the *push-pull set*. Note that this is not a directed set, since there is no $z \in X$ with $x \leq z$ and $y \leq z$.
(5) We consider the set $\mathbb{N}$. The divisibility relation $k|l$ for $k, l \in \mathbb{N}$ is a preorder on $\mathbb{N}$ and with this preorder $\mathbb{N}$ is in fact a directed set.[627]

[626] Actually we also need to make precise what we mean by the surface of "infinite genus".
[627] Indeed, given $k, l \in \mathbb{N}$ we have $k|kl$ and $l|kl$.

56.2. The direct limit of a direct system.

Definition. Let $(I, \leq)$ be a preordered set[628] and let $\mathcal{C}$ be a category. A direct system in the category $\mathcal{C}$ over I is a family of objects $\{X_i\}_{i\in I}$ in $\mathcal{C}$, together with a family of morphisms $\{f_{ij}\colon X_i \to X_j\}$ for all $i, j \in I$ with $i \leq j$ such that the following two conditions are satisfied:

$$\begin{array}{lrcll} (1) & f_{ii} & = & \mathrm{id}_{X_i} & \text{for all } i \in I, \\ (2) & f_{ik} & = & f_{jk} \circ f_{ij} & \text{for all } i, j, k \in I \text{ with } i \leq j \leq k. \end{array}$$

Examples.

(A) We consider the directed set $I = (\mathbb{N}, \leq)$ and the category of groups. For $i \in \mathbb{N}$ we consider the group $\mathbb{Z}^i$ and for $i \leq j$ we denote by

$$\begin{array}{rcl} f_{ij}\colon \mathbb{Z}^i & \to & \mathbb{Z}^j \\ (x_1, \ldots, x_i) & \mapsto & (x_1, \ldots, x_i, 0, \ldots, 0) \end{array}$$

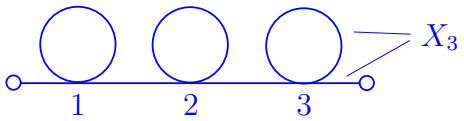
the inclusion map. Then $(\{\mathbb{Z}^i\}_{i\in\mathbb{N}}, \{f_{ij}\}_{i\leq j})$ forms clearly a direct system.

(B) Again we consider $I = (\mathbb{N}, \leq)$ and the category of groups. Given $i \in \mathbb{N}$ we define

$$F_i \;:=\; \langle x_1, \ldots, x_i \rangle \;=\; \text{the free group on } i \text{ generators}$$

and given $i \leq j$ we set

$$\begin{array}{rcl} f_{ij}\colon F_i & \to & F_j \\ x_k & \mapsto & x_k, \text{ for } k = 1, \ldots, i. \end{array}$$



This is clearly a direct system of groups.

(C) Given $r \in \mathbb{N} \cup \{\infty\}$ we set

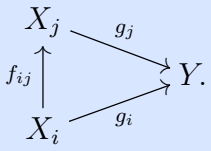
$$X_r \;:=\; \big(0, r + \tfrac{1}{2}\big) \;\cup\; \bigcup_{j=1}^{r} \underbrace{\big\{z \in \mathbb{C} \,\big|\, \big|z - (j + \tfrac{1}{4}i)\big| = \tfrac{1}{4}\big\}}_{\text{circle of radius } \frac{1}{4} \text{ around } j + \frac{1}{4}i \in \mathbb{C}} \;\subset\; \mathbb{C}.$$

For example, for $r \in \mathbb{N}$ the set X_r is the subset of $\mathbb{C} = \mathbb{R}^2$ that is given by the interval $(0, r + \frac{1}{2})$ with r circles attached. We refer to the figure below for an illustration.

Now we consider the directed set $(\mathbb{N}, \leq)$ and for $r \leq s$ we denote by $f_{rs}\colon X_r \to X_s$ the obvious inclusion map. This is clearly a direct system of topological spaces.

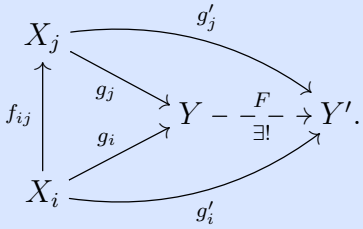
(D) We can generalize example (C) as follows. Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i\in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. Given $i \leq j$ we denote by $\iota_{ij}\colon X_i \to X_j$ the inclusion map. Then $(\{X_i\}_{i\in I}, \{\iota_{ij}\}_{i\leq j})$ is a direct system in the category of topological spaces.

(E) Let $(\{0, x, y\}, \leq)$ be the push-pull set and let $\mathcal{C}$ be a category. A direct system in the category $\mathcal{C}$ over the preordered set $(\{0, x, y\}, \leq)$ consists of three objects A_0, A_x, A_y, the identity morphisms $\mathrm{id}_{A_0}, \mathrm{id}_{A_x}, \mathrm{id}_{A_y}$ and morphisms $f_x\colon A_0 \to A_x$ and



[628] In the literature one often demands that I is a directed set, see e.g. [**Hat2002**, p. 243], but this is not necessary.

$f_y\colon A_0 \to A_y$. We refer to such a system as a *pushout system* and often we arrange the morphisms in a diagram as follows



$$\begin{array}{ccc} A_0 & \xrightarrow{f_x} & A_x \\ {\scriptstyle f_y}\downarrow & & \\ A_y. & & \end{array}$$

Definition. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be a category. Suppose we are given a direct system $(\{X_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ in the category $\mathcal{C}$. A direct limit[629] of the direct system is an object Y in $\mathcal{C}$ together with morphisms $g_i\colon X_i \to Y, i \in I$ in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $i \leq j$ we have $g_j \circ f_{ij} = g_i\colon X_i \to Y$, i.e. for all $i \leq j$ the following diagram commutes

(2) If we are given another object Y' and morphisms $g_i'\colon X_i \to Y', i \in I$ that satisfy (1), then there exists a unique morphism $F\colon Y \to Y'$ such that for all $i \leq j$ the following diagram commutes[630]

The "usual argument" for objects that satisfy a universal property[631] shows that if the direct limit exists, then it is unique in an appropriate sense. We denote the direct limit by $\varinjlim X_i$ or sometimes by $\varinjlim_I X_i$.[632]

Examples. Now we discuss the direct limits of the direct systems we had discussed above.

(A) We consider the above direct system in the category of groups that is given by the free abelian groups $\mathbb{Z}^i$, $i \in \mathbb{N}$, with the obvious inclusion homomorphisms $\mathbb{Z}^i \to \mathbb{Z}^j$ for $i \leq j$. We claim that[633]

$$\varinjlim \mathbb{Z}^i \;=\; \mathbb{Z}^{(\mathbb{N})} \;=\; \{(x_1, x_2, \dots) \mid x_i \in \mathbb{Z} \text{ but only finitely many } x_i\text{'s are non-zero}\},$$

[629] Somewhat confusingly a "direct limit" is often also called a "projective limit" or "colimit of a direct system".

[630] The notation $\exists!$ means that there exists a uniquely defined morphism that makes the diagram commute.

[631] See for instance the discussion on page 1149 for an example of such an argument.

[632] Here we ignore the maps f_{ij} and g_i in the notation. Usually these maps are clear from the context.

[633] Why is the direct limit not given by $\mathbb{Z}^{\mathbb{N}}$, i.e. the group of all infinite sequences?

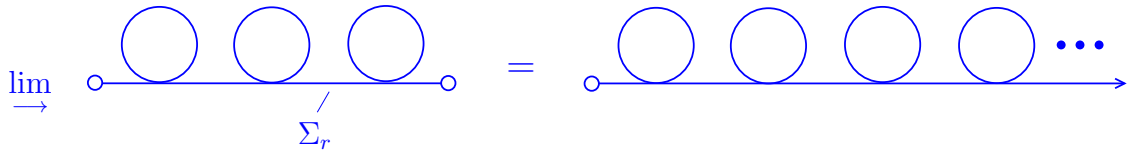
where the maps $\mathbb{Z}^j \to \varinjlim \mathbb{Z}^i = \mathbb{Z}^{(\mathbb{N})}$, $j \in \mathbb{N}$ are the obvious inclusion maps. Indeed, given a group Y' and homomorphisms $g'_j \colon \mathbb{Z}^j \to Y'$ that satisfy condition (1) we define

$$\begin{array}{rcl} F \colon \varinjlim \mathbb{Z}^i \ = \ \mathbb{Z}^{(\mathbb{N})} & \to & Y' \\ (x_1, \dots, x_j, 0, \dots) & \mapsto & g'_j(x_1, \dots, x_j). \end{array}$$

It is straightforward to see that this definition is well-defined, i.e. independent of the choice of x_j.[634] It is clear that the diagram (2) commutes. Furthermore, since $(x_1, \dots, x_j, 0, \dots) = g_j(x_1, \dots, x_j)$ it is clear that F is the unique homomorphism that makes the diagram (2) commute.

Thus we have now shown that the direct limit is the free abelian group on an infinite countable generating set.

(B) We consider the above direct system in the category of groups that is given by the free groups $F_i := \langle x_1, \dots, x_i \rangle$, $i \in \mathbb{N}$, with the obvious inclusion homomorphisms $F_i \to F_j$ for $i \leq j$. Similar to the proof of (A) one can show that



$$\varinjlim F_i \ = \ \langle x_1, x_2, x_3, \dots \rangle \ = \ \text{free group on the generators } x_1, x_2, x_3, \dots$$

where the maps $F_j \to \varinjlim F_i = \langle x_1, x_2, \dots \rangle$, $j \in \mathbb{N}$ are the obvious maps. Put differently, the direct limit is the free group on an infinite countable generating set.

(C) We continue with the direct system $(X_r, r \in \mathbb{N})$ in the category of topological spaces from above. Perhaps not surprisingly the direct limit is the interval $(0, \infty)$ with infinitely many circles attached, i.e.

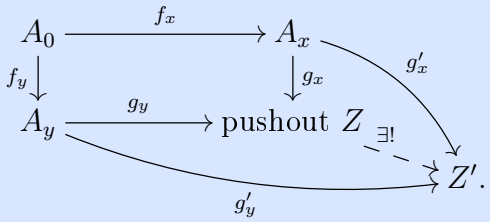
$$\varinjlim X_r \ = \ X_\infty \ = \ (0, \infty) \ \cup \ \bigcup_{j=1}^{\infty} \left\{ z \in \mathbb{C} \,\middle|\, \left| z - (j + \tfrac{1}{4} i) \right| = \tfrac{1}{4} \right\} \ \subset \ \mathbb{C},$$

where the maps $X_s \to \varinjlim X_r = X_\infty$, $s \in \mathbb{N}$ are the obvious inclusion maps. We leave the verification of this statement to the reader.

(D) Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i \in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. In the category of topological spaces we have

$$\varinjlim X_i \ = \ X \ := \ \bigcup_{i \in I} X_i,$$

where the topology on $X = \bigcup_{i \in I} X_i$ is given by the rule that $U \subset X$ is open if and only if $U \cap X_i$ is open for all $i \in I$. Furthermore the maps $g_j \colon X_j \to X = \bigcup_{i \in I} X_i$, $j \in \mathbb{N}$ are the obvious inclusion maps.[635] The verification of this statement is Exercise 56.5.



[634] Here we did not demand that $x_j \neq 0$.

[635] Why are the maps g_j continuous, i.e. why are they morphisms in the category of topological spaces.

Definition. If the direct limit of a pushout system

$$\begin{array}{ccc} A_0 & \xrightarrow{f_x} & A_x \\ {\scriptstyle f_y}\downarrow & & \\ A_y & & \end{array}$$

exists, then we refer to it as the pushout of the pushout system. The defining property of the pushout Z can be summarized in the following commutative diagram[636]

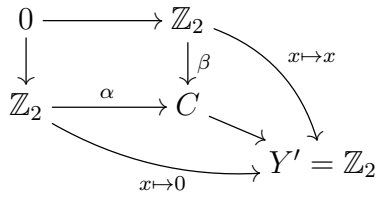
Examples.

(1) We first consider the pushout in the category of groups. By Proposition 53.21 the pushout of a pushout system in the category of groups

$$\begin{array}{ccc} G & \xrightarrow{\alpha} & A \\ {\scriptstyle \beta}\downarrow & & \\ B & & \end{array} \qquad \text{is given by} \qquad \begin{array}{ccc} G & \xrightarrow{\quad\alpha\quad} & A \\ {\scriptstyle \beta}\downarrow & & \downarrow \\ B & \longrightarrow & A *_G B = \dfrac{A * B}{\langle\langle \{\alpha(g) \cdot \beta(g)^{-1}\}_{g \in G} \rangle\rangle}. \end{array}$$

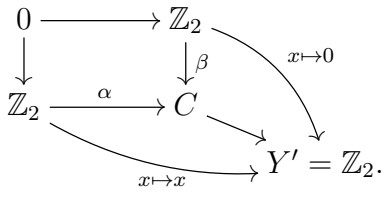
(2) Now we consider the pushout in the category of topological spaces. In the Topological Pushout Proposition 5.33 we already showed, in ever so slightly different words, that the pushout of the pushout system of topological spaces

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle g}\downarrow & & \\ Z & & \end{array} \qquad \text{is given by} \qquad \begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ {\scriptstyle g}\downarrow & & \downarrow \\ Z & \longrightarrow & Y \cup_X Z := (Y \sqcup Z)/f(x) \sim g(x). \end{array}$$



Here we equip $Y \cup_X Z$ with the quotient topology induced from the obvious topology on $Y \sqcup Z$.

(3) The direct limit of a direct system does not always exist. For example, denote by $\mathcal{C}$ the category with two objects, namely the trivial group and the group $\mathbb{Z}_2$, and where the morphisms are the usual group homomorphisms. Then the pushout system



$$\begin{array}{ccc} 0 & \longrightarrow & \mathbb{Z}_2 \\ \downarrow & & \\ \mathbb{Z}_2 & & \end{array} \qquad \begin{array}{c} \text{does not have a direct limit} \\ \text{since there is no commutative} \\ \text{diagram of the form} \end{array} \qquad \begin{array}{ccc} 0 & \longrightarrow & \mathbb{Z}_2 \\ \downarrow & & \downarrow{\scriptstyle \beta} \\ \mathbb{Z}_2 & \xrightarrow{\alpha} & C \end{array}$$

[636] Here we suppress the morphism $g_0 \colon A_0 \to Z$ from the diagram since it is given by $g_x \circ f_x = g_y \circ f_y$.

with $C = 0$ or $C = \mathbb{Z}_2$ such that in the following two diagrams there exists the desired diagonal maps from C to $Y' = \mathbb{Z}_2$:[637]

and

Proposition 56.1. (Direct Limit Existence Proposition) The direct limit of any direct system exists in the following categories:

(0) the category of sets,
(1) the category *Top* of topological spaces,
(2) the category *Group* of groups,
(3) the category *AbGroup* of abelian groups,
(4) the category *Ring* of rings,
(5) the category R-*Mod* of R-modules, where R is a commutative ring.

Sketch of proof. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be one of the six given categories. Furthermore let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system in $\mathcal{C}$.

(0),(1) If we work in the category of sets, then we define the direct limit as the set

$$\varinjlim X_i \ := \ \Big(\bigsqcup_{i\in I} X_i\Big)/\sim \quad \text{where } x \sim f_{ij}(x) \text{ for all } i \leq j,\ x \in X_i.$$

If we work in the category of topological spaces, then $\bigsqcup_{i\in I} X_i$ is equipped with the topology where a subset U is open if and only if $U \cap X_i$ is open for all i.[638]

(2) If we work in the category of groups, then we cannot use the definition of (0) and (1), since the union of groups is not a group. Therefore we define the direct limit via the "smallest group that contains all X_i", i.e. we define it as the group

$$\varinjlim X_i \ := \ \Big(\mathop{*}_{i\in I} X_i\Big)/\langle\langle\{f_{ij}(x)\cdot x^{-1} \mid i \leq j \text{ and } x \in X_i\}\rangle\rangle.$$

(3),(4),(5) If we work in the category of abelian groups, or in the category of rings or in the category of R-modules, then we define[639]

$$\varinjlim X_i \ := \Big(\bigoplus_{i\in I} X_i\Big)/\{f_{ij}(x) - x \mid \ i \leq j \text{ and } x \in X_i\}.$$

Furthermore in all six cases we denote by $g_j\colon X_j \to \varinjlim X_i$, $j \in I$ the obvious maps. It is now straightforward to verify that in all five categories we provided a direct limit. We leave the details to the reader. ∎

[637] Why is there no such diagram with $C = 0$ or $C = \mathbb{Z}_2$ and homomorphisms α and β?

[638] Note that for the above example of the pushout we do *not* get the same topological space (why not?) but we get a topological space that is homeomorphic (why?) to the above pushout. Since we only care about the direct limit up to homeomorphism this makes no difference.

[639] Here we really mod out by the subgroup generated by the differences $f_{ij}(x) - x$.

Remark.

(1) Suppose we are given a direct system $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ in any of the four algebraic categories mentioned in the previous proposition. Now we assume that $(I, \leq)$ is not only a preordered set, but that it is in fact a directed set. Then, as for direct limits of sets and topological spaces, we can also define

$$\varinjlim X_i \;:=\; \Big(\bigsqcup_{i\in I} X_i\Big)/\sim \quad \text{where } x \sim f_{ij}(x) \text{ for all } i \leq j,\ x \in X_i$$

and we denote by $g_j\colon X_j \to \varinjlim X_i$, $j \in I$, the obvious maps. If we work in the category of groups, then $\varinjlim X_i$ is naturally a group as follows: if we are given $a \in X_i$ and $b \in X_j$, by definition of a directed set there exists $k \in I$ with $i \leq k$ and $j \leq k$, and we define

$$[a] \cdot [b] \;:=\; \big[\underbrace{f_{ik}(a)}_{\in X_k} \cdot \underbrace{f_{jk}(b)}_{\in X_k}\big] \;\in\; \varinjlim X_i.$$

It follows easily from the definition of a direct system that this definition of the product structure is independent of the choice of k and that this defines indeed a group structure on $\varinjlim X_i$. Similarly we deal with the case that we work in the other three algebraic categories.

(2) An important special case is given by $I = \mathbb{N}_0$ and where the maps $f_{ij}\colon X_i \to X_j$ are inclusion maps. In this case one can in fact take

$$\varinjlim X_i \;:=\; \bigcup_{i\in\mathbb{N}_0} X_i.$$

The algebraic structure is defined as in the previous remark.

We continue our discussion with the following lemma that gives a particularly simple but commonly used calculation of a direct limit.

Lemma 56.2. (Direct Limit Stabilization Lemma) Let $f_n\colon X_n \to X_{n+1}$ be a sequence of morphisms in any category. Suppose there exists an $N \in \mathbb{N}$ such that all f_n for $n \geq N$ are isomorphisms. Then $\varinjlim X_n$ exists and it is naturally isomorphic to X_N, more precisely, a direct limit is given by $\varinjlim X_n := X_N$ and the maps

$$\begin{aligned} f_{N-1} \circ \cdots \circ f_{n+1} \circ f_n\colon X_n &\to X_N \quad \text{if } n \leq N, \\ (f_n \circ \cdots \circ f_{N+1} \circ f_N)^{-1}\colon X_n &\to X_n \quad \text{if } n > N \end{aligned}$$

define a direct limit.

Proof. We will provide the proof in Exercise 56.4. ∎

56.3. **The direct limit in the topological category.** In this short section we discuss a few results about direct limits that are specific to the category of topological spaces. We start out with the discussion of an important example of direct limits in the topological category.

Lemma 56.3. (Direct Limit-of-Topological Spaces Lemma) Let $(\{X_i\}_{i\in\mathbb{N}_0}, \{f_{ij}\}_{i\leq j})$ be a direct system in the category of topological spaces. We assume that all the maps $f_{ij}\colon X_i \to X_j$ are inclusion maps.

(1) In this case one can in fact take

$$\varinjlim X_i \;:=\; \bigcup_{i\in\mathbb{N}_0} X_i$$

where the topology is given, as in the proof of the Direct Limit Existence Proposition 56.1, by the condition that $U \subset X$ is open if and only if each $U \cap X_i$ is an open subset of X_i.

(2) For each $i \in \mathbb{N}$ the obvious map $X_i \to \varinjlim X_i$ is an embedding.

Proof.

(1) The argument is the same as in the proof of the Direct Limit Existence Proposition 56.1 (1).

(2) Let $i \in \mathbb{N}$. The map $X_i \to \varinjlim X_i$ is evidently injective and continuous. By the Open -Injective Map Lemma 2.16 (1) it remains to show that the map is an open map. Thus let $U_i \subset X_i$ be an open subset. By definition of the subspace topology there exists an open subset $U_{i+1} \subset X_{i+1}$ such that $U_{i+1} \cap X_i = U_i$. We iterate this procedure to obtain subsets $U_i, U_{i+1}, U_{i+2}, \ldots$. We set $U := \bigcup_{j\geq n} U_j$. Evidently $U \cap X_i = U_i$. ■

Finally we conclude this section with two lemmas which show that in the category of topological spaces direct limits commute, under favorable circumstances, with direct products and quotients.

Lemma 56.4. (Direct Limits-and-Products Lemma) Let $(I, \leq)$ be a preordered set and let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system in the category of topological spaces. We denote by $g_i\colon X_i \to \varinjlim X_i$ the canonical maps. Furthermore let Y be a topological space. By definition of the direct limit the maps

$$g_i \times \mathrm{id}_Y\colon X_i \times Y \;\to\; (\varinjlim X_i) \times Y$$

induce a map

$$\varinjlim (X_i \times Y) \;\to\; \big(\varinjlim X_i\big) \times Y.$$

If Y is regionally compact, then this map is a homeomorphism.

Example. Let $f\colon X \to Y$ and $g\colon X \to Z$ be maps between topological spaces. These maps define a pushout system, and taking the product with $[0,1]$ also defines a pushout system. We get the following two diagrams:

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle i} \\ Z & \xrightarrow{j} & X \cup_Y Z \end{array} \qquad \text{and} \qquad \begin{array}{ccc} X\times[0,1] & \xrightarrow{f\times\mathrm{id}} & Y\times[0,1] \\ {\scriptstyle g\times\mathrm{id}}\downarrow & & \downarrow{\scriptstyle I} \\ Z\times[0,1] & \xrightarrow{J} & X\times[0,1]\cup_{Y\times[0,1]} Z\times[0,1] \end{array}$$

$i\times\mathrm{id}$: $Y\times[0,1] \to (X\cup_Y Z)\times[0,1]$; $j\times\mathrm{id}$: $Z\times[0,1] \to (X\cup_Y Z)\times[0,1]$.

By the property of the pushout we have the diagonal map. Since $[0,1]$ is regionally compact we obtain from the Direct Limits-and-Products Lemma 56.4, or more directly from the Product-Quotient Mixing Lemma 13.6, that the diagonal map is a homeomorphism.

Sketch of proof. This lemma follows easily from the explicit description of the direct limit in the category of topological spaces that we gave in the Direct Limit Existence Proposition 56.1 together with the Product-Quotient Mixing Lemma 13.6. ■

Lemma 56.5. Let $(I, \leq)$ be a preordered set and let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system in the category of topological spaces. Let G be a group. Suppose that for each $i \in I$ we are given an action of G on X_i such that given any $i \leq j$ the following diagram commutes:

$$\begin{array}{ccc} G \times X_i & \longrightarrow & X_i \\ \downarrow{\scriptstyle \mathrm{id}_G \times f_{ij}} & & \downarrow{\scriptstyle f_{ij}} \\ G \times X_j & \longrightarrow & X_j. \end{array}$$

It follows almost immediately from this data that G also acts on $\varinjlim X_i$. We denote by $g_i\colon X_i \to \varinjlim X_i$ the canonical maps. By definition of the direct limit the corresponding maps

$$X_i/G \;\to\; (\varinjlim X_i)/G$$

induce a map

$$\varinjlim (X_i/G) \;\to\; \big(\varinjlim X_i\big)/G.$$

This map is a homeomorphism.

Sketch of proof. This lemma follows easily from the explicit description of the direct limit in the category of topological spaces that we gave in the Direct Limit Existence Proposition 56.1. ■

56.4. **Fundamental groups and direct limits.** In this section we want to address the following question:

Question 56.6. Let $(\{X_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ be a direct system of topological spaces. Now we can form the direct limit $\varinjlim X_i$ of the topological spaces. The maps f_{ij} also induce homomorphisms on fundamental groups. The question is, when does "taking limits commute with taking fundamental groups", i.e. under what circumstances do we have[640]

$$\pi_1\big(\varinjlim X_i\big) \;=\; \varinjlim \pi_1(X_i)\ ?$$

Example. We have already seen two instances where the equality of the question holds.

(1) Suppose X is a topological space that is the union of two open subsets U and V such that U, V and $U \cap V$ are path-connected. We fix a base point in $U \cap V$. Then

$$\pi_1\left(\varinjlim \begin{array}{c} U\cap V \to U \\ \downarrow \\ V \end{array}\right) \;=\; \pi_1(X) \;=\; \pi_1(U) *_{\pi_1(U\cap V)} \pi_1(V) \;=\; \varinjlim \begin{array}{c} \pi_1(U\cap V) \to \pi_1(U) \\ \downarrow \\ \pi_1(V) \end{array}$$

see page 1260 — Seifert–van Kampen Theorem 54.1 — see page 1260

[640] As it is this question is not well-phrased, since fundamental groups depend on base points and we ignored them in the above discussion.

(2) Let X be a path-connected topological space and let X_k, $k \in \mathbb{N}$ be a sequence of subsets of X such that the following hold:
   (a) each X_k is open,
   (b) each X_k is simply connected,
   (c) the sequence X_k is nested, i.e. for each k we have $X_k \subset X_{k+1}$,
   (d) we have $\bigcup\limits_{k\in\mathbb{N}} X_k = X$.

   Then for any $w \in X_1$ we have[641]

$$\pi_1\big(\varinjlim X_i, w\big) \underset{\uparrow}{=} \pi_1\Big(\bigcup_{i\in\mathbb{N}} X_i, x_0\Big) \underset{\uparrow}{=} \{e\} = \varinjlim \{e\} = \varinjlim \pi_1(X_i, w).$$

see the Direct Limit-of-Topological Spaces Lemma 56.1 Lemma 52.6

The following proposition generalizes the second example.

Proposition 56.7. (Direct Limit-π_1-Proposition) Let $X_i, i \in \mathbb{N}$ be a sequence of topological spaces such that the following holds:

(1) the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$,

and such that one of the following two conditions holds:

(2) every compact subset of $\varinjlim X_i$ is already contained in one of the X_i, or

(3) each X_i is open in X_{i+1}.

Then for any $w \in X_1$ we have

$$\pi_1\big(\varinjlim X_i, w\big) = \varinjlim \pi_1(X_i, w).$$

Remark. We will see that the proof of the Direct Limit-π_1-Proposition 56.7 is a generalization of the ideas behind the proof of Lemma 52.6.

The following lemma shows that the hypothesis (3) in the Direct Limit-π_1-Proposition 56.7 implies in fact hypothesis (2).

Lemma 56.8. Let $X_i, i \in \mathbb{N}$ be a sequence of topological spaces such that each X_i is open in X_{i+1}. Then every compact subset of $\varinjlim X_i$ is already contained in one of the X_i.

Proof of Lemma 56.8. Let $X_i, i \in \mathbb{N}$ be a nested sequence of topological spaces such that each X_i is open in X_{i+1}.

Claim. For every $i \in \mathbb{N}$ the subset X_i is open in X.

Proof. By the definition of the topology on X we have to show that for each $j \in \mathbb{N}$ the intersection $X_i \cap X_j$ is open in X_j. Since the sequence is nested it follows that for $j \leq i$ we have $X_i \cap X_j = X_j$, in particular $X_i \cap X_j$ is open in X_j. Now we need to show that X_i is open in any X_{i+k} with $k \in \mathbb{N}_0$. We do so by induction on k. For $k = 0$ the statement is clear. Suppose we already know that X_i is open in X_{i+k}. Then X_i is an open subset in

[641] Recall that by the discussion on page 1257 the topological spaces $\{X_i\}_{i\in\mathbb{N}}$ together with the inclusion maps form a direct system in the category of topological spaces. The direct limit is given by the union of all X_i's, where the union is given a suitable topology. Furthermore note that the inclusion induced maps $\pi_1(X_i, w) \to \pi_1(X_j, w)$ turn the groups $\{\pi_1(X_i, w)\}_{i\in\mathbb{N}}$ into a direct system in the category of groups.

X_{i+k} and X_{i+k} is in turn an open subset of X_{i+k+1} by our hypothesis. It follows that X_i is open in X_{i+k+1}.[642] ⊞
Now let $K \subset \varinjlim X_i$ be a compact subset. From the claim we know that each X_i is open in $X = \varinjlim X_i$ we obtain immediately from Lemma 2.12 and the hypothesis that the X_i's are nested that there exists a $k \in \mathbb{N}$ such that $K \subset X_i$. ■

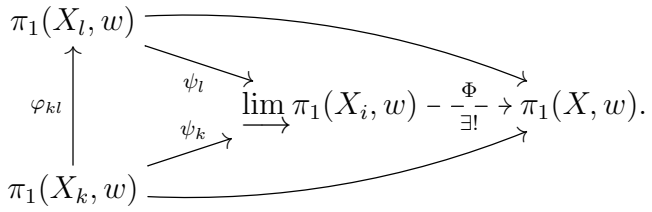
The proof of the Direct Limit-π_1-Proposition 56.7 also relies on the following lemma that we will use implicitly and explicitly on numerous occasions.

Lemma 56.9. Let (X, x_0) be a pointed topological space.

(1) Given any $g \in \pi_1(X, x_0)$ there exists a compact subset K of X with $x_0 \in K$ such that g lies in the image of the inclusion induced map $\pi_1(K, x_0) \to \pi_1(X, x_0)$.
(2) Let Y be a subset of X with x_0. If $g \in \pi_1(Y, x_0)$ lies in the kernel of the inclusion induced map $\pi_1(Y, x_0) \to \pi_1(X, x_0)$, then there exists a compact subset K of X such that g lies in the kernel of the inclusion induced map $\pi_1(Y, x_0) \to \pi_1(Y \cup K, x_0)$.

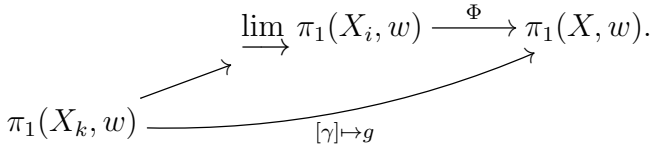
Proof.

(1) Let $g \in \pi_1(X, x_0)$. We represent g by a loop $\gamma\colon [0,1] \to X$. By the Compact Image Lemma 2.13 the image $\gamma([0,1])$ is compact. Thus $K := \gamma([0,1])$ has the desired property.
(2) Now suppose that we are given $g = [\gamma] \in \pi_1(Y, x_0)$ that lies in the kernel of the inclusion induced map $\pi_1(Y, x_0) \to \pi_1(X, x_0)$. By definition this means that there exists a path-homotopy $H\colon [0,1] \times [0,1] \to X$ from the path γ to the constant path. We appeal again to the Compact Image Lemma 2.13 to deduce that $K := H([0,1] \times [0,1])$ is a compact subset of X. Evidently K has the desired property. ■



Now we can provide the proof of the Direct Limit-π_1-Proposition 56.7.

Proof of the Direct Limit-π_1-Proposition 56.7. By Lemma 56.8 we only have to prove the proposition under the hypothesis (2). Thus let $X_i, i \in \mathbb{N}$ be a nested sequence of topological spaces such that every compact subset of $\varinjlim X_i$ is already contained in one of the X_i. Let $w \in X_1$. We write $X = \bigcup_{i \in I} X_i = \varinjlim X_i$.

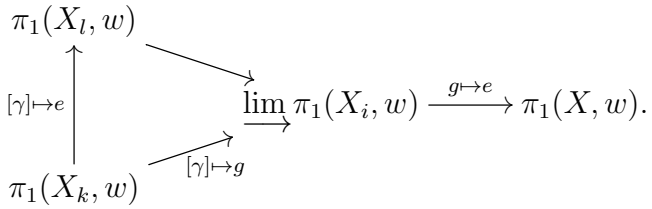


Given $k \leq l$ we denote by φ_{kl} the inclusion induced map $\pi_1(X_k, w) \to \pi_1(X_l, w)$. We denote by $\Phi\colon \varinjlim \pi_1(X_i, w) \to \pi_1(X, w)$ the unique homomorphism that makes the

[642] Here we use the following general fact: if U is an open subset in V and V is an open subset of W, then U is an open subset of W. Why is that true?

following diagram commute for any $k \leq l$:

We need to show that Φ is an isomorphism. First we show that the map Φ is surjective. Let $g \in \pi_1(X, w)$. By Lemma 56.9 (1) and our hypothesis (2) there exists a $k \in \mathbb{N}$ such that g lies in the image of the inclusion induced map $\pi_1(X_k, w) \to \pi_1(X, w)$. We consider the following commutative diagram



By our choice of k we see that g lies in the image of the curved map, hence it also lies in the image of Φ. This concludes the proof that Φ is surjective.

Now we show that the map Φ is injective. So let $g \in \varinjlim \pi_1(X_i, w)$. Since $(\mathbb{N}, \leq)$ is a directed set we can use the description of the direct limit from page 1262, i.e. we can write

$$\varinjlim \pi_1(X_i, w) \;=\; \Big(\bigsqcup_{i \in \mathbb{N}} \pi_1(X_i, w) \Big) / \sim \quad \text{where } g \sim \varphi_{kl}(g) \text{ for all } k \leq l,\ g \in \pi_1(X_k, w).$$

In particular we see that there exists a k such that g lies in the image of the map $\psi_k \colon \pi_1(X_k, w) \to \varinjlim \pi_1(X_k, w)$. It follows from Lemma 56.9 (1) and our hypothesis (2) that there exists an $l \geq k$ such that $\varphi_{kl}([\gamma])$ is trivial in $\pi_1(X_l, w)$. We obtain the following diagram

It follows immediately that g itself is trivial. This concludes the proof that Φ is injective. ■

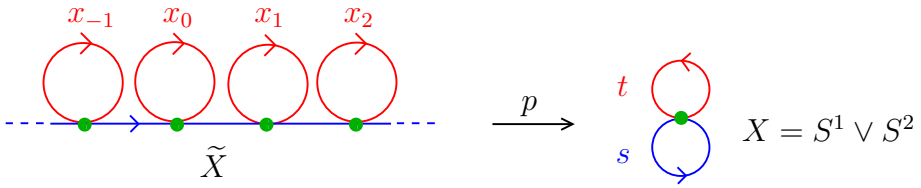
Examples.

(1) As on page 1257 we denote by X_∞ the interval $(0,\infty)$ with infinitely many circles attached. We pick the base point $w = \frac{1}{4}$. We then have [643]

$$\pi_1\big(X_\infty, w\big) \underset{\uparrow}{=} \pi_1\big(\varinjlim X_r, w\big) \underset{\uparrow}{=} \varinjlim \pi_1\big(X_r, w\big) \underset{\uparrow}{=} \varinjlim \langle x_1, \dots, x_r\rangle \underset{\uparrow}{=} \langle x_1, x_2, \dots\rangle.$$

see page 1259 — Direct Limit-π_1-Proposition 56.7 — Proposition 52.5 — see page 1259

Furthermore the proof of the Fundamental Group-of-Graph Proposition 52.5 and the above argument show that the generators $x_1, x_2, \dots$ of $\pi_1(X_\infty)$ can be chosen such that x_n, $n \in \mathbb{N}$, corresponds to a loop which goes "once around the n-th circle".



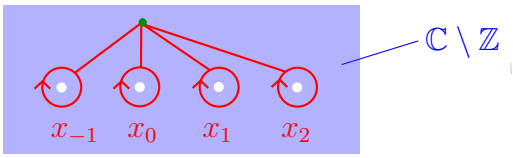
(2) Now we consider

$$\widetilde{X} \;:=\; \mathbb{R} \;\cup\; \bigcup_{j\in\mathbb{Z}} \underbrace{\big\{z \in \mathbb{C} \,\big|\, \big|z - (j + \tfrac{1}{4}i)\big| = \tfrac{1}{4}\big\}}_{\text{circle of radius } \frac{1}{4} \text{ around } j+\frac{1}{4}i \in \mathbb{C}} \;\subset\; \mathbb{C}.$$

Put differently, $\widetilde{X}$ is the real axis with infinitely many circles attached. The same argument as in (1) shows that $\pi_1(\widetilde{X})$ is the free group on infinitely many generators x_n, $n \in \mathbb{Z}$. In the figure below we illustrate a covering map $p\colon \widetilde{X} \to X = S^1 \vee S^1$. By Corollary 48.14 the map $\pi_1(\widetilde{X}) \to \pi_1(X)$ is a monomorphism. We had just seen that $\pi_1(\widetilde{X})$ is a free group on infinitely generators and by the discussion on page 1173 we know that $\pi_1(X)$ is a free group on two generators. In fact, with appropriate orientations and conventions this shows that the homomorphism

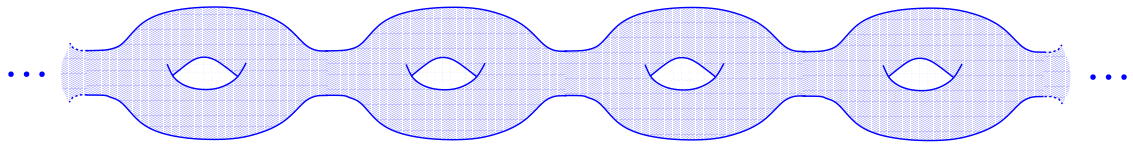
$$\begin{array}{rcl} \pi_1(\widetilde{X}) = \langle \dots, x_{-2}, x_{-1}, x_0, x_1, x_2, \dots\rangle & \to & \langle s, t\rangle = \pi_1(X) \\ x_n & \mapsto & s^n t s^{-n} \end{array}$$

is a monomorphism. In particular we see that the free group $\langle s, t\rangle$ contains a subgroup that is "much larger" than the original free group itself.



(3) An argument similar to (1) shows that $\pi_1(\mathbb{C}\backslash\mathbb{Z})$ is a free group generated by $x_n, n \in \mathbb{Z}$ where x_n is a loop which goes "once around the n-th hole". We leave the task of providing the details to the reader. We refer to the figure below for an illustration.

---



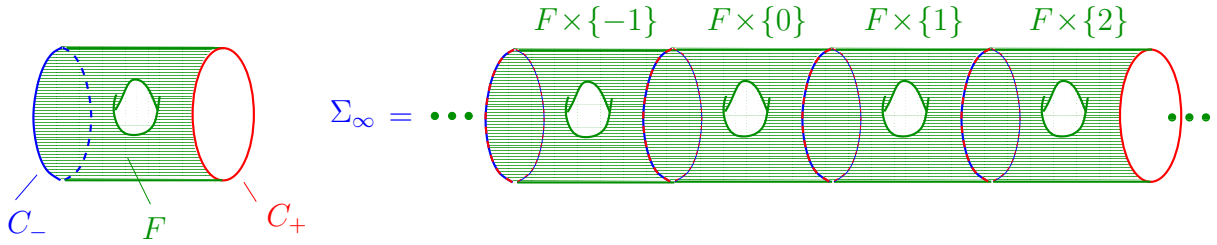
[643] The third equality follows from the Fundamental Group-of-Graph Proposition 52.5, to be more precise, it follows from the fact that for any $r \le s$ the inclusion map $\iota_{rs}\colon X_r \to X_s$ and the isomorphisms of the Fundamental Group-of-Graph Proposition 52.5 give rise to a commutative diagram

$$\begin{array}{ccc} \pi_1(X_r, w) & \xrightarrow{\cong} & \langle x_1, \dots, x_r\rangle \\ {\scriptstyle (\iota_{rs})_*}\downarrow & & \downarrow{\scriptstyle x_i \mapsto x_i} \\ \pi_1(X_s, w) & \xrightarrow{\cong} & \langle x_1, \dots, x_s\rangle. \end{array}$$

The fact that this diagram commutes follows easily from the proof of the Fundamental Group-of-Graph Proposition 52.5. We leave the details to the reader.

56.5. **The surface of "infinite genus".** In this section we return to the initial goal of this chapter, namely we want to determine the fundamental group of the surface of "infinite genus" that we illustrate in the figure below. Before we can calculate its fundamental group we have to give a precise description of the surface of infinite genus.

surface of "infinite genus"



Definition. We write

$$F \;:=\; \text{the torus minus two open disks.}$$

We label the two boundary components by C_- and C_+. We pick orientation-preserving diffeomorphisms $\varphi_\pm \colon S^1 \to C_\pm$. We define

$$\Sigma_\infty \;:=\; \Big(\bigcup_{i\in\mathbb{Z}} (F \times \{i\})\Big)\Big/ \sim \qquad \text{where } (\varphi_+(x), i) \sim (\varphi_-(x), i+1) \text{ for } x \in S^1 \text{ and } i \in \mathbb{Z}.$$

We refer to Σ_∞ as the surface of infinite genus. It should be clear that this definition gives a rigorous description of the surface that we sketched in the figure on page 1269.[644]

Lemma 56.10.

(1) The surface Σ_∞ is a 2-dimensional orientable smooth manifold.

(2) Given $k \in \mathbb{N}$ we write

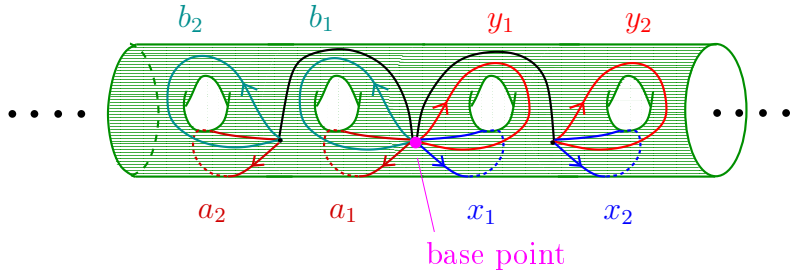
$$X_k \;:=\; \Big(\bigcup_{i=-k+1}^{k} (F \times \{i\})\Big)\Big/ \sim \qquad \begin{array}{l}\text{where } (\varphi_+(x), i) \sim (\varphi_-(x), i+1) \text{ for } x \in S^1 \\ \text{and } i \in \{-k+1, \ldots, k-1\}.\end{array}$$

The obvious maps $X_k \to \Sigma_\infty$ define a homeomorphism

$$\varinjlim X_i \;\xrightarrow{\cong}\; \Sigma_\infty.$$

Sketch of proof.

[644] One might be tempted to say that the surface of infinite genus is the connected sum of infinitely many tori. But it is not clear that "connected sum of infinitely many tori" is actually a well-defined concept.

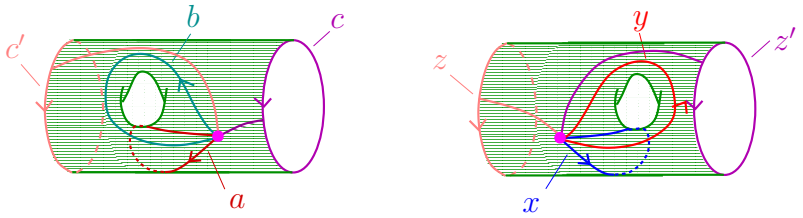


(1) This statement follows fairly easily from the Gluing-Smooth Manifolds-Proposition **??**.
(2) It follows almost immediately from the Compact-Hausdorff Proposition 2.17 (2) that for each $k \in \mathbb{Z}$ the two obvious maps $Y_k := F \times \{k\} \to \varinjlim X_i$ and $F \times \{k\} \to \Sigma_\infty$ are embeddings. Thus we can view each Y_k as a subset of $\varinjlim X_i$ and as a subset of Σ_∞. By unraveling the definitions of the topology one sees that in both cases a subset U is open if and only if the intersection with each Y_k is open. It now follows easily that the map $\varinjlim X_i \to \Sigma_\infty$ is a homeomorphism.

In both cases we leave it to the reader to fill in all the details. ■

In the following lemma we compute the fundamental group of the surface of infinite genus.

Lemma 56.11. The fundamental group of the surface of infinite genus is the free group on infinitely many generators.

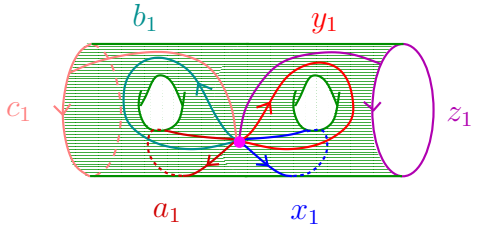


Remark. In Proposition 64.5 we will see that the fundamental group of any non-compact orientable 2-dimensional smooth manifold is a free group.

Proof. We continue with the notation from Lemma 56.10. By Lemma 56.10 (2) it suffices to show that the fundamental group of $\varinjlim X_i$ is a free group on infinitely many generators. By Lemma 55.11 we have[645]

$$\pi_1(F) \;=\; \langle a, b, c, c' \mid c = [a, b] \cdot c' \rangle \;=\; \langle x, y, z, z' \mid z = [x, y] \cdot z' \rangle$$

where the generators z, z' and c, c' correspond to the two boundary components. An induc-



tion argument, using the Seifert–van Kampen Theorem 54.4 for smooth manifolds together with Lemma 53.23 and the above presentations of $\pi_1(F)$ shows that for any $l \geq k$ we have

[645]This is indeed a consequence of Lemma 55.11, the only change is that we reversed the orientation of one of the boundary curves.

a commutative diagram

$$\begin{array}{ccc}
\pi_1(X_k) & \xrightarrow{\cong} & \left\langle \begin{matrix} x_1,y_1,\ldots,x_k,y_k \\ a_1,b_1,\ldots,a_k,b_k \end{matrix} z_k,c_k \;\middle|\; \prod_{j=1}^{k}[a_j,b_j]c_k = \prod_{j=1}^{k}[x_j,y_j]z_k \right\rangle \\
\downarrow & & \downarrow {\scriptstyle c_k\mapsto \prod_{j=k+1}^{l}[a_j,b_j]c_l,\ z_k\mapsto \prod_{j=k+1}^{l}[x_j,y_j]z_l} \\
\pi_1(X_l) & \xrightarrow{\cong} & \left\langle \begin{matrix} x_1,y_1,\ldots,x_l,y_l \\ a_1,b_1,\ldots,a_l,b_l \end{matrix} z_l,c_l \;\middle|\; \prod_{j=1}^{l}[a_j,b_j]c_l = \prod_{j=1}^{l}[x_j,y_j]z_l \right\rangle
\end{array}$$

where the left vertical map is induced by the inclusion $X_k \to X_l$. We leave the details to the energetic reader. For any $l \geq k$ we also have the following commutative diagram of

homomorphisms:

$$\begin{array}{ccc}
\left\langle \begin{matrix} x_1,y_1,\ldots,x_k,y_k \\ a_1,b_1,\ldots,a_k,b_k \end{matrix} p \right\rangle & \xrightarrow[p\mapsto \prod_{j=1}^{k}[a_j,b_j]c_k]{\cong} & \left\langle \begin{matrix} x_1,y_1,\ldots,x_k,y_k \\ a_1,b_1,\ldots,a_k,b_k \end{matrix} z_k,c_k \;\middle|\; \prod_{j=1}^{k}[a_j,b_j]c_k = \prod_{j=1}^{k}[x_j,y_j]z_k \right\rangle \\
\downarrow & & \downarrow {\scriptstyle c_k\mapsto \prod_{j=k+1}^{l}[a_j,b_j]c_l,\ z_k\mapsto \prod_{j=k+1}^{l}[x_j,y_j]z_l} \\
\left\langle \begin{matrix} x_1,y_1,\ldots,x_l,y_l \\ a_1,b_1,\ldots,a_l,b_l \end{matrix} p \right\rangle & \xrightarrow[p\mapsto \prod_{j=1}^{l}[a_j,b_j]c_l]{\cong} & \left\langle \begin{matrix} x_1,y_1,\ldots,x_l,y_l \\ a_1,b_1,\ldots,a_l,b_l \end{matrix} z_l,c_l \;\middle|\; \prod_{j=1}^{l}[a_j,b_j]c_l = \prod_{j=1}^{l}[x_j,y_j]z_l \right\rangle
\end{array}$$

The horizontal homomorphisms are in fact isomorphisms, this is for example a consequence of the Tietze transformations from page 1196.[646]

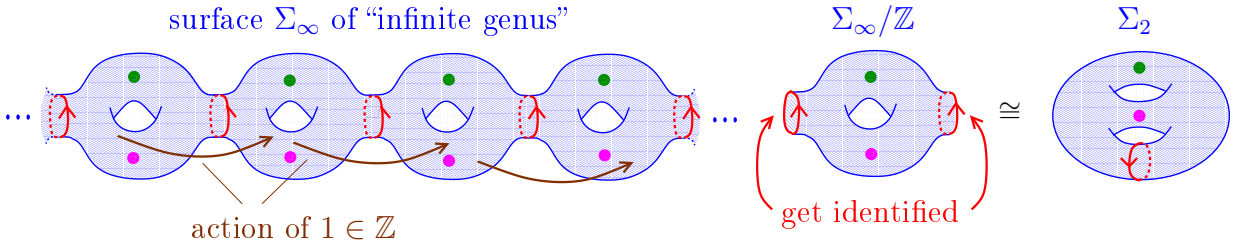
We denote by Σ_∞ the surface of infinite genus. Furthermore given any $i \in \mathbb{N}_0$ we write $U_i = X_i \setminus \partial X_i$. Note that each U_i is in fact an open subset of Σ_∞. We have

$$\pi_1(\Sigma_\infty) \underset{\text{since } \Sigma_\infty = \bigcup_{i\in\mathbb{N}_0} U_i}{=} \pi_1\big(\varinjlim U_i\big) \overset{\text{Direct Limit-}\pi_1\text{-Proposition 56.7}}{=} \varinjlim \pi_1(U_i) \underset{\text{since } \pi_1(U_i)\xrightarrow{\cong}\pi_1(X_i)}{=} \varinjlim \pi_1(X_i) \overset{\text{by the above two commutative diagrams}}{=} \varinjlim \left\langle \begin{matrix} x_1,y_1,..,x_i,y_i \\ a_1,b_1,..,a_i,b_i \end{matrix} p \right\rangle \underset{\text{see example on page 1259}}{=} \left\langle \begin{matrix} x_1,y_1,.. \\ a_1,b_1,.. \end{matrix} p \right\rangle.$$

[646] Indeed, we write $X = \{x_1,y_1,\ldots,x_m,y_m,a_1,b_1,\ldots,a_m,b_m\}$, $u = \prod_{j=1}^{m}[a_j,b_j]$, $v = \prod_{j=1}^{m}[x_j,y_j]$, $c = c_m$ and $z = z_m$, then

$$\langle X,z,c \mid uc = vz\rangle = \langle X,z,c \mid z = v^{-1}uc\rangle \xleftarrow{\cong} \langle X,c\rangle \xrightarrow{\cong} \langle X,c,p \mid p = uc\rangle = \langle X,c,p \mid X,c = u^{-1}p\rangle \xleftarrow{\cong} \langle X,p\rangle$$

where all three isomorphisms are the isomorphisms of the Tietze transformation (2). It is straightforward to see that the concatenation equals for $m = k,l$ precisely the horizontal maps in the diagram.



This concludes the proof of the lemma. ■

In the final part of this section we will see that we can actually use Lemma 56.11 to draw an interesting conclusion on fundamental groups of surfaces of *finite* genus. First we have the following lemma.

Lemma 56.12. Let $g \geq 2$. We denote by Σ_∞ the surface of infinite genus and we denote by Σ_g the surface of genus g.

(1) There exists an action of $\mathbb{Z}$ on Σ_∞ that is discrete and continuous and such that the quotient $\Sigma_\infty/\mathbb{Z}$ is homeomorphic to Σ_g.

(2) There exists a covering $p\colon \Sigma_\infty \to \Sigma_g$ of infinite degree.

Sketch of proof.

(1) We continue with the notation from page 1269 and Lemma 56.10. Let $g \in \mathbb{N}_{\geq 2}$. As before we consider

$$\Sigma_\infty := \Big(\bigcup_{i\in\mathbb{Z}} (F \times \{i\}) \Big) / \sim \quad \text{where } (\varphi_+(x), i) \sim (\varphi_-(x), i+1) \text{ for } x \in S^1 \text{ and } i \in \mathbb{Z}.$$

Given $n \in \mathbb{Z}$ and $[(x,k)] \in \Sigma_\infty$ we define $n \cdot [(x,k)] := [(x, k + (g-1)\cdot n)]$. It follows from Exercise 56.14[647] that this action is continuous and proper. Furthermore we obtain from Exercise 56.14 that the quotient $\Sigma_\infty/\mathbb{Z}$ is homeomorphic to the topological space that is given by identifying the two boundary components of

$$\Big(\bigcup_{i=0}^{g-1} (F \times \{i\}) \Big) / \sim \qquad \begin{array}{c} \text{where } (\varphi_+(x), i) \sim (\varphi_-(x), i+1) \text{ for } x \in S^1 \\ \text{and } i \in \{0, \dots, g-1\}. \end{array}$$

The experienced reader will surely be convinced that this topological space is homeomorphic to the surface of genus g. We leave it to the scrupulous reader to fill in the details.

(2) This statement follows immediately from (1) together with the Actions-Covering Proposition 48.9. ■

Using the results of this section we can prove the following proposition.

[647] It follows from the Smooth Collar Neighborhood Theorem 28.3 together with the Basics-of-Collars Lemma 28.4 that there exist open disjoint neighborhoods of the two boundary components of F, thus the extra hypothesis for Exercise 56.14 (c) is in fact satisfied.

Proposition 56.13. Let $g \geq 2$. We consider the automorphism

$$\varphi\colon \underbrace{\langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i\in\mathbb{Z}} \rangle}_{\text{free group of infinite rank}} \to \underbrace{\langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i\in\mathbb{Z}} \rangle}_{\text{same free group of infinite rank}}$$

that is induced by

$$\begin{aligned} x_{j,i} &\mapsto x_{j,i+1} \\ y_{j,i} &\mapsto y_{j,i+1}. \end{aligned}$$

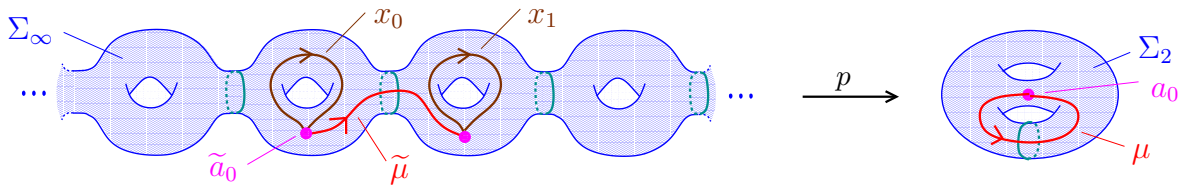
There exists an isomorphism

$$\pi_1(\Sigma_g) \cong \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i\in\mathbb{Z}} \rangle \rtimes_\varphi \mathbb{Z}.$$

Sketch of proof. We consider the surface Σ_∞ of infinite genus together with the $\mathbb{Z}$-action that is provided by Lemma 56.12 (1). By the Actions-Covering Proposition 48.9 (2) we know that the projection $p\colon \Sigma_\infty \to \Sigma_\infty/\mathbb{Z} = \Sigma_g$ is a covering.

We pick a base point $a_0 \in \Sigma_g$. Next let $\widetilde{a}_0 \in \Sigma_\infty$ be a point with $p(\widetilde{a}_0) = a_0$. It follows from Corollary 48.14 that $p_*\colon \pi_1(\Sigma_\infty, \widetilde{a}_0) \to \pi_1(\Sigma_g, a_0)$ is a monomorphism. We will use this monomorphism to view $\pi_1(\Sigma_\infty, \widetilde{a}_0)$ as a subgroup of $\pi_1(\Sigma_g, a_0)$. We pick a path $\widetilde{\mu} \in \Sigma_\infty$ from $a_0 = 0 \cdot a_0$ to $1 \cdot a_0$. We write $\mu := p \circ \widetilde{\mu}$ and we consider the isomorphism

$$\begin{aligned} \psi\colon \pi_1(\Sigma_\infty, \widetilde{a}_0) &\to \pi_1(\Sigma_\infty, \widetilde{a}_0) \\ g &\mapsto [\mu] \cdot g \cdot [\mu]^{-1}. \end{aligned}$$



Now we have the following isomorphisms:

by Lemma 56.11 we have an explicit isomorphism $\pi_1(\Sigma_\infty, \widetilde{a}_0) \cong \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i\in\mathbb{Z}} \rangle$
we leave it to the reader to verify that ψ and φ match up

$$\pi_1(\Sigma_g, a_0) \underset{\uparrow}{\overset{\cong}{\to}} \pi_1(\Sigma_\infty, \widetilde{a}_0) \rtimes_\psi \mathbb{Z} \underset{\cong}{\overset{\downarrow}{\to}} \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i\in\mathbb{Z}} \rangle \rtimes_\varphi \mathbb{Z}.$$

by the Fundamental Group-via-Actions Theorem 48.16 (2) we have an epimorphism $\gamma\colon \pi_1(\Sigma_g, a_0) \to \mathbb{Z}$ with $\gamma([\mu]) = 1$ and with kernel $\pi_1(\Sigma_\infty, \widetilde{a}_0)$
thus we obtain the isomorphism from the Semidirect Product Lemma 50.5

We have thus found the promised isomorphism. ∎

Using Proposition 56.13 we can prove the following proposition.

Proposition 56.14. Let $g \geq 2$. Every abelian subgroup of $\pi_1(\Sigma_g)$ is isomorphic to $\mathbb{Z}$.

Proof. This proposition is a pleasant application of Proposition 56.13 and Exercise 51.12. We will provide the details in Exercise 56.11. ∎

56.6. **The inverse limit of an inverse system.** For completeness' sake we also introduce the inverse limit of an inverse system, even though it will not play a role in the intermediate future.

Definition. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be a category. An inverse system in the category $\mathcal{C}$ over I is a family of objects $\{X_i\}_{i\in I}$ in $\mathcal{C}$, together with a family of

morphisms $\{f_{ji}\colon X_j \to X_i\}$ for all $i, j \in I$ with $i \leq j$[648] such that the following two conditions are satisfied:

(1) $f_{ii} = \mathrm{id}_{X_i}$ for all $i \in I$,
(2) $f_{ki} = f_{ji} \circ f_{kj}$ for all $i, j, k \in I$ with $i \leq j \leq k$.

Examples.

(A) For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}^i$ and for $i \leq j$ we denote by

$$\begin{array}{rcl} f_{ji}\colon \mathbb{Z}^j & \to & \mathbb{Z}^i \\ (x_1, \ldots, x_j) & \mapsto & (x_1, \ldots, x_i) \end{array}$$

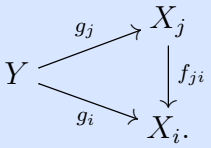
the projection onto the first i coordinates. Then $(\{\mathbb{Z}^i\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j})$ forms an inverse system in the category of groups.

(B) Let p be a prime. For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}_{p^i}$ and for $i \leq j$ we denote by

$$\begin{array}{rcl} f_{ji}\colon \mathbb{Z}_{p^j} & \to & \mathbb{Z}_{p^i} \\ n + p^j\mathbb{Z} & \mapsto & n + p^i\mathbb{Z} \end{array}$$

the natural projection. Then $(\{\mathbb{Z}_{p^i}\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j})$ forms an inverse system in the category of rings.

(C) We let $I = \mathbb{N}$, but this time we use the preorder given by divisibility, i.e. we write $k \leq l$ if and only if $k|l$. For each $k \in \mathbb{N}$ we define $X_k := \mathbb{Z}_k$ and for $k|l$ we denote by

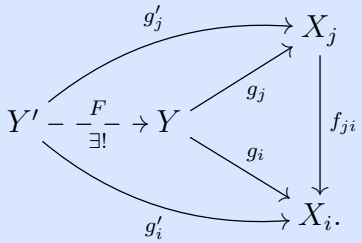


$$\begin{array}{rcl} f_{lk}\colon \mathbb{Z}_l & \to & \mathbb{Z}_k \\ n + l\mathbb{Z} & \mapsto & n + k\mathbb{Z} \end{array}$$

the natural projection. Then $(\{\mathbb{Z}_k\}_{k\in\mathbb{N}}, \{f_{lk}\}_{k|l})$ forms an inverse system in the category of rings.

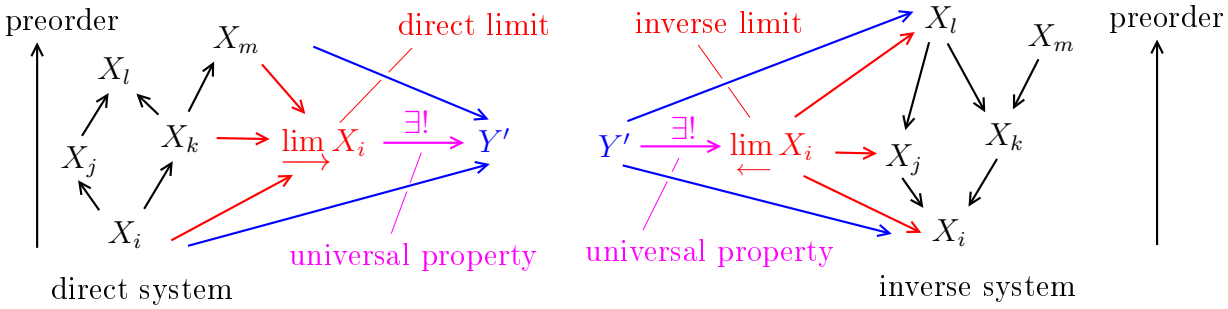
The following definition is the "mirror" image of the definition of the direct limit of a direct system.

Definition. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be a category. Furthermore suppose we are given an inverse system $(\{X_i\}_{i\in I}, \{f_{ji}\}_{i\leq j})$ in the category $\mathcal{C}$. An inverse limit[649] of the inverse system is an object Y in $\mathcal{C}$ together with morphisms $g_i\colon Y \to X_i$, $i \in I$, in the category $\mathcal{C}$ such that the following two conditions are satisfied:



(1) For all $i \leq j$ we have $f_{ji} \circ g_j = g_i\colon Y \to X_i$, i.e. for all $i \leq j$ the following diagram commutes

(2) If we are given another object Y' and morphisms $g'_i\colon Y' \to X_i$, $i \in I$, that satisfy (1), then there exists a unique morphism $F\colon Y' \to Y$ such that for all $i \leq j$ the



[648] So here for $i \leq j$ we have a morphism $X_j \to X_i$ instead of $X_i \to X_j$ in a direct system.

following diagram commutes

The "usual argument" for objects that satisfy a universal property shows that if the inverse limit exists, then it is unique in an appropriate sense. We denote the inverse limit by $\varprojlim X_i$ or sometimes by $\varprojlim_I X_i$.

In the following diagram we compare schematically the definition of the direct limit of a direct system to the inverse limit of an inverse system:[650]

Examples. In order to get an idea of how to construct inverse limits we first consider the special case that the preorder on I is trivial, in the sense that we have $i \leq j$ if and only if $i = j$.

(D) Let I be a set with the trivial preorder. Suppose that for every $i \in I$ we are given a set X_i. Together with the identity maps of the X_i this defines an inverse system

[649] Somewhat confusingly an "inverse limit" is often also called an "inductive limit" or "limit of an inverse system".

[650] The difference between a direct limit and an inverse limit is not the direction of the arrows between the X_i. In fact given a preorder "$\leq$" one could define a preorder "$\widetilde{\leq}$" via $a \widetilde{\leq} b$ if and only if $b \leq a$, hence a direct system over $(I, \leq)$ is an inverse system over $(I, \widetilde{\leq})$. The real difference is whether the X_i map to the limit, or whether the limit maps to the X_i.

over I in the category of sets. We claim that the inverse limit is given by[651]

$$\varprojlim X_i \;=\; \prod_{i\in I} X_i$$

together with the maps g_i that are given by the projection onto the i-component. Now we verify this statement. Since we only have $i \leq j$ if $i = j$ there is nothing to verify in part (1) of the definition of the inverse limit. Now suppose we are given a set Y' and maps $g_i' \colon Y' \to X_i$. Then we define

$$\begin{array}{rcl} F \colon Y' & \to & \varprojlim X_i \\ y & \mapsto & \left(\begin{array}{ccc} I & \to & \prod_{i\in I} X_i \\ i & \mapsto & g_i'(y) \end{array} \right). \end{array}$$

It is straightforward to verify that F is uniquely determined and that it has the desired property. We have thus determined the inverse limit $\varprojlim X_i$.

(E) Let I be a set with the trivial preorder and suppose that for any $i \in I$ we are given a topological space X_i. Together with the identity maps of the X_i this defines an inverse system over I in the category of topological spaces. As in (D) we define

$$\varprojlim X_i \;=\; \prod_{i\in I} X_i$$

and each map g_i is again given by the projection onto the i-component.

To conclude that we have found an inverse limit in the category of topological spaces we still have to equip $\prod_{i\in I} X_i$ with a topology which has the following two properties:

(i) the maps $g_i \colon \prod_{i\in I} X_i \to X_i$ are continuous,

(ii) given a topological space Y' and continuous maps $g_i' \colon Y' \to X_i$ the map F, defined as in (D), is continuous.[652]

We set

$$\mathcal{B} \;:=\; \left\{ \prod_{i\in I} U_i \;\subset\; \prod_{i\in I} X_i \;\middle|\; \begin{array}{ll} (1) & \text{each } U_i \text{ is open in } X_i \text{ and} \\ (2) & \text{there exist only finitely many } i\text{'s with } U_i \neq X_i \end{array} \right\}.$$

---

[651] Recall that the product $\prod_{i\in I} X_i$ is defined as the set of all maps $f \colon I \to \bigsqcup_{i\in I} X_i$ with the property that $f(i) \in X_i$ for all $i \in I$. Such a map f is often written as $(f(i))_{i\in I}$ and often we refer to $f(i)$ as the *i-component* of f. Furthermore we refer to the map

$$\begin{array}{rcl} \prod_{i\in I} X_i & \to & X_i \\ f & \mapsto & f(i) \end{array}$$

as the *projection onto the i-component*. Note that if the X_i's are groups, rings or modules, then the product inherits this algebraic structure by component-wise multiplication and addition.

[652] On the product $\prod_{i\in I} X_i$ we could also consider the topology $\mathcal{T}$ that is generated by all sets of the form $\prod_{i\in I} U_i$ with U_i open in X_i. This might be a more "natural" topology on $\prod_{i\in I} X_i$. But with this topology $\mathcal{T}$ the map F does not necessarily have to be continuous. The problem is that $\mathcal{T}$ has "too many" open sets.

It is straightforward to verify that $\mathcal{B}$ has the basis property that we introduced on page 132. We equip $\prod_{i\in I} X_i$ with the topology generated by this basis and we refer to this topology as the *product topology*.[653] Now we need to verify that we found the correct topology on the direct limit.

(i) It follows immediately from the definitions that the maps g_i are continuous with respect to the product topology.

(ii) Suppose we are given Y and g_i' as above. We denote by F the map defined as above. We claim that F is continuous. By the Subbasis-Continuity Proposition 2.9 it suffices to verify that the preimage of any set in $\mathcal{B}$ is open. So let $\prod_{i\in I} U_i$ be a set in $\mathcal{B}$. Then

$$F^{-1}\Big(\prod_{i\in I} U_i\Big) = \bigcap_{i\in I} (g_i')^{-1}(U_i) = \bigcap_{U_i\neq X_i} \underbrace{(g_i')^{-1}(U_i)}_{\text{open in } Y\text{'}} = \begin{array}{c}\text{intersection of finitely}\\ \text{many open subsets of } Y'.\end{array}$$

This concludes the proof that F is continuous.

Now we can prove fairly easily that inverse limits exist in many categories that are of interest to us.

Proposition 56.15. (Inverse Limit Existence Proposition) The inverse limit of any inverse system exists in the following categories:

(0) the category *Set* of sets,
(1) the category *Top* of topological spaces,
(2) the category *Group* of groups,
(3) the category *TopGr* of topological groups,
(4) the category *AbGroup* of abelian groups,
(5) the category *Ring* of rings,
(6) the category of R-modules, where R is a commutative ring.

Furthermore, the direct limits of (0),...,(6) are "coherent". For example if $\{X_i\}_{i\in I}$ is a direct system of topological groups, then the direct limit is the direct system of the corresponding topological spaces together together with an appropriate group structure.

We will see that the proof of the Inverse Limit Existence Proposition 56.15 is a relatively straightforward generalization of the examples (D) and (E) above.

Proof. Let $(I,\leq)$ be a preordered set and let $\mathcal{C}$ be one of the seven given categories. Furthermore let $(\{X_i\}_{i\in I}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system in the category $\mathcal{C}$. We define

$$\varprojlim X_i := \big\{(x_i)_{i\in I} \in \prod_{i\in I} X_i \,\big|\, f_{ji}(x_j) = x_i \text{ for all } i \leq j\big\}.$$

Furthermore we denote by $g_i\colon \varprojlim X_i \to X_i$ the natural projections. It follows immediately from the definitions that for any $i \leq j$ we have $f_{ji}\circ g_j = g_i$. Furthermore, given an object Y' and morphisms $g_i'\colon Y' \to X_i$, $i\in I$ which satisfy the condition $f_{ji}\circ g_j' = g_i'$ for all $i\in I$

[653] If the index set I is finite, i.e. if we consider the product of finitely many topological spaces, then this definition of the product topology agrees with the definition given on page 224.

we define

$$\begin{array}{rcl} F\colon Y' & \to & \varprojlim X_i \\ y & \mapsto & \left(\begin{array}{ccc} I & \to & \prod\limits_{i\in I} X_i \\ i & \mapsto & g_i'(y) \end{array} \right). \end{array}$$

It is straightforward to verify that $F(Y')$ lies in $\varprojlim X_i$ and that F is the unique map with the desired property. This shows that the inverse limit exists in the category of sets.[654]

For the remaining six categories we will use the same definition of the direct limit as a set and the same maps, but we now have to verify that we have objects and morphisms in the given category.

(1) Suppose that we work in the category of topological spaces. We equip $\prod\limits_{i\in I} X_i$ with the product topology that we defined in Example (E) above. We equip $\varprojlim X_i$ with the subspace topology. The same argument as in Example (E) shows that the maps g_i and F are continuous.

(2) In the category of groups we view $\prod\limits_{i\in I} X_i$ as a group via component-wise multiplication. Since the f_{ij} are group homomorphisms we see that $\varprojlim X_i$ is a subgroup of $\prod\limits_{i\in I} X_i$. It is straightforward to verify that the above maps are all morphisms in the category of groups.

(3) We equip the set $\varprojlim X_i$ with the topological structure and the group structure as in the above statements (1) and (2). It follows from Lemma 5.39 that this turns $\varprojlim X_i$ into a topological group, which turns out to be the inverse limit of the inverse system of topological groups.

(4),(5),(6) These categories are dealt with the same way as (2).

For all seven categories we have now provided an inverse limit. Since we always equipped the same set with different structures we see that the direct limits are coherent. ■

Remark. We consider the important special case that the preordered set $(I, \leq) = (\mathbb{N}, \leq)$. Furthermore let

$$(\{X_n\}_{n\in\mathbb{N}}, \{f_{nm}\colon X_n \to X_m\}_{m\leq n})$$

[654]Now we will see that we can use the "same" inverse limit for all the categories, this is very different from the construction of the direct limit for the same categories. There, in the proof of the Direct Limit Existence Proposition 56.1, we had to use several different construction.

be an inverse system over $(\mathbb{N}, \leq)$ in any of the above seven categories. Given $n \in \mathbb{N}_{\geq 2}$ we write $g_n := f_{n,n-1} \colon X_n \to X_{n-1}$. We have

$$\begin{aligned} \varprojlim X_i &= \big\{(x_1, x_2, x_3, \dots) \mid x_n \in X_n \text{ for all } n \in \mathbb{N} \text{ and } f_{nm}(x_n) = x_m \text{ for all } m \leq n\big\} \\ &= \big\{(x_1, x_2, x_3, \dots) \mid x_n \in X_n \text{ for all } n \in \mathbb{N} \text{ and } g_n(x_n) = x_{n-1} \text{ for all } n \in \mathbb{N}_{\geq 2}\big\} \end{aligned}$$

$\uparrow$ follows from $f_{nm} = f_{n,n-1} \circ \cdots \circ f_{m+1,m} = g_n \circ \cdots \circ g_{m+1}$

$$= \text{all infinite sequences of the form } \begin{array}{ccc} \vdots & & \vdots \\ \downarrow & & \downarrow \\ x_3 & \in & X_3 \\ \downarrow & & \downarrow g_3 \\ x_2 & \in & X_2 \\ \downarrow & & \downarrow g_2 \\ x_1 & \in & X_1 \end{array}$$

This discussion shows that we can view of elements in the inverse limit as "upward going sequences".

Now we return to our initial examples of inverse systems and their inverse limits.

Examples.

(A) It follows quite easily from the previous remark that

$$\varprojlim_{n \in \mathbb{N}} \mathbb{Z}^n = \{(x_1, x_2, x_3, \dots) \mid x_n \in \mathbb{Z}\} \cong \mathbb{Z}^{\mathbb{N}}.$$

Note that this is an uncountable group. Recall that on page 1258 we had determined that

$$\varinjlim \mathbb{Z}^i = \mathbb{Z}^{(\mathbb{N})} = \{(x_1, x_2, \dots) \mid x_i \in \mathbb{Z} \text{ but only finitely many } x_i \text{ are non-zero}\}$$

which is a countable group.[655] Thus we see that in this particular case the inverse limit is "much larger" than the direct limit.[656]

(B) Let p be a prime. The inverse limit $\widehat{\mathbb{Z}}_p := \varprojlim \mathbb{Z}_{p^i}$ of the rings $\mathbb{Z}_{p^i} = \mathbb{Z}/p^i\mathbb{Z}$ is called the *ring of the p-adic numbers*.[657] The p-adic numbers play a very prominent role in many branches of pure mathematics.

(C) The inverse limit $\widehat{\mathbb{Z}} := \varprojlim \mathbb{Z}_n$ of the rings $\mathbb{Z}_n$, $n \in \mathbb{N}$, with the preorder on $\mathbb{N}$ defined by the divisibility relation $k|l$, is called the *ring of the profinite integers*. Using the Chinese Remainder Theorem one can show that

$$\widehat{\mathbb{Z}} \cong \prod_{\text{prime } p} \widehat{\mathbb{Z}}_p.$$

[655] Why is $\mathbb{Z}^{(\mathbb{N})}$ countable?

[656] Note though that we are comparing limits of different system, first of a direct system and then of an inverse system.

[657] In number theory one often uses a different convention, namely one writes explicitly $\mathbb{Z}/p\mathbb{Z}$ for the quotient ring and one denotes the p-adic numbers by $\mathbb{Z}_p$. If the expression "$\mathbb{Z}_p$" appears in a paper or a book it is a good idea to check the convention used by the author.

Now we continue with three examples that we had not considered yet.

(D) We let $(I, \leq) = (\mathbb{N}, \leq)$. Given $i \in \mathbb{N}$ we set $X_i := \mathbb{N}$ and for $i \leq j$ we define

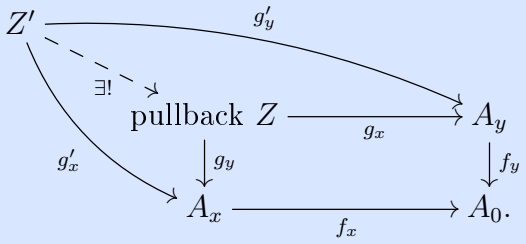
$$\begin{aligned} f_{ji} \colon X_j = \mathbb{N} &\to X_i = \mathbb{N} \\ n &\mapsto n + (j - i). \end{aligned}$$

Then $(\{X_i = \mathbb{N}\}_{i \in \mathbb{N}}, \{f_{ji}\}_{i \leq j})$ forms an inverse system in the category of sets. In Exercise 56.10 we will see that in this case the inverse limit is the empty set.

(E) Let X be a topological space. We denote by K the set of all compact subsets of X. We consider K with the preorder given by inclusion, i.e. we have $A \leq B$ if $A \subseteq B$. Given $A \in K$ we define $X_A := X \setminus A$. Furthermore given $A \leq B$ we denote by[658] $f_{AB} \colon \pi_0(X_B) \to \pi_0(X_A)$ the map induced by the inclusion $X_B \to X_A$. It is straightforward to verify that the sets $\{\pi_0(X_A)\}_{A \in K}$, together with the inclusion induced maps f_{AB} for $A \leq B$ define an inverse system in the category of sets. The elements of $\text{ends}(X) := \varprojlim \pi_0(X_A)$ are called the *ends of* X. In Exercise 56.13 we will determine the number of ends of $X = \mathbb{R}^n$.

(F) Given a topological space Y we denote by $C(Y, \mathbb{R})$ the abelian group of all continuous functions on Y. Note that for each subset $W \subset Y$ we have a homomorphism $C(Y, \mathbb{R}) \to C(W, \mathbb{R})$ given by $f \mapsto f|_W$, i.e. given by restricting a function on Y to a function on W.

Let X be a topological space and let $\{U_i\}_{i \in \mathbb{N}}$ be a sequence of open subsets such that for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$ and such that $\bigcup_{i \in \mathbb{N}} U_i = X$. Then the groups $\{C(U_i, \mathbb{R})\}_{i \in \mathbb{N}}$ together with the restriction maps form an inverse system. We leave it to the reader to verify that the restriction maps from X to the U_i gives rise to an isomorphism



$$C(X, \mathbb{R}) \to \varprojlim C(U_i, \mathbb{R}).$$

Definition. Let $(\{0, x, y\}, \leq)$ be the push-pull set as defined on page 1256, i.e. the preordered set with the non-trivial relations $0 \leq x$ and $0 \leq y$, and let $\mathcal{C}$ be a category. An inverse system in the category $\mathcal{C}$ over $(\{0, x, y\}, \leq)$ consists of three objects A_0, A_x, A_y, the identity morphisms $\text{id}_{A_0}, \text{id}_{A_x}, \text{id}_{A_y}$ and morphisms $f_x \colon A_x \to A_0$ and $f_y \colon A_y \to A_0$. We refer to such a system as a pullback system and often we arrange the morphisms in a diagram as follows

$$\begin{array}{ccc} & & A_y \\ & & \downarrow{\scriptstyle f_y} \\ A_x & \xrightarrow[f_x]{} & A_0. \end{array}$$

If the inverse limit of such a pullback system exists, then we refer to it as the pullback of the pullback system. The defining property of the pullback Z can be summarized in the following diagram

[658] Recall that on page 167, given a topological space Y we defined $\pi_0(Y)$ as the set of path-components of Y. A map $f \colon Y \to Z$ between two topological spaces induces a map $f_* \colon \pi_0(Y) \to \pi_0(Z)$ in an obvious way.

The following lemma deals with the pullback in the category of topological spaces.

Lemma 56.16. (Topological-Pullback Lemma) Let $p\colon X \to B$ be a map of topological spaces, let C be a topological space and let $f\colon C \to B$ be a map.

(1) In the category of topological spaces the pullback of the pullback system

$$\begin{array}{ccc} & & X \\ & & \downarrow{\scriptstyle p} \\ C & \xrightarrow[f]{} & B \end{array} \quad \text{is given by} \quad \begin{array}{ccc} f^*X := \{(c,x) \in C \times X \mid f(c) = p(x)\} & \xrightarrow{(c,x)\mapsto x} & X \\ {\scriptstyle (c,x)\mapsto c}\downarrow & & \downarrow{\scriptstyle p} \\ C & \xrightarrow[f]{} & B. \end{array}$$

Often the pullback is denoted by f^*X.

(2) If X and C are connected, then f^*X is also connected.

(3) Let $p\colon X \to B$ be a covering.

(a) The pullback $q\colon f^*X \to C$ is also a covering.

(b) If B is connected, then

$$\deg(q\colon f^*X \to C) \;=\; \deg(p\colon X \to B).$$

(c) Let $c \in C$. We write $b = f(c)$ and we pick[659] $x \in X$ such that $p(x) = b$. The following equality holds:

$$q_*(\pi_1(f^*X, (c,x))) \;=\; f_*^{-1}(p_*(\pi_1(X,x))) \;\subset\; \pi_1(C,c).$$

Proof.

(1) This statement follows quite easily from the definitions or alternatively from the proof of the Inverse Limit Existence Proposition 56.15.

(2) We will prove this statement in Exercise 56.17.

(3) Let $p\colon X \to B$ be a covering. We write $Z := f^*X$ and $z := (c,x)$. Finally we denote by $q\colon f^*X \to C$ the map given by $(c,x) \mapsto c$.

(a) Suppose $V \subset B$ is uniformly covered. In Exercise 56.16 we will verify that $f^{-1}(V)$ is uniformly covered. Since $f^{-1}(V)$ is open we see that $q\colon Z \to C$ is a covering.

(b) Since B is connected it makes sense to speak of the degree of p. For any $c \in C$ we have a bijection

$$q^{-1}(c) \;=\; \{(c,x) \in C \times X \mid f(c) = p(x)\} \xrightarrow{\text{bijection}} p^{-1}(f(c)) \;=\; \deg(p).$$

This shows that the degree of q equals the degree of p.

[659] Recall that covering maps are in particular surjective, in particular such x exists.

(c) We need to show that $q_*(\pi_1(Z,z)) = f_*^{-1}(\pi_1(X,x))$. We show the two inclusions "$\subset$" and "$\supset$" separately.

"$\subset$" Let $\widetilde{f}\colon Z \to X$ be the map given by $(c,x) \to x$. By construction we have $f \circ q = \widetilde{f} \circ p$. But this implies immediately that $f_*(q_*(\pi_1(Z,z))$ is contained in $p_*(\pi_1(X,x))$.

"$\supset$" Let $\gamma\colon [0,1] \to C$ be a loop in (C,c) with $[f \circ \gamma] = f_*([\gamma]) \in p_*(\pi_1(X,x))$. We write $g := f \circ \gamma$. Let $\widetilde{g}\colon [0,1] \to X$ be the lift with $\widetilde{g}(0) = x$. Since $[g] \in p_*(\pi_1(X,x))$ we obtain from Lemma 48.15 (1) that $\widetilde{g}$ is actually a loop. Thus the map $\alpha\colon [0,1] \to C \times X$ that is given by $t \mapsto (\gamma(t), \widetilde{g}(t))$ is a loop. By construction the loop takes values in Z and evidently we have $q_*([\alpha]) = [\gamma]$. This shows that $[\gamma] \in q_*(\pi_1(Z,z))$. ∎

We conclude this section on inverse limits with the following lemma.

Lemma 56.17. Let $(I,\leq)$ be a preordered set and let $(\{X_i\}_{i\in I}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system of topological spaces.

(1) If all the X_i's are Hausdorff, then the inverse limit $\varprojlim X_i$ is a closed subset of $\prod_{i\in I} X_i$.

(2) If all the X_i's are compact and Hausdorff, then the inverse limit $\varprojlim X_i$ is also compact.[660]

Example. Let p be a prime. The abelian group $\widehat{\mathbb{Z}}_p$ is the inverse limit of finite, hence compact groups. It follows from Proposition 56.18 that $\widehat{\mathbb{Z}}_p$ is also a compact topological group. On the other hand $\widehat{\mathbb{Z}}_p$ is infinite,[661] which shows that the topology on $\widehat{\mathbb{Z}}_p$ is *not* the discrete topology.

Proof. Let $(I,\leq)$ be a preordered set and let $(\{X_i\}_{i\in I}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system of topological spaces.

(1) We suppose that all the X_i are Hausdorff. Given $i \in I$ we denote by $p_i\colon \prod_{j\in J} X_j \to X_i$ the projection and we denote by $D_i = \{(x,x) \mid x \in X_i\} \subset X_i \times X_i$ the diagonal. By Exercise 5.23 the hypothesis that X_i is Hausdorff implies that the diagonal D_i is a closed subset of $X_i \times X_i$. By the proof of the Inverse Limit Existence Proposition 56.15 we have

$$\begin{aligned}\varprojlim X_i &:= \Big\{(x_i)_{i\in I} \in \prod_{i\in I} X_i \,\Big|\, f_{lk}(x_l) = x_k \text{ for all } k \leq l\Big\} \\ &= \bigcap_{k\leq l} \Big\{x \in \prod_{i\in I} X_i \,\Big|\, \underbrace{((f_{lk}\circ p_l) \times p_k)}_{\substack{(f_{lk}\circ p_l)\times p_k \text{ is a map} \\ \prod_{i\in I} X_i \to X_k \times X_k}}(x) \in D_k\Big\} = \bigcap_{k\leq l} \underbrace{((f_{lk}\circ p_l)\times p_k)^{-1}(D_k)}_{\text{closed since } D_k \text{ closed}}.\end{aligned}$$

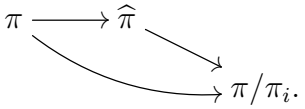
Thus we see that $\varprojlim X_i$ is the intersection of closed subsets of $\prod_{i\in I} X_i$, hence $\varprojlim X_i$ itself is a closed subset.

[660] Note that this is very different from the situation of the direct limit. The direct limit of topological spaces is not necessarily compact, for example the direct limit of the direct system $[0,n]$, $n \in \mathbb{N}$ is given by the non-compact space $\bigcup_{n\in\mathbb{N}} [0,n] = [0,\infty)$.

[661] In fact $\widehat{\mathbb{Z}}_p$ is uncountable (why?).

(2) Now we suppose that all the X_i are Hausdorff and compact. We obtain from Tychonoff's Theorem 5.9 that $\prod_{i\in I} X_i$ is compact. Together with (1) we see that $\varprojlim X_i$ is a closed subset of a compact space. Thus it follows from the Compact-Closed Lemma 1.21 (1) that $\varprojlim X_i$ is also compact. ■

56.7. **The profinite completion of a group.** Note that we can view any group as a topological group by equipping it with the discrete topology. With this topology a group is compact if and only if it is finite. Furthermore any homomorphism of groups equipped with the discrete topology is also a morphism in the category $\mathcal{TopGr}$ of topological groups.



Proposition 56.18. Let $(I, \leq)$ be a preordered set and let $(\{G_i\}_{i\in I}, \{f_{ji}\colon G_j \to G_i\}_{i\leq j})$ be an inverse system of finite groups. Then the inverse limit $\varprojlim G_i$ exists in the category of topological groups and it is a compact topological group.

Proof. It follows from the Inverse Limit Existence Proposition 56.15 that the inverse limit $\varprojlim G_i$ exists in the category of topological groups. Since all the G_i's are finite, in particular compact, it follows from Lemma 56.17 (2) that the inverse limit $\varprojlim G_i$ is also compact. ■

Now let π be a group. We consider the set of all finite index normal subgroups $\{\pi_i\}_{i\in I}$. We equip the index set I with the preorder defined by the convention that $i \leq j$ if and only if $\pi_j \subset \pi_i$.[662] Given $i \leq j$ we denote by $\varphi_{ji}\colon \pi/\pi_j \to \pi/\pi_i$ the natural projection. Then $(\{\pi/\pi_i\}_{i\in I}, \{\varphi_{ji}\colon \pi/\pi_j \to \pi/\pi_i\}_{i\leq j})$ forms an inverse system. We refer to

$$\widehat{\pi} := \varprojlim \pi/\pi_i$$

as the *profinite completion of* π. By Proposition 56.18 the profinite completion $\widehat{\pi}$ is a compact topological group. It follows immediately from the definition of an inverse limit that there exists a unique homomorphism $\pi \to \widehat{\pi}$ such that for any i the following diagram commutes:

Examples.

(1) The profinite completion $\widehat{\mathbb{Z}}$ of the group $\mathbb{Z}$ equals precisely the profinite integers that we had encountered on page 1279.
(2) The profinite completion of a finite group G is the group itself, i.e. $\widehat{G} = G$.[663]
(3) Let $G = \mathbb{Q}$. This group has no proper subgroups of finite index.[664] It follows immediately from the definitions that $\widehat{\mathbb{Q}} = \{0\}$.

Now let $\varphi\colon A \to B$ be a group homomorphism. We denote by $\{B_i\}_{i\in I}$ the finite index normal subgroups of B. For $B_j \subset B_i$ we denote again by $p_{ji}\colon B/B_j \to B/B_i$ the projection . For every $i \in I$ the preimage $\varphi^{-1}(B_i)$ is a finite index normal subgroup of A.[665] Now we define $\psi_i\colon \widehat{A} \to A/\varphi^{-1}(B_i) \xrightarrow{\varphi} B/B_i$. Note that ψ_i is continuous since the first map is

[662] Note that we wrote $\pi_j \subset \pi_i$ instead of $\pi_i \subset \pi_j$.
[663] Why is that?
[664] Why not?
[665] Why is it a finite index subgroup?

continuous by definition and the second map is a map between two topological spaces that are equipped with the discrete topology. It follows immediately from the definitions that for $B_j \subset B_i$ we have $p_{ji} \circ \psi_j = \psi_i$. It now follows from the definition of the inverse limit in the category of topological groups that there exists a unique continuous homomorphism $\widehat{\varphi}\colon \widehat{A} \to \widehat{B}$ such that for any i the following diagram commutes

$$\begin{array}{ccc} \widehat{A} & \xrightarrow{\widehat{\varphi}} & \widehat{B} \\ & \searrow^{\psi_i} & \downarrow \\ & & B/B_i. \end{array}$$

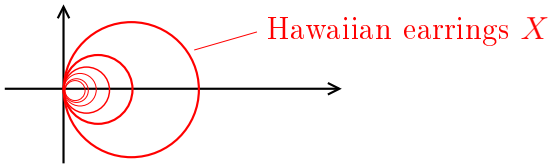
It follows easily from the definitions and Proposition 56.18 that the maps

together with the maps

$$\begin{array}{rcl} A & \mapsto & \widehat{A} \\ \mathrm{Mor}(A,B) & \to & \mathrm{Mor}(\widehat{A},\widehat{B}) \\ (\varphi\colon A \to B) & \mapsto & (\widehat{\varphi}\colon \widehat{A} \to \widehat{B}) \end{array}$$

define a functor from the category of groups to the category of compact topological groups.

Exercises for Chapter 56.

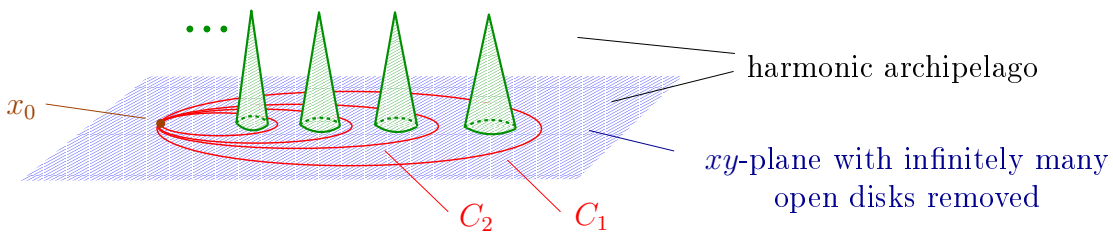


Exercise 56.1. We consider the following subset of $\mathbb{R}^2$:

$$X := \bigcup_{n\in\mathbb{N}} \text{circle of radius } \tfrac{1}{n} \text{ around } (\tfrac{1}{n},0) = \bigcup_{n\in\mathbb{N}} \{(x,y)\in\mathbb{R}^2 \mid (x-\tfrac{1}{n})^2 + y^2 = \tfrac{1}{n^2}\}.$$

This subset, equipped with the subspace topology is colloquially referred to as the *Hawaiian earrings*, see the figure below for an illustration.

(a) Let $A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Show that X is homeomorphic to $[0,1]/A$.
Remark. We encountered the topological space $[0,1]/A$ in Exercise 5.37.
(b) Show that X is compact.
(c) Is X homeomorphic to the wedge of countably infinitely many circles?
(d) Show that $\pi_1(X)$ is infinitely generated.
(e) Even better than (d): Show that $\pi_1(X)$ is uncountably generated, i.e. show that there is no countable generating set for $\pi_1(X)$.



The combination of (b) and (d) implies, perhaps somewhat surprisingly, that there exist compact spaces whose fundamental groups are infinitely generated.
Remark. The precise determination of $\pi_1(X)$ is actually rather delicate, we refer to **[MoM1986]** and **[Smit1992]** for details. In particular, despite appearances, it is shown in **[Smit1992]** that $\pi_1(X)$ is not a free group.

Exercise 56.2. For $n \in \mathbb{N}$ let C_n be the circle in $\mathbb{R}^2 \times \{0\}$ of radius $\frac{1}{2n}$ with center $(\frac{1}{n},0)$. The *harmonic archipelago* H is the topological space that obtained from $\mathbb{R}^2$ as follows: For

each $n \in \mathbb{N}$ we delete an open disk between C_n and C_{n+1} and we glue on a cone such that the z-coordinate of the cone equals 1. We refer to the figure below for an illustration.

(a) Give a precise description of the harmonic archipelago H.
Remark. You might want to skip this exercise, unless you are inclined to super-rigorous mathematics.
(b) Show that the harmonic archipelago H is non-compact.
(c) Let $x_0 = (0,0)$ be the origin. Show that for each n the inclusion induced map $\pi_1(C_n, x_0) \to \pi_1(H, x_0)$ is a monomorphism.
(d) As in Exercise 56.1 we refer to $X := \bigcup_{n\in\mathbb{N}} C_n$ as the Hawaiian earrings. Show that the inclusion induced map $\pi_1(X, x_0) \to \pi_1(H, x_0)$ is not a monomorphism.
(e) Is $\pi_1(H, x_0)$ countable or uncountable?

Exercise 56.3.

(a) Given $k \leq l \in \mathbb{N}$ we consider the homomorphism

$$\begin{array}{rccc} \varphi_{kl}\colon & \mathbb{Z} & \to & \mathbb{Z} \\ & n & \mapsto & \frac{l!}{k!} \cdot n. \end{array}$$

These homomorphisms define a direct system $(\{\mathbb{Z}\}_{k\in\mathbb{Z}}, \{\varphi_{kl}\}_{k\leq l})$ in the category of abelian groups. Show that the corresponding direct limit $\varinjlim \mathbb{Z}$ is isomorphic to $(\mathbb{Q}, +)$.
(b) Provide a direct system $(\{G\}_{i\in\mathbb{N}}, \{\varphi_i\colon G_i \to G_j\}_{i\leq j})$ consisting of finitely generated abelian groups such that the direct limit is isomorphic to $\mathbb{Z}[\frac{1}{2}]$.
(c) Provide a direct system $(\{G\}_{i\in\mathbb{N}}, \{\varphi_i\colon G_i \to G_j\}_{i\leq j})$ consisting of finitely generated abelian groups such that the direct limit is isomorphic to $\mathbb{Q}^2$.

Exercise 56.4. Let $f_n\colon X_n \to X_{n+1}$ be a sequence of morphisms in any category. Suppose there exists an $N \in \mathbb{N}$ such that all f_n for $n \geq N$ are isomorphisms. Show that $\varinjlim X_n$ exists and show that it is naturally isomorphic to X_N, more precisely, show that a direct limit is given by $\varinjlim X_n := X_N$ and show that the maps

$$\begin{array}{rccll} f_{N-1} \circ \cdots \circ f_{n+1} \circ f_n\colon & X_n & \to & X_N & \text{if } n \leq N, \\ (f_n \circ \cdots \circ f_{N+1} \circ f_N)^{-1}\colon & X_n & \to & X_n & \text{if } n > N \end{array}$$

define a direct limit.

Exercise 56.5. Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i\in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. We define

$$\varinjlim X_i \;=\; X \;:=\; \bigcup_{i\in I} X_i,$$

where the topology on $X = \bigcup_{i\in I} X_i$ is given by the rule that $U \subset X$ is open if and only if $U \cap X_i$ is open for all $i \in I$. Furthermore we denote by $g_j \colon X_j \to X = \bigcup_{i\in I} X_i, j \in \mathbb{N}$ the obvious inclusion maps. Show that $\varinjlim X_i$ together with the maps g_j is the direct limit of the direct system in the category of topological spaces.

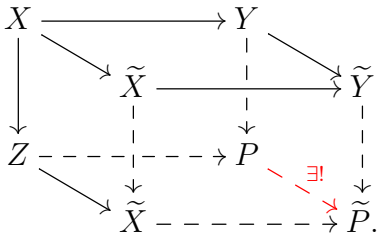
Exercise 56.6. Let $\{X_i\}_{i\in\mathbb{N}}$ be a family of topological spaces. Suppose that for each $i \in \mathbb{N}$ we are given an injective map $f_i \colon X_i \to X_{i+1}$.

(a) Show the map $X_i \to \varinjlim X_i$ is not necessarily an embedding.

(b) Suppose that each $f_i \colon X_i \to X_{i+1}$ is an embedding. Show that in this case each map $X_i \to \varinjlim X_i$ is in fact an embedding.

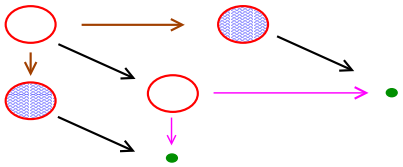
Exercise 56.7.

(a) For $i \in \mathbb{N}$ we define $F_i = \langle x_i, x_{i+1}\rangle$. For $i \in \mathbb{N}$ we denote by $g_i \colon F_i \to F_{i+1}$ the homomorphism that is given by $g_i(x_i) = e, g_i(x_{i+1}) = x_{i+1}$. Furthermore for $i < j$ we define $f_i \colon F_i \to F_j$ to be the homomorphism $g_{j-1} \circ \cdots \circ g_{i+1} \circ g_i$. What is the direct limit $\varinjlim F_i$ in the category of groups?



(b) Given $k \in \mathbb{N}$ we define $X_k = \mathbb{N}$ to be the topological space where the open sets are $\{1, \dots, k\}, \{k+1\}, \{k+2\}, \dots$. For $k \le l$ we denote by $f_{kl} \colon X_k \to X_l$ the identity map. (Note that with the choice of our topologies on X_k and X_l this map is in fact continuous). What is the direct limit $\varinjlim X_k$ in the category of topological spaces?

Remark. as a set the direct limit is again $\mathbb{N}$, but what is the topology?



Exercise 56.8. Suppose we are given two pushouts

$$\begin{array}{ccc} X & \longrightarrow & Y \\ \downarrow & & \downarrow \\ Z & \dashrightarrow & P \end{array} \quad \text{and} \quad \begin{array}{ccc} \widetilde{X} & \longrightarrow & \widetilde{Y} \\ \downarrow & & \downarrow \\ \widetilde{Z} & \dashrightarrow & \widetilde{P}. \end{array}$$

Furthermore suppose we are given a commutative diagram

An example for such a situation is sketched in the figure below.

(a) Show that there exists a unique map $P \to \widetilde{P}$ which makes the cube commute.

(b) Suppose that the maps $X \to \widetilde{X}$, $Y \to \widetilde{Y}$ and $Z \to \widetilde{Z}$ are homotopy equivalences. Does it follows that the map $P \to \widetilde{P}$ is a homotopy equivalence?

Exercise 56.9. Proof the Direct Limit Stabilization Lemma 56.2. It is best to prove it using the definition of direct limits instead of using any of the above explicit descriptions of direct limits.

Exercise 56.10. We let $(I, \leq) = (\mathbb{N}, \leq)$. Given $i \in \mathbb{N}$ we set $X_i := \mathbb{N}$ and for $i \leq j$ we define

$$\begin{array}{rccc} f_{ji}\colon X_j = \mathbb{N} & \to & X_i = \mathbb{N} \\ n & \mapsto & n + (j - i). \end{array}$$

Then $(\{X_i = \mathbb{N}\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j})$ forms an inverse system in the category of sets. Show that the inverse limit is the empty set.

Exercise 56.11. Let $g \geq 2$. We denote by Σ_g the surface of genus g. Show that every abelian subgroup of $\pi_1(\Sigma_g)$ is isomorphic to $\mathbb{Z}$.
Hint. Make use of Proposition 56.13 and Exercise 51.12.

Exercise 56.12. Let $g \in \mathbb{N}_{\geq 2}$. Use Proposition 56.13 to show that the fundamental group of the surface of genus g is torsion-free.

Exercise 56.13. Let X be a topological space. We denote by $\mathcal{K}$ the set of all compact subsets of X. We consider $\mathcal{K}$ with the preorder given by inclusion, i.e. given $A, B \in \mathcal{K}$ we have $A \leq B$ if $A \subseteq B$. Given $A \in \mathcal{K}$ we define[666] $X_A := \pi_0(X \setminus A)$. Furthermore given $A \leq B$ we denote by $f_{AB}\colon \pi_0(X_B) \to \pi_0(X_A)$ the map induced by the inclusion $X_B \to X_A$. It follows immediately from the discussion on page 200 that the sets $\{\pi_0(X_A)\}_{A\in\mathcal{K}}$, together with the inclusion induced maps f_{AB} for $A \leq B$ define an inverse system in the category of sets. The elements of $\varprojlim \pi_0(X_A)$ are called the *ends of* X.

(a) Let *Top* be the category of topological spaces and let *Set* be the category of sets. Show that

$$X \mapsto \varprojlim \pi_0(X_A)$$

gives rise to a covariant functor from *Top* to *Set*.
(b) Show that for a topological space X the cardinality of $\varprojlim \pi_0(X_A)$, viewed as an element in $\mathbb{N}_0 \cup \{\infty\}$, equals the number of ends of M as defined in Exercise 2.27.
(c) Let $n \in \mathbb{N}_0$. Determine the number of ends of $X = \mathbb{R}^n$.
(d) For each $k \in \mathbb{N}_0$ give an example of a connected 1-dimensional CW-complex X with precisely k ends.

Exercise 56.14. Let X be a topological space, let A and B be two subsets of X and let $f\colon A \to B$ be a homeomorphism. We define

$$\widetilde{X} := \Big(\bigcup_{i\in\mathbb{Z}} X \times \{i\}\Big) / (a, i) \sim (f(a), i - 1) \quad \text{for } a \in A \text{ and } i \in \mathbb{Z}.$$

We consider the action of $\mathbb{Z}$ on $\widetilde{X}$ that is given by $n\cdot[(x, i)] := [(x, i+n)]$ for $(x, i) \in X \times \{i\}$.

(a) Show that this action is continuous.
(b) We write $X(f) = X/\!\sim$ where $a \sim f(a)$ for $a \in A$. Show that the maps

$$\begin{array}{rccc} \Phi\colon X(f) & \to & \widetilde{X}/\mathbb{Z} \\ [x] & \mapsto & [(x, 0)] \end{array} \quad \text{and} \quad \begin{array}{rccc} \Psi\colon \widetilde{X}/\mathbb{Z} & \to & X(f) \\ [(x, i)] & \mapsto & [x] \end{array}$$

are continuous and inverses of one another. (This implies of course that both maps are homeomorphisms.)

[666] Recall that by the definition on page 167, given a topological space Y we had denoted $\pi_0(Y)$ by the set of path-components of X.

(c) Suppose that there exist disjoint open neighborhoods U of A and V of B. Show that the action is discrete.

Exercise 56.15. We consider the profinite integers, i.e. the inverse limit $\widehat{\mathbb{Z}} := \varprojlim \mathbb{Z}_n$ of the rings $\mathbb{Z}_n$, $n \in \mathbb{N}$, with the preorder on $\mathbb{N}$ defined by the divisibility relation $k|l$. Does there exist an epimorphism $\widehat{\mathbb{Z}} \to \mathbb{Z}$ of groups?

Exercise 56.16. Show that the pullback $f^*X \to C$ of a covering $p\colon X \to B$ under a map $f\colon C \to B$ is again a covering.

Exercise 56.17. Let $f^*X \to C$ be the pullback of a map $p\colon X \to B$ and a map $f\colon C \to B$. Show that if X and C are connected, then f^*X is also connected.

Exercise 56.18. Let $1 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 1$ be a short exact sequence of groups. Furthermore let $g\colon Z \to C$ be a group homomorphism. Show that there exists a commutative diagram of group homomorphisms of the form below such that the top horizontal sequence is also exact:

$$\begin{array}{ccccccccc} 1 & \longrightarrow & A & \xrightarrow{\widetilde{\alpha}} & Y & \xrightarrow{\widetilde{\beta}} & Z & \longrightarrow & 1 \\ & & \downarrow{=} & & \downarrow{f} & & \downarrow{g} & & \\ 1 & \longrightarrow & A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & \longrightarrow & 1. \end{array}$$

Exercise 56.19.

(a) We consider the inverse system $(X_i)_{i\in\mathbb{N}}$ where $X_i = \mathbb{Z}$ and where for each $i \geq j$ the map $X_i \to X_j$ is given by multiplication by 2^{i+j}. Determine $\varprojlim X_i$ in the category of abelian groups.

(b) Now we work in the category of sets. Show that there exists an inverse system $(\{X_i\}_{i\in\mathbb{N}}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ of non-empty sets such that $\varprojlim X_i = \varnothing$.

Remark. In Exercise 56.20 we will see that the inverse limit of an inverse system of *finite non-empty sets* is in fact non-empty.

Exercise 56.20. In this exercise we consider the category of topological space. Let $(\{X_i\}_{i\in\mathbb{N}}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system of topological spaces that are non-empty, Hausdorff and compact.

(a) For each $j \in \mathbb{N}$ we set

$$Z_j := \{(x_i)_{i\in\mathbb{N}} \mid \text{ for all } i \leq j \text{ we have } x_i = f_{ji}(x_j)\} \subset \prod_{i\in\mathbb{N}} X_i.$$

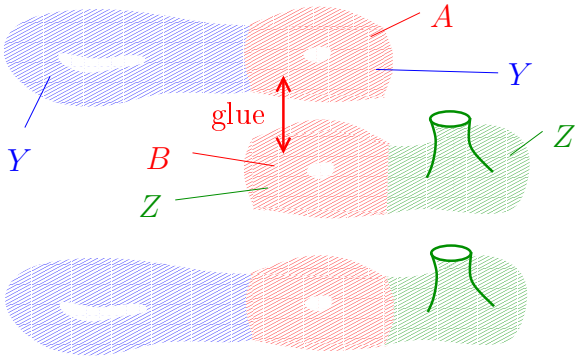
Show that Z_j is closed and non-empty.
Hint. You might want to consider Lemma 56.17 (1).

(b) Show that for any $i, j \in \mathbb{N}$ we have $Z_i \cap Z_j \neq \varnothing$.

(c) Apply Tychonoff's Theorem 5.9, together with Exercise 1.29, to conclude that $\varprojlim X_i \neq \varnothing$.

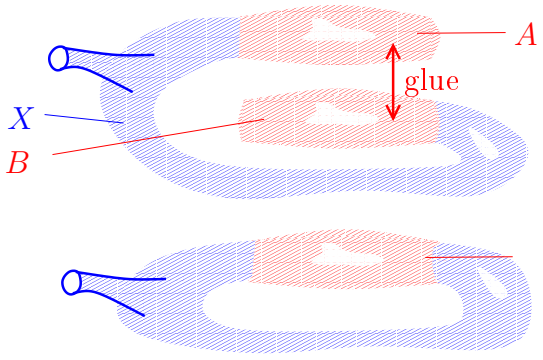
Remark. We can apply this statement in particular to an inverse system of finite non-empty sets, viewed as topological spaces by equipping each of the finite sets with the discrete topology. Evidently a finite discrete space is Hausdorff and compact.

Exercise 56.21. Let I be preordered set, let $\{f_i \colon A_i \to A_j\}_{i \leq j}$ be a direct system in the category of abelian groups and let $\{g_i \colon B_i \to B_j\}_{j \leq i}$ be an inverse system in the category of abelian groups. Suppose that for each $i \in I$ we are given a bilinear map $\varphi_i \colon A_i \times B_i \to \mathbb{Z}$ such that for any $i \leq j$, and $a \in A_i$ and $b \in B_j$ we have $\varphi_i(a_i, g_j(b_j)) = \varphi_j(f_i(a_i), b_j)$. Define an "interesting" bilinear map



$$\varinjlim A_i \times \varprojlim B_i \to \mathbb{Z}.$$

57. The HNN-Seifert–van Kampen Theorem



One of our main goals at the moment is to calculate fundamental groups of interesting topological spaces. As we have discovered, one of the most powerful tools is the Seifert–van Kampen Theorem 54.1.

In light of Exercise 5.38 (c) we can say, modulo technical details, that the Seifert–van Kampen Theorem 54.1 allows us to calculate the fundamental group of a topological space $X = Y \cup_f Z$ that is obtained from gluing two path-connected topological spaces Y and Z along path-connected open subsets $A \subset Y$ and $B \subset Z$. This situation is illustrated in the figure below, to the left.

Sometimes one is given the situation that is shown in the figure below, to the right. Namely we are given a path-connected topological space X and we glue two disjoint path-connected open subsets A and B together. In this chapter we will prove the HNN-Seifert–van Kampen Theorem which will allow us to calculate the fundamental group in the latter situation.

$\pi_1(Y \cup_f Z) = \pi_1(Y) *_{\pi_1(A)} \pi_1(Z)$

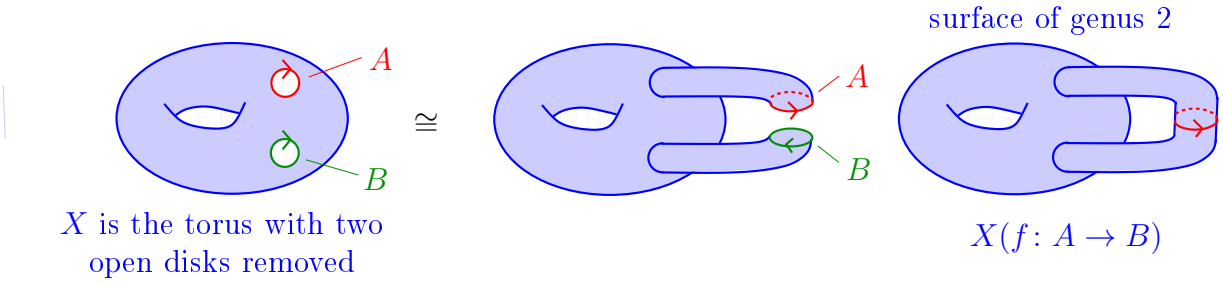
$\pi_1 = ???$

We start out with the following notation.

Notation. Let X be a topological space, let A and B be two subsets of X and let $f\colon A \to B$ be a homeomorphism. We write

$$X(f) \;:=\; X(f\colon A \to B) \;:=\; X/\!\sim \qquad \text{where } f(a) \sim a \text{ for } a \in A.$$

Examples.



(1) Let X be the torus with two open disks removed. We denote by A and B the two boundary components and we endow them with the orientation coming from a fixed orientation of the torus. Let $f\colon A \to B$ be an orientation-reversing diffeomorphism. Then one sees that $X(f\colon A \to B)$ is diffeomorphic[667] to the surface of genus 2. This statement is illustrated in the figure below.[668]

(2) Let Y be a topological space and let $f\colon Y \to Y$ be a homeomorphism. We consider $X = Y \times [0,1]$. Furthermore, by an abuse of notation, we denote by $f\colon Y \times \{0\} \to Y \times \{1\}$ also the map defined by $f(y,0) = (f(y),1)$. It follows immediately from the definitions that

$$X(f) \;=\; (Y \times [0,1])(f) \;=\; (Y \times [0,1])/\!\sim \;=\; \mathrm{Tor}(X,f),$$

[667] Note that by Lemma **??** we know that $X(f\colon A \to B)$ is indeed a smooth manifold.

[668] What topological space do we obtain if f is chosen to be orientation-preserving?

where $\mathrm{Tor}(X, f)$ denotes the mapping torus that we introduced on page 467.

Our goal now is to determine $\pi_1(X(f))$ in terms of the fundamental groups of X, A and the induced map $f_*\colon \pi_1(A) \to \pi_1(B)$. To formulate the Seifert–van Kampen Theorem 54.1 we needed to introduce the notion of an amalgamated product of groups. So it does perhaps now come as a surprise that we need a new construction from group theory to formulate the desired result.

Definition. Let π and Γ be two groups and let $\alpha, \beta\colon \Gamma \to \pi$ be two homomorphisms. We refer to

$$\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \;:=\; (\pi * \langle t \rangle) \,/\, \langle\langle \{\alpha(g)t\beta(g)^{-1}t^{-1}\}_{g\in\Gamma} \rangle\rangle$$

as the HNN-extension corresponding to (π, α, β).[669]

Example. Let π be a group and let Γ be the trivial group. It follows immediately from the definitions that the corresponding HNN-extension is the free product $\pi * \langle t \rangle$.

The following lemma summarizes some basic properties of HNN-extensions. It says in particular that a semidirect product is a special case of an HNN-extension.

Lemma 57.1.

(1) Let $\pi = \Gamma$. Furthermore let $\alpha\colon \pi \to \pi$ and $\beta\colon \pi \to \pi$ be isomorphisms. We write $\varphi = \beta \circ \alpha^{-1}\colon \pi \to \pi$. In this setting the map

$$\begin{array}{rcl} \Phi\colon \pi \rtimes_\varphi \mathbb{Z} & \to & \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\ (g, n) & \mapsto & g \cdot t^{-n} \end{array}$$

is an isomorphism.

(2) Let $\pi = \langle x_1, \dots, x_k \mid r_1, \dots, r_l \rangle$ be a finitely presented group and let $g_1, \dots, g_m$ is a generating set for Γ. A presentation for the HNN-extension of (π, α, β) is given by

$$\langle x_1, \dots, x_k, t \mid r_1, \dots, r_l, \alpha(g_i) = t\beta(g_i)t^{-1} \text{ for } i = 1, \dots, m \rangle.$$

(3) Let π and Γ be two groups and let $\alpha, \beta\colon \Gamma \to \pi$ be two homomorphisms. Then there exists an epimorphism

$$\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \;\to\; \mathbb{Z}$$

that is uniquely determined by $g \mapsto 0$ if $g \in \pi$ and $t^n \mapsto n$.

Sketch of proof.

[669] The concept of such a group was introduced by Graham Higman, Bernhard Neumann and Hannah Neumann [**HNN1950**] in 1950, whence the name.

(1) We first verify that the given map is indeed a homomorphism. Let (g, m) and (h, n) be two elements in $\pi \rtimes_\varphi \mathbb{Z}$. First we assume that $m \geq 0$. Then the following equalities hold in $\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle$:

$$\begin{array}{c} \text{since } \alpha \text{ is an isomorphism we can write} \\ h = \alpha(\alpha^{-1}(h)) = t\beta(\alpha^{-1}(h))t^{-1} = t\varphi(h)t^{-1} = t \cdot t\varphi(\varphi(h))t^{-1} \cdot t^{-1} = \cdots = t^m\varphi^m(h)t^{-m} \end{array}$$

$$\begin{array}{rcll} \Phi(g,m) \cdot \Phi(h,n) = gt^{-m} \cdot ht^{-n} & \overset{\downarrow}{=} & gt^{-m} \cdot t^m\varphi^m(h)t^{-m} \cdot t^{-n} & = g\varphi^m(h)t^{-m-n} \\ & = & \Phi(g\varphi^m(h), m+n) & = \Phi((g,m)(h,n)). \\ & & & \uparrow \\ & & & \text{definition of product structure on } \pi \rtimes_\varphi \mathbb{Z} \end{array}$$

If $m < 0$ then a very similar calculation, using that β is an isomorphism, shows again that $\Phi(g, m) \cdot \Phi(h, n) = \Phi((g, m)(h, n))$. This shows that Φ is indeed a homomorphism. By Lemma 51.13 there exists a unique homomorphism

$$\Psi \colon \pi * \langle t \rangle \ \to \ \pi \rtimes \mathbb{Z}$$

with $\Psi(g) = (g, 0)$ for every $g \in \pi$ and with $\Psi(t) = (0, 1)$. Using Lemma 53.4 and using an elementary calculation one can easily show that Ψ descends to a map $\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \to \pi \rtimes \mathbb{Z}$. Since $\Phi \circ \Psi$ and $\Psi \circ \Phi$ are the identity on the generating sets π and t we see that both homomorphisms are the identity. In particular Φ is an isomorphism.

(2) This time we apply Lemma 53.4 twice to obtain the desired isomorphism and its inverse.

(3) This statement is once again an immediate consequence of Lemma 53.4. ■

The following proposition is an analogue of the Amalgamated Product-Monomorphism Proposition 53.24.

Proposition 57.2. (HNN-Extension Monomorphism Proposition) Let π and Γ be two groups and let $\alpha, \beta \colon \Gamma \to \pi$ be two homomorphisms. If α and β are monomorphisms, then the obvious inclusion map

$$\begin{array}{ccl} \pi & \to & \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \ := \ (\pi * \langle t \rangle) \,/\, \langle\langle \{\alpha(g)t\beta(g)^{-1}t^{-1}\}_{g \in \Gamma} \rangle\rangle \\ h & \mapsto & h \end{array}$$

is also a monomorphism.

Proof. The proposition is proved in [**Ser1980**, p. 45]. Alternatively the proposition follows from the Normal Form Theorem for HNN-extensions which is formulated and proved in [**LyS1977**, Theorem IV.2.1] or alternatively in [**CgRR2008**, Satz 6.3] and [**Sti1993**, Chapter 9.2]. ■

Now we return to topological spaces. The following theorem can be considered a sibling of the Seifert–van Kampen Theorem 54.1.

Theorem 57.3. (HNN-Seifert–van Kampen Theorem) Suppose we are in one of the following two settings:

(1) We are given a path-connected topological space X, two open disjoint subsets A and B of X and a homeomorphism $f \colon A \to B$.

(2) We are given a path-connected smooth manifold X, two distinct components A and B of ∂X and a homeomorphism $f \colon A \to B$.

We pick a base point $x_0 \in A$ and we pick a path γ in X from x_0 to $f(x_0)$. Furthermore we write $\Gamma = \pi_1(A, x_0)$. Finally we denote by

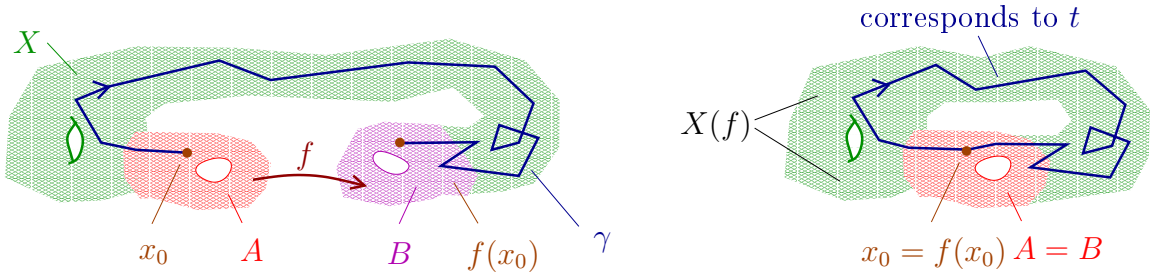
$$\alpha\colon \Gamma = \pi_1(A, x_0) \to \pi_1(X, x_0)$$

the inclusion induced map and we denote by

$$\beta\colon \Gamma = \pi_1(A, x_0) \xrightarrow{f_*} \pi_1(B, f(x_0)) \to \pi_1(X, f(x_0)) \xrightarrow{\gamma_*} \pi_1(X, x_0)$$

the concatenation of the maps induced by f, the inclusion and the base point change isomorphism from the Change-of-Base Point Proposition 47.10, using the path γ. Then there exists an isomorphism

$$\Phi\colon \pi_1(X(f), x_0) \xrightarrow{\cong} \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle$$



which has the following two properties:

(1) The diagram

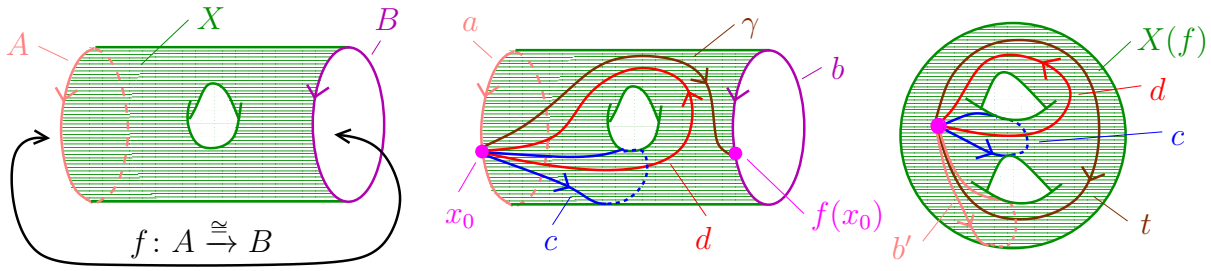
$$\begin{array}{ccc} & \pi_1(X, x_0) & \\ \swarrow & & \searrow \\ \pi_1(X(f), x_0) & \xrightarrow{\Phi} & \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \end{array}$$

with the obvious diagonal maps commutes.

(2) The closed loop in $X(f)$ defined by γ corresponds under the isomorphism Φ to t.

Remark. The HNN-Seifert–van Kampen Theorem 57.3 is a frequently used tool in the calculation of fundamental groups of topological spaces. The popularity of the result is in contrast to the sparsity of proofs in the literature. A sketch of an outline of a proof is given in [**ScW1979**]. A much more general statement is proved in [**Bou2007**, Proposition IV.5.5 on p. 431].

Example. As on page 1290 we consider the surface X that is given by removing two open disks from a torus. We refer to the two boundary components as A and B. We equip A and B with the orientations given in the figure below. We pick a diffeomorphism $f\colon A \to B$ that preserves the orientation. As discussed on page 1290, the resulting topological space $X(f)$ is homeomorphic to the surface of genus two.



We pick a base point $x_0 \in A$. We pick a loop a in (A, x_0), we pick loops c, d in (X, x_0), a path γ in X from x to $f(x)$ and a loop b in $(B, f(x))$ as indicated in the figure below. Finally we write $\widetilde{b} = \gamma * b * \overline{\gamma}$. By Lemma 55.11 and as in the proof of Lemma 56.11 we have an isomorphism

$$\pi_1(X, x_0) \xrightarrow{\cong} \langle c, d, a, \widetilde{b} \mid a = [c, d] \cdot \widetilde{b} \rangle.$$

We write $\Gamma = \pi_1(A, x_0)$. Note that $\Gamma = \langle a \rangle$ and $\alpha(a) = a$ and $\beta(a) = \widetilde{b}$. We see that

$$\begin{array}{ccccc} \pi_1(X(f), x_0) & \underset{\text{Theorem 57.3 (2)}}{\cong} & \langle \pi_1(X), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle & \underset{\text{Lemma 57.1}}{=} & \langle c, d, a, \widetilde{b}, t \mid a = [c,d] \cdot \widetilde{b}, a = t\widetilde{b}t^{-1} \rangle \\ & \underset{\text{Tietze transformations}}{=} & \langle c, d, \widetilde{b}, t \mid [c,d] \cdot \widetilde{b} = t\widetilde{b}t^{-1} \rangle & = & \langle c, d, \widetilde{b}, t \mid \underbrace{[c,d] \cdot \widetilde{b}t\widetilde{b}^{-1}t^{-1}}_{=[c,d][\widetilde{b},t]} \rangle. \end{array}$$

Thus we have now obtained the same presentation that we had already obtained in the Fundamental Group-of-Surfaces Proposition 54.5.

In the proof of Theorem 57.3 (1) we will need one extra piece of notation and one more lemma.

Notation. Let π and Γ be groups and let $\alpha, \beta\colon \Gamma \to \pi$ be homomorphisms. Given $i \in \mathbb{Z}$ we write $\pi_i := \pi$ and $\Gamma_i := \Gamma$. We write[670]

$$\ldots \pi_{-2} \underset{\Gamma_{-1}}{*} \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \underset{\Gamma_2}{*} \pi_2 \ldots := \varinjlim \Big(\underbrace{\pi_{-i} \underset{\Gamma_{-i+1}}{*} \ldots \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \ldots \underset{\Gamma_i}{*} \pi_i}_{\text{iterated amalgamated product defined by } \alpha \text{ and } \beta} \Big).$$

By a slight abuse of language we refer to this group as an infinite amalgamated product. By the universal property of the direct limit there exists an automorphism Ξ of this infinite amalgamated product that shifts all indices by one to the right.

Lemma 57.4. With the above notation there exists a well-defined map

$$\begin{array}{rcl} \Big(\ldots \pi_{-2} \underset{\Gamma_{-1}}{*} \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \underset{\Gamma_2}{*} \pi_2 \ldots \Big) \rtimes_\Xi \mathbb{Z} & \xrightarrow{\cong} & \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\ (g_i, n) & \mapsto & gt^{-i} \cdot t^n, \quad \text{where } g_i \in \pi_i \end{array}$$

which is an isomorphism.

Example. If α and β are isomorphisms, then it follows easily from the Amalgamated Product Lemma 53.22 (3) that the "infinite amalgamated product" is isomorphic to π. We see that in this special case the statement of Lemma 57.4 is basically the same as the statement of Lemma 57.1 (1).

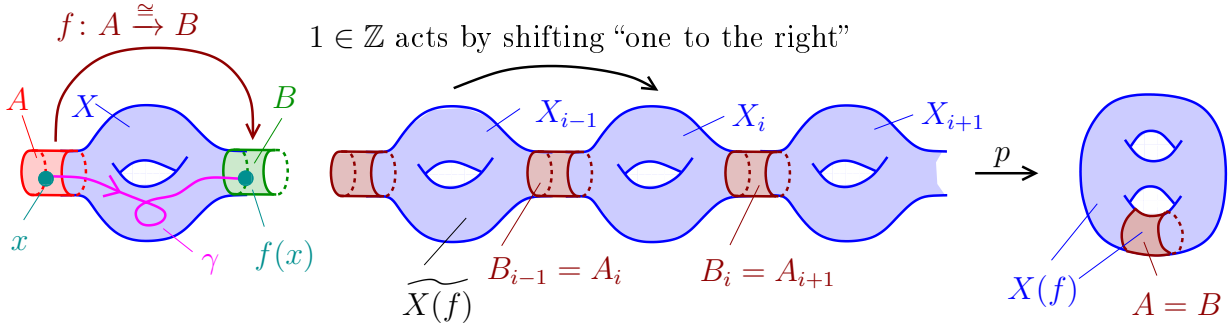
Sketch of proof of Lemma 57.4. It follows easily from the universal property of the direct limit and of the amalgamated product that there exists a well-defined map

$$\begin{array}{rcl} \ldots \pi_{-2} \underset{\Gamma_{-1}}{*} \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \underset{\Gamma_2}{*} \pi_2 \ldots & \to & \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\ g_i & \mapsto & gt^{-i}, \quad \text{where } g_i = g \in \pi_i = \pi. \end{array}$$

[670] By the Amalgamated Product Lemma 53.22 (4) we can form the iterated amalgamated product without having to worry about parentheses.

A straightforward calculation as in the proof of Lemma 57.1 (1) shows that we get an induced map on the semidirect product. This shows that the map given in the lemma actually makes sense. It remains to show that the map is an isomorphism. Note that using Lemma 53.4 one can easily show that there exists a well-defined homomorphism from right to left which is an inverse to our given map. We leave it to the reader to fill in the details. ■

Proof of Theorem 57.3 (1). [671] Let X be a path-connected topological space, let A and B be two open disjoint path-connected subsets of X and let $f\colon A \to B$ be a homeomorphism. We pick a base point $x \in A$ and we pick a path γ in X from x to $f(x)$. Furthermore we define



$$\widetilde{X(f)} \;:=\; \Big(\bigcup_{i\in\mathbb{Z}} X \times \{i\}\Big) \,/\, (a,i) \sim (f(a), i-1) \qquad \text{for } a \in A \text{ and } i \in \mathbb{Z}.$$

We equip $\widetilde{X(f)}$ with the base point $\widetilde{x}$ which is represented by $(x,0)$. There is an obvious action of $\mathbb{Z}$ on $\widetilde{X(f)}$ given by $n \cdot [(P,i)] := [(P,i+n)]$ for $(P,i) \in X \times \{i\}$. Since A and B are open and disjoint we can apply Exercise 56.14. We obtain that this action is discrete and continuous and that the map

$$\begin{array}{rccc} \Phi\colon & X(f) & \to & \widetilde{X(f)}/\mathbb{Z} \\ & [x] & \mapsto & [(x,0)] \end{array}$$

is a homeomorphism.

For $i \in \mathbb{Z}$ we now write $X_i := X \times \{i\}$, $A_i := A \times \{i\}$, $B_i := B \times \{i\}$ and $x_i := \{x\} \times \{i\}$. Furthermore we write $\pi_i := \pi_1(X_i, x_i)$ and $\Gamma_i = \pi_1(A_i, x_i)$. We refer to the figure below for an illustration.

Claim. Given any $i \in \mathbb{Z}$ we consider the homomorphism

$$\pi_i \;=\; \pi_1(X_i, x_i) \;\underset{\uparrow}{\longrightarrow}\; \pi_1(\widetilde{X(f)}, x_i) \;\underset{\uparrow}{\longrightarrow}\; \pi_1(\widetilde{X(f)}, \widetilde{x}).$$

induced by the inclusion $X_i \to \widetilde{X(f)}$

induced by the Change-of-Base Point Proposition 47.10 (1) where we use i translates of the path γ to connect x_i to $\widetilde{x} = x_0$

[671] As we saw on pages 1291 and in Lemma 57.1 (1), we can view Theorem 57.3 as a generalization of the Mapping Torus-π_1-Proposition 50.6. In fact the subsequent proof is partly modelled on the proof of the Mapping Torus-π_1-Proposition 50.6.

These homomorphisms induce an isomorphism

$$\dots \pi_{-2} \underset{\Gamma_{-1}}{*} \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \underset{\Gamma_2}{*} \pi_2 \dots \xrightarrow{\cong} \pi_1(\widetilde{X(f)}, \widetilde{x}).$$

Here given $i \in \mathbb{Z}$ the maps in the amalgamated product are defined as follows:

$$\overbrace{\pi_1(X_{i-1}, x_{i-1})}^{=\pi_{i-1}} \xleftarrow[\uparrow]{\gamma_*} \pi_1(X_{i-1}, f(x_{i-1})) \xleftarrow[\uparrow]{} \pi_1(B_{i-1}, f(x_i)) \xleftarrow{f_*} \overbrace{\pi_1(A_i, x_i)}^{=\Gamma_i} \xrightarrow[\uparrow]{} \overbrace{\pi_i(X_i, x_i)}^{=\pi_i}.$$

given by the Change-of-Base Point

induced by the inclusion $B_{i-1} \to X_{i-1}$

Proposition 47.10 (1)

induced by the inclusion $A_i \to X_i$

Proof. To prove the claim we need to introduce one more gadget. Namely, given $n \in \mathbb{N}$ we write

$$\widetilde{Y}_n := \Big(\bigcup_{i=-n}^{n} X_i \Big) / (a, i) \sim (f(a), i-1) \quad \text{for } a \in A, i \in \{-n+1, \dots, n\}.$$

It follows from the Seifert–van Kampen Theorem 54.1, applied iteratively $2n$ times, that

$$\pi_1\big(\widetilde{Y}_n, \widetilde{x}\big) \xleftarrow{\cong} \pi_{-n} \underset{\Gamma_{-n+1}}{*} \pi_{-n+1} \dots \pi_{n-1} \underset{\Gamma_n}{*} \pi_n.$$

Now we see that

$$\pi_1\big(\widetilde{X(f)}, \widetilde{x}\big) = \pi_1\big(\varinjlim \widetilde{Y}_n, \widetilde{x}\big) \xleftarrow[\uparrow]{\cong} \varinjlim \pi_1\big(\widetilde{Y}_n, \widetilde{x}\big) \xleftarrow[\uparrow]{\cong} \dots \pi_{-2} \underset{\Gamma_{-1}}{*} \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \underset{\Gamma_2}{*} \pi_2 \dots$$

since A, B are open in X we can apply the Direct Limit-π_1-Proposition 56.7 (3)

by the above calculation and the definition of the right hand side ⊞

In summary we obtain isomorphisms

$$\begin{array}{ccc} \pi_1(X(f), x) & \cong & \pi_1\big(\widetilde{X(f)}/\mathbb{Z}, [\widetilde{x}]\big) \\ & \cong & \pi_1(\widetilde{X(f)}, \widetilde{x}) \rtimes \mathbb{Z} \\ & \xrightarrow{\cong} & \langle \pi_1(X(f), x), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle. \end{array}$$

above homeomorphism

by the Fundamental Group-via-Actions Theorem 48.16 (2) and and the Semidirect Product Lemma 50.5, here the automorphism Θ is given by conjugation by $[\gamma] \in \pi_1(X(f), x)$

Corollary 48.14

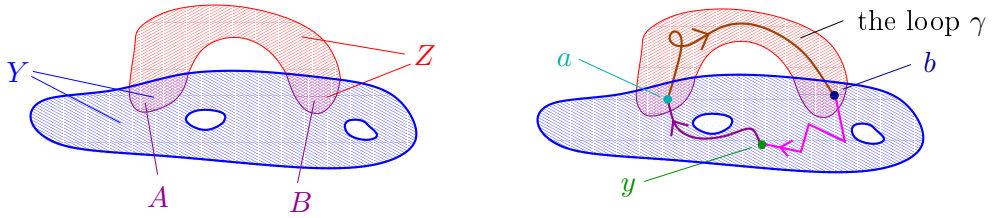
here, as on page 1294, we denote by Ξ the automorphism of the infinite amalgamated product that "shifts every term by one to the right", isomorphism is then given by the above claim and the verification that under this isomorphism the automorphisms Θ and Ξ match up

Lemma 57.4

We leave it to the reader to verify that the given isomorphism has all the properties that were promised. ■

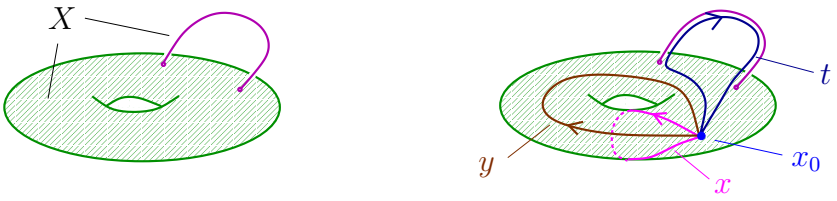
Sketch of the proof of Theorem 57.3 (2). The proof of Theorem 57.3 (2) is basically the same as the proof of Theorem 57.3 (1), we just need to replace the Seifert–van Kampen Theorem 54.1 by the Seifert–van Kampen Theorem 54.4 for smooth manifolds. We leave it to the reader to fill in the details and to make the necessary changes to the proof. ■

In many situations the following corollary to the HNN-Seifert–van Kampen Theorem 57.3 is quite useful.



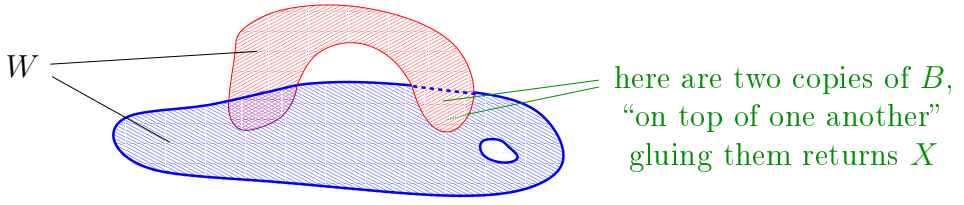
Corollary 57.5. Let X be a topological space. We suppose that it can be written as a union $X = Y \cup Z$ such that the following conditions are satisfied:

(1) Y and Z are open subsets,
(2) Y is path-connected,
(3) Z is simply connected,
(4) $Y \cap Z$ consists of two simply connected path components A and B, each of which is open in X.



Let y be a point in Y and let γ be the concatenation of a path in Y from y to a point $a \in A$, a path in Z from a to a point $b \in B$ and a path in Y from b to y. Then the map

$$\pi_1(Y, y) * \langle t \rangle \ \to \ \pi_1(X, y)$$



that is given by the inclusion induced map $\pi_1(Y, y) \to \pi_1(X, y)$ and given by $t \mapsto [\gamma]$ is an isomorphism.

Example. We consider the topological space X that is obtained from "gluing an interval" to the torus. Using the notation from the figure below one can show quite easily, using Corollary 57.5 that $\pi_1(X, x_0) \cong \langle x, y, t \,|\, [x, y] \rangle \cong \mathbb{Z}^2 * \langle t \rangle$. We will work out the details of this example in Exercise 57.1.

Proof. Let Z' be a disjoint copy of Z (e.g. we could set $Z' = Z \times \{0\}$). We consider $W = (Y \sqcup Z')/a \sim a'$ where we identify each point $a \in A$ with the corresponding point in Z'. We denote by B' the copy of B in Z' and thus also the copy in W. Thus we see

that B and its doppelgänger B' are contained in W. We denote by $f \colon B' \to B$ the obvious

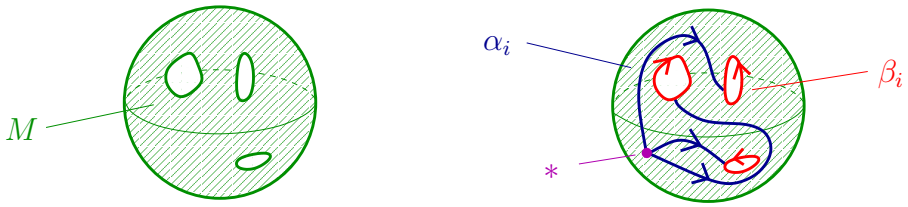
homeomorphism. We obtain the following isomorphisms:[672]

$$\pi_1(X,y) \underset{\text{by Lemma 5.36 the obvious map } X \to W(f) \text{ is a homeomorphism}}{\uparrow\cong} \pi_1(W(f),y) \underset{\text{by the HNN-Seifert–van Kampen Theorem 57.3 and since } B \text{ is simply connected}}{\downarrow\cong} \pi_1(W,y)*\langle t\rangle \underset{\text{Seifert–van Kampen Theorem 52.2}}{\uparrow\cong} (\pi_1(Y,y)*_{\pi_1(A,y)}\pi_1(Z',y))*\langle t\rangle \underset{\text{since } A \text{ and } Z' \text{ are simply connected}}{\uparrow=} \pi_1(Y,y)*\langle t\rangle.$$

One can easily verify that this is precisely the map in the statement of the corollary. ■

We conclude this chapter with the following technical lemma which we will need once at a later occasion.

Lemma 57.6. Let $n \in \mathbb{N}$ and let M be the 2-sphere with n open disks removed. We enumerate the boundary components by $C_1, \dots, C_n$. For $i = 1, \dots, n$ we pick a path $\beta_i \colon [0,1] \to C_i$ that goes once around C_i. We pick a base point $* \in M \setminus \partial M$. We pick paths $\alpha_1, \dots, \alpha_n \colon [0,1] \to M$ with the following properties:



(1) each α_i is a smooth embedding,
(2) each α_i is a path from $*$ to the point $\beta_i(0)$,
(3) for each i we have $\alpha_i([0,1)) \subset M \setminus \partial M$,
(4) the images of the paths only intersect at $*$.

For any $j \in \{1, \dots, n\}$ the homomorphism

$$\begin{array}{rcl} \langle y_1, \dots, y_{j-1}, y_{j+1}, \dots, y_n\rangle & \to & \pi_1(M,*) \\ y_i & \mapsto & [\alpha_i * \beta_i * \overline{\alpha_i}] \end{array}$$

that is uniquely determined by

is an isomorphism.

Remark.

(1) This proposition should ring a bell, it sounds quite like Lemma 55.11. The difference is that in Lemma 55.11 we only said that there exist certain paths β_i such that the given map is an isomorphism. The above lemma gives a more precise statement what type of paths work.
(2) One might think that perhaps one can use any old paths α_i to obtain a basis for the free group $\pi_1(M,*)$. But as we will see in Exercise 57.6, this is not the case.

We conclude this chapter with a sketch of a proof of Lemma 57.6. Perhaps the most friendly words that can be uttered regarding the proof are that the proof shows that it can be quite hard to write down rigorous arguments once one leaves the friendly word of submanifolds and instead tries to deal with more general subsets.

[672] It follows from our hypothesis that A, Y, Z are open in X that in the settings of the HNN-Seifert–van Kampen Theorem 57.3 and the Seifert–van Kampen Theorem 52.2 we do in fact deal with open subsets.

Sketch of a proof. Without loss of generality we can assume that $j = n$. We consider $N := M \setminus \alpha_n([0,1])$. This is an open subset of the smooth manifold M, thus N itself is a smooth manifold. Furthermore by Exercise **??** we know that the inclusion $M \setminus \alpha_n([0,1]) \to M$ is a homotopy equivalence.[673] For $i = 1, \dots, n-1$ we write $X_i := \alpha_i((0,1]) \subset N$. It follows from (1) and the Smooth Embedding Theorem 24.10 (1) that $X = X_1 \cup \dots \cup X_{n-1}$ is a submanifold of N. By the Tubular Neighborhood Theorem **??** we can pick a tubular map $[-1,1] \times X$. We write $W := N \setminus (-1,1) \times X$, we pick a base point $\star \in W$ and we pick path p in M from $*$ to $\star$.

Using Corollary 57.5 one can prove[674] the following:

(1) there exist loops $\eta_1, \dots, \eta_{n-1}$ in $(N, \star)$ such that the obvious map

$$\pi_1(W, \star) * \langle [\eta_1], \dots, [\eta_{n-1}] \rangle \ \to \ \pi_1(N, \star)$$

is an isomorphism,

(2) for each $i \in \{1, \dots, n-1\}$ the loop $p * \eta_i * \overline{p}$ is path-homotopic to $\alpha_i * \beta_i * \overline{\alpha_i}$.

Putting everything together we see that we have an isomorphism

$$\pi_1(W) * \langle [\alpha_1 * \beta_1 * \overline{\alpha_1}], \dots, [\alpha_{n-1} * \beta_{n-1} * \overline{\alpha_{n-1}}] \rangle \ \xrightarrow{\cong} \ \pi_1(M).$$

By Lemma 55.11 we know that the right-hand side is a free group of rank $n-1$. It follows from the Grushko-Neumann Theorem 51.20 that $\pi_1(W)$ is trivial. We have thus obtained the desired isomorphism.[675] ■

Exercises for Chapter 57.

Exercise 57.1. Give full details for the calculation of the fundamental group of the topological space shown in the figure on page 1297.

Exercise 57.2. Let $\pi = \langle a \rangle$, let $\Gamma = \langle t \rangle$ and let $\alpha, \beta \colon \Gamma \to \pi$ be the homomorphisms given by $\alpha(t) = a$ and $\beta(t) = a^2$. Show that the corresponding HNN-extension is isomorphic to the semidirect product $\mathbb{Z}[\frac{1}{2}]_\varphi \rtimes \mathbb{Z}$ where $\varphi \colon \mathbb{Z}[\frac{1}{2}] \to \mathbb{Z}[\frac{1}{2}]$ is the group homomorphism given by multiplication by 2.

Exercise 57.3. Let X be a path-connected topological space. Furthermore let $f \colon X \to X$ be a homeomorphism. In the Mapping Torus-π_1-Proposition 50.6 we saw that there exists an isomorphism $\psi \colon \pi_1(\mathrm{Tor}(X, f)) \cong \pi_1(X) \rtimes \mathbb{Z}$. Give an alternative proof of this statement using the HNN-Seifert–van Kampen Theorem 57.3.

---

[673] The alert reader will not have failed to notice that we are referring to an exercise that is dealt with later in the notes. Fortunately we do not need to be afraid of circular logic. The exercise builds on an extension of the Tubular Neighborhood Theorem **??** to submanifolds with boundary. This formulation, see Theorem **??**, is just a little awkward and was thus postponed to later on. But if one uses a naive extension of the Tubular Neighborhood Theorem **??** to the case of submanifolds with boundary, then one can easily prove Exercise **??** with our present knowledge.

[674] Here is the point where the demanding reader might feel that not enough details are provided.

[675] The esthetically-inclined reader might object to the use of the Grushko-Neumann Theorem 51.20. But any other approach also opens up a can of worms. For example one might be tempted to show that W is contractible.

Exercise 57.4. Let X be the result of removing two open disks from the surface of genus g. We denote by C and D the resulting boundary components. We pick orientation-preserving diffeomorphisms $\varphi\colon S^1 \to C$ and $\psi\colon S^1 \to D$.

(a) We consider the homeomorphism

$$\begin{array}{rcl} f\colon C \times S^1 & \to & D \times S^1 \\ (c, z) & \mapsto & (\psi(z), \varphi^{-1}(c)). \end{array}$$

What is the abelianization of the fundamental group of $(X \times S^1)(f)$?

(b) Does the answer to (a) change if we pick φ to be orientation-preserving and ψ to be orientation-reversing?

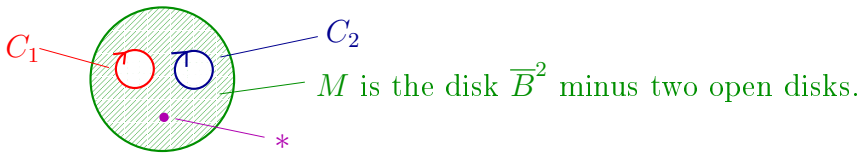
Exercise 57.5. Let X be a topological space. In the Suspension-π_1-Lemma 54.2 we showed that if X is non-empty and path-connected, then the fundamental group of the suspension $\Sigma(X)$ is trivial.

(a) Suppose that X has two path-components. Show that $\pi_1(\Sigma(X)) \cong \mathbb{Z}$.

(b) Suppose that X has k path-components with $k \geq 1$. Show that $\pi_1(\Sigma(X))$ is isomorphic to a free group on $k-1$ generators.

Exercise 57.6. We consider the permutation group S_4 where given $\alpha, \beta \in S_4$ we write $\alpha \cdot \beta = \alpha \circ \beta$. We consider the cycles[676]

$$\sigma = (1\,2\,3\,4) = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 1 \end{pmatrix}, \quad \mu = (1\,2) = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 3 & 4 \end{pmatrix} \quad \text{and } \nu = (1\,3) = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 2 & 1 & 4 \end{pmatrix}.$$



(a) Show that σ and μ form a generating set for S_4.

(b) Show that σ and ν do not form a generating set for S_4.

(c) Show that $(\mu \cdot \sigma) \cdot \mu \cdot (\mu \cdot \sigma)^{-1} = \nu$.

(d) Show that the endomorphism $\langle x, y\rangle \to \langle x, y\rangle$ that is given by $x \mapsto (yx)^{-1}x(yx)$ and $y \mapsto y$ is not an isomorphism.

(e) We consider M which is defined as the disk $\overline{B}^2$ minus two open disks[677] We consider the base point $*$ and the curves β_1 and β_2 as shown in the figure below. Show that for $i = 1, 2$ there exist paths α_i from $*$ to the starting point of β_i such that $[\alpha_1 * \beta_1 * \overline{\alpha_1}]$ and $[\alpha_2 * \beta_2 * \overline{\alpha_2}]$ do *not* form a generating set for $\pi_1(M, *)$.

[676] Recall that for pairwise disjoint $a_1, \ldots, a_k \in \{1, \ldots, n\}$ we denote by $(a_1\ a_2\ \ldots\ a_k) \in S_n$ the permutation that is given by

$$\begin{array}{rcl} \{1, \ldots, n\} & \to & \{1, \ldots, n\} \\ m & \mapsto & \begin{cases} a_{i+1}, & \text{if } m = a_i \text{ for some } i \in \{1, \ldots, k-1\}, \\ a_1 & \text{if } m = a_k, \\ m, & \text{otherwise.} \end{cases} \end{array}$$

Put differently, the numbers $(a_1, \ldots, a_k)$ get cyclically permuted and all other numbers stay the same.

[677] It follows easily from stereographic projection that M is diffeomorphic to S^2 minus three open disks.

58. Introduction to knot theory

Before we introduce knots we recall several different ways how we can describe the 3-sphere S^3. More precisely, by definition and Lemma 2.18 we have

$$S^3 = \{(z,w)\in\mathbb{C}^2 \,|\, |w|^2+|z|^2=1\} = \{(w,x,y,z)\in\mathbb{R}^4 \,|\, w^2+x^2+y^2+z^2=1\} \underset{\text{via the stereographic projection from Lemma 2.18}}{\cong} \mathbb{R}^3\cup\{\infty\}.$$

We will go back and forth between these models without mentioning these maps. In particular, as discussed on page 659, we will always view $\mathbb{R}^3$ as a submanifold of the smooth manifold $S^3 = \mathbb{R}^3 \cup \{\infty\}$.

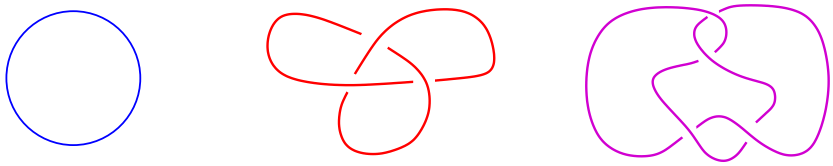
Definition. A knot is a submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1.[678] We say that the knot is oriented if it is oriented as a 1-dimensional smooth manifold.

Remark.

(1) It follows from the Smooth Embedding Theorem 24.10 that a subset of S^3 is a knot if and only if it is the image of a smooth embedding $S^1 \to S^3$.[679]
(2) The definition of a knot is supposed to model the "physical objects" that we have in mind and that are sketched in the figure below. It is therefore perhaps at first not clear why we consider knots in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ instead of knots in $\mathbb{R}^3$. The reason is that topologists prefer, if possible, to work with compact spaces. In particular the compact space $S^3 = \mathbb{R}^3 \cup \{\infty\}$ is often strongly preferable to the non-compact space $\mathbb{R}^3$.

We start out with the most boring but also the most important knot.

Definition. The trivial knot is defined as $\{(x,y,0) \in \mathbb{R}^3 \,|\, x^2+y^2 = 1\} \subset \mathbb{R}^3 \cup \{\infty\} = S^3$.



In the figure below we show the trivial knot together with two other examples of knots. More precisely, we show 1-dimensional submanifolds of $\mathbb{R}^3$ that we view as 1-dimensional submanifolds of $\mathbb{R}^3 \cup \{\infty\} = S^3$.[680]
Now we want to say that two knots are "the same" if one can be "deformed" into the other. Fortunately we already have the language to make this picture precise: The notion of a smooth isotopy between (oriented) submanifolds that we introduced on page 817 makes this notion precise. For the reader's convenience we repeat the definition of "smoothly isotopic" in our context.

---

[678] Sometimes, to distinguish this knot from the higher dimensional siblings that we will introduce on pages 1338 and **??** we also refer to such a knot as a *classical knot*.

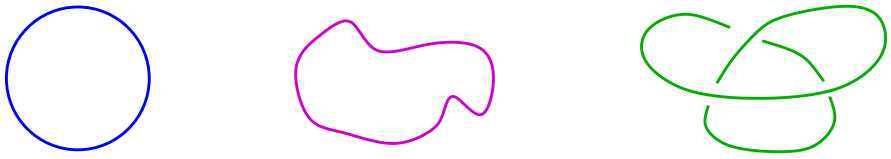
[679] To be more precise, the "if"-direction is a consequence of Theorem 24.10. On the other hand, if $K \subset S^3$ is a knot, then by definition there exists a diffeomorphism $\varphi\colon S^1 \to K \subset S^3$ and it follows easily from the definitions that the map φ viewed as a map from $S^1 \to S^3$ is a smooth embedding whose image is precisely K.

[680] In principle it is possible to give a precise description of all these three knots. For example we just gave a definition of the trivial knot as $\{(x,y,0) \,|\, x^2+y^2=1\} \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$. Later, on page 1312, we will give a precise definition of the trefoil. It is also clear that one can give a precise description of the figure-8 knot, but this description would be painful to write down and it would not add to our understanding. We therefore stick with the picture, with the understanding, that if somebody was challenging us, we could write down a precise description in coordinates. But it is considered very impolite to challenge a topologist to give a rigorous description.

trivial knot trefoil figure-8 knot

Definition. We say that two knots K and J are smoothly isotopic if there exists a smooth isotopy from K to J, i.e. a smooth map

$$\begin{aligned} F\colon S^1 \times [0,1] &\to S^3 \\ (z,t) &\mapsto F(z,t) \end{aligned}$$



such that the following hold:

(1) we have $F(S^1 \times \{0\}) = K$ and $F(S^1 \times \{1\}) = J$, and
(2) for each $t \in [0,1]$ the map $S^1 \to S^3$ given by $z \mapsto F(z,t)$ is a smooth embedding.

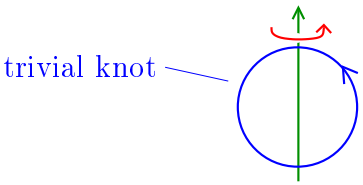
If K and J are oriented, then we demand that the map $K \to J$ given by $x \mapsto F_1(F_0^{-1}(x))$ is orientation-preserving.

Remark. It follows from the Smooth Isotopy Transitivity Proposition 33.3 that the property of being smoothly isotopic defines an equivalence relation on the set of knots.

Example. The three knots shown in the figure below are smoothly isotopic. Usually we do not distinguish two knots if they are smoothly isotopic. For example, any knot that is smoothly isotopic to a trivial knot is called *trivial knot*. Sometimes we also say that a knot that is smoothly isotopic to a trivial knot is *trivial*.

Playing around with pictures for some time shows that it might be quite difficult to show that the trefoil is smoothly isotopic to the trivial knot. This arouses the suspicion, that the trefoil is in fact not smoothly isotopic to the trivial knot. This raises the following question.

Question 58.1. How can we show that the trefoil is not smoothly isotopic to the trivial knot?



It is also fun to consider orientations. This leads us to the following definition.

Definition. A knot K is called reversible if the two orientations on K give smoothly isotopic oriented knots.[681]

Example. As we see in the figure below it is basically clear that the trivial knot is reversible. In Exercise 34.7 we showed that the trefoil and the figure-8 knot are also reversible.

This leads us to the following question which we will answer on page 2859.

[681] In the literature what we call a reversible knot is often called an invertible knot. We reserve the adjective invertible for a related, but different notion, see page 2857.

rotation around the z-axis
by the angle π turns the trivial knot
into itself but flips the orientation

Question 58.2. Is every knot reversible?

In the remainder of this section we will ignore orientations and instead we will discuss the following generalization of Question 58.1.

Question 58.3. Given a knot K[682], how can we determine whether or not K is smoothly isotopic to the trivial knot?

The following proposition allows us to turn these two questions into the question, whether two topological spaces are diffeomorphic.

Proposition 58.4. Let K and J be two knots. If they are smoothly isotopic, then the following two statements hold:

(1) There exists an orientation-preserving diffeomorphism $\Phi\colon S^3 \to S^3$ with $\Phi(K) = J$. If K and J are oriented, then Φ restricts to an orientation-preserving diffeomorphism $K \to J$.
(2) There exists an orientation-preserving diffeomorphism between the knot complements $S^3 \setminus K$ and $S^3 \setminus J$.

The proposition is basically a special case of the Smooth Isotopies-Complements Proposition 36.3. But for the reader's convenience let us recall the argument. The key input is the following (simplified) version of the Isotopy Extension Theorem 36.1.

Theorem (Isotopy Extension Theorem 36.1) Let M and K be two closed smooth manifolds. Given any smooth isotopy $F\colon K \times [0,1] \to M$ there exists a diffeotopy $G\colon M \times [0,1] \to M$ with the following properties:

(1) $G_0 = \mathrm{id}$.
(2) We have $G \circ (F_0 \times \mathrm{id}) = F\colon N \times [0,1] \to M$, in other words, we have

$$G(F_0(x), t) \;=\; F(x,t) \quad \text{for all } x \in N \text{ and } t \in [0,1].$$

Proof of Proposition 58.4. Let

$$\begin{array}{rcl} F\colon S^1 \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & F(z,t) \end{array}$$

be a smooth isotopy from a knot K to a knot J. By the Isotopy Extension Theorem 36.1 we can extend the smooth isotopy F to a diffeotopy of S^3. This means in particular that there exists a diffeotopy

$$\begin{array}{rcl} G\colon S^3 \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & G(z,t) \end{array}$$

from the identity to a diffeomorphism $\Phi = G_1\colon S^3 \to S^3$ with $\Phi|_K = F_1$, in particular with $\Phi(K) = J$. By the Smooth Isotopy-Orientation Proposition 34.2 the diffeomorphism Φ is

[682]The phrase "given a knot K" is consciously slightly vague.

orientation-preserving. The map Φ restricts to an orientation-preserving diffeomorphism $\Phi\colon S^3 \setminus K \to S^3 \setminus J$. ■

It is natural to ask to what degree the converse of Proposition 58.4 holds. It turns out that in both cases the converse holds, but in both cases these are difficult theorems. First we have the following theorem that was proved in 1969 by Jean Cerf [**Cer1968**].

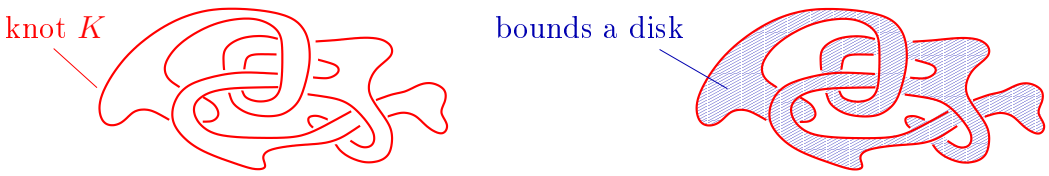
Theorem 58.5. (Cerf Theorem) Every orientation-preserving diffeomorphism of S^3 is diffeotopic to the identity.

Now we obtain the promised converse to Proposition 58.4 (1).

Corollary 58.6. Let K and J be two knots. If there exists an orientation-preserving diffeomorphism $\Phi\colon S^3 \to S^3$ with $\Phi(K) = J$, then K and J are smoothly isotopic.

Proof. Let $\Phi\colon S^3 \to S^3$ be an orientation-preserving diffeomorphism with $\Phi(K) = J$. By the Cerf Theorem 58.5 there exists a diffeotopy $F\colon S^3 \times [0,1] \to S^3$ with $F_0 = \mathrm{id}$ and $F_1 = \Phi$. The restriction of F to $[0,1] \times K$ is the desired smooth isotopy from K to J. ■

The following theorem also gives us the converse to Proposition 58.4 (2).



Theorem 58.7. (Gordon-Luecke) Let K and J be two knots in S^3. If there exists an orientation-preserving diffeomorphism between the knot complements $S^3 \setminus K$ and $S^3 \setminus J$, then K and J are smoothly isotopic.

Proof. This theorem is significantly more difficult to prove than Proposition 58.4. In fact a proof was given only in the 1980s by Cameron Gordon and John Luecke [**GL1989**, Theorem 1]. The proof builds on the work of William Thurston [**Thu1982**] for which he was awarded the Fields medal in 1982. ■

The following proposition gives a neat characterization of trivial knots.

Proposition 58.8. (Genus-Zero Knots Proposition) Let K be a knot. The following two statements are equivalent:

(1) The knot K bounds a smoothly embedded disk, i.e. there exists a smooth embedding $\varphi\colon \overline{B}^2 \to S^3$ with $\varphi(S^1) = K$.
(2) The knot K is smoothly isotopic to the trivial knot.

Proof. Let K be a knot. We need to prove the equivalence of (1) and (2).

First we prove the almost trivial "(2)⇒(1)"-direction. It is clear that the trivial knot $\{(x,y,0) \in \mathbb{R}^3 \,|\, x^2 + y^2 = 1\} \subset \mathbb{R}^3 \cup \{\infty\} = S^3$ bounds a disk. It follows immediately from the Isotopy Extension Theorem 36.1 that any knot that is smoothly isotopic to the trivial knot also bounds a smoothly embedded disk.

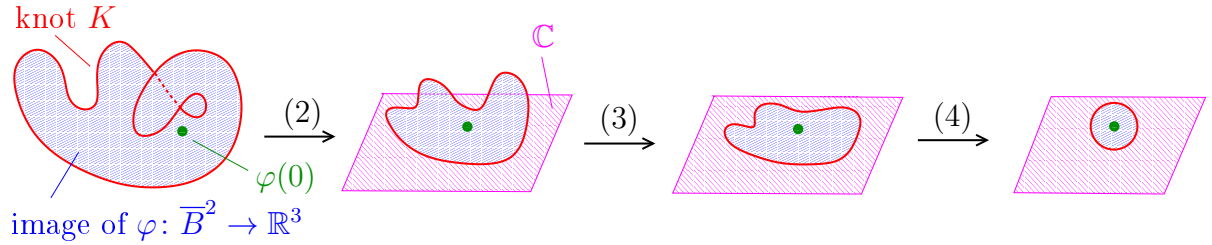
Now we turn to the proof of the much more interesting "(1)⇒(2)"-direction. In fact this is a special case of the Lower-Dimensional Smooth Ball Embedding Theorem 37.10. But to make this section slightly more self-contained we show how one can deduce this statement directly from the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2).

Thus let $\varphi\colon \overline{B}^2 \to S^3 = \mathbb{R}^3 \cup \{\infty\}$ be a smooth embedding with $\varphi(S^1) = K$. We write $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$ and we make the identification $\mathbb{C} = \mathbb{C} \times \{0\} \subset \mathbb{R}^3$. It suffices to show that there exists a smooth isotopy from φ to a smooth embedding $\psi\colon \overline{B}^2 \to \mathbb{R}^3$ such that $\psi(S^1) = S^1 \subset \mathbb{C}$. We perform the following steps:

(0) By the Matrix Group Path-Component Proposition 2.37 (3) we know that $\mathrm{SO}(4)$ is path-connected. Together with the Smooth Path-Connectivity Proposition 19.29 we see that we can find a smooth isotopy such that afterwards we have $\infty \notin \varphi(\overline{B}^2)$.

(1) Using that $\mathrm{SL}(3,\mathbb{R})$ is path-connected, see again the Matrix Group Path-Component Proposition 2.37 (2), and using again the Smooth Path-Connectivity Proposition 19.29 we can find a smooth isotopy such that afterwards we have $\varphi(0) = 0$ and $(\mathrm{D}\varphi_0)(\mathrm{T}_0\overline{B}^2) = \mathbb{C} \times \{0\}$.

(2) We can shrink the disk, i.e. we can precompose the map $\varphi\colon \overline{B}^2 \to \mathbb{C} \times \mathbb{R}$ with the smooth isotopy $\overline{B}^2 \times [\epsilon, 1] \to \overline{B}^2$ that is given by $(p,t) \mapsto p \cdot t$ for some $\epsilon \in (0,1]$, such that composition $p \circ \varphi$ of φ with the projection $p\colon \mathbb{R}^3 = \mathbb{C} \times \mathbb{R} \to \mathbb{C}$ is an embedding.



(3) We write $\varphi = \varphi_{\mathbb{C}} \times \varphi_{\mathbb{R}}\colon \overline{B}^2 \to \mathbb{C} \times \mathbb{R}$. It follows from (2) that the map

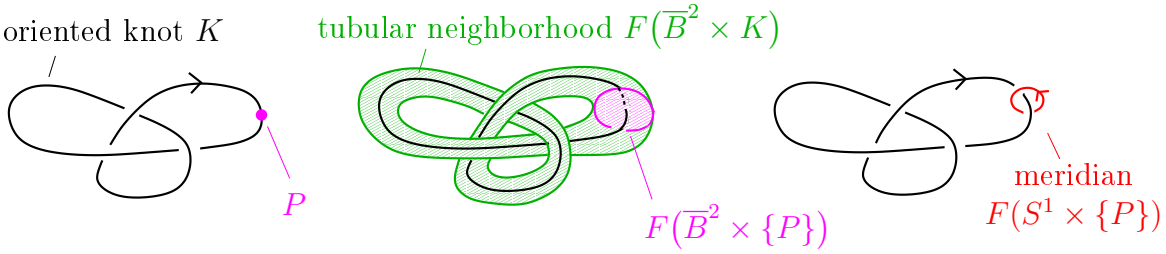
$$\begin{array}{rcl} \overline{B}^2 \times [0,1] & \to & \mathbb{C} \times \mathbb{R} \\ (x,t) & \mapsto & (\varphi_{\mathbb{C}}(x), \varphi_{\mathbb{R}}(x) \cdot t) \end{array}$$

is a smooth isotopy. This shows that we only need to deal with a smooth embedding $\varphi\colon \overline{B}^2 \to \mathbb{C}$ with $\varphi(0) = 0$.

(4) Now we can apply the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2).

We illustrate the steps (2) to (4) in the figure below. We leave it to the reader to fill in all the technical details and to make all steps rigorous. ■

We continue our discussion of knots with a definition.



Definition. Let K be an oriented knot in S^3. By the Tubular Neighborhood Theorem **??** there exists an orientation-preserving smooth embedding

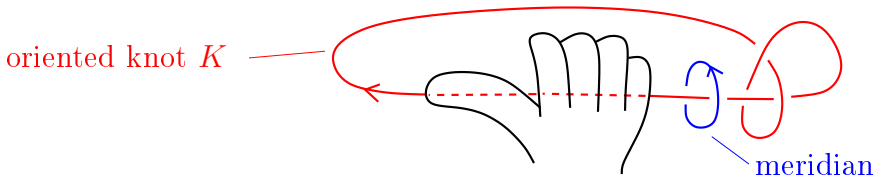
$$F\colon \overline{B}^2 \times K \to S^3$$

such that $F(0,P) = P$ for all $P \in K$. For any $P \in K$ we refer to the oriented submanifold[683] $F(S^1 \times \{P\})$ as a meridian of K.

A priori the definition of the meridian depends on the choice of the tubular neighborhood. The following lemma, which is an immediate consequence of Proposition **??**, says that the meridian is well-defined up to smooth isotopy.

[683]It follows immediately from the Smooth Embedding Theorem 24.10 that $F(S^1 \times \{P\})$ is indeed a submanifold of $S^3 \setminus K$.

Lemma 58.9. The meridian of an oriented knot in S^3 is well-defined up to smooth isotopy in $S^3 \setminus K$.



The following proposition gives a convenient criterion for showing that a given closed oriented curve is indeed a meridian.

Proposition 58.10. Let K be an oriented knot in S^3. Let $\mu \subset S^3 \setminus K$ be a closed oriented curve. Suppose there exists a smooth embedding $\varphi\colon \overline{B}^2 \subset S^3$ with the following two properties:

(1) the map $\varphi|_{S^1}$ defines an orientation-preserving diffeomorphism $S^1 \to \mu$,
(2) the image $\varphi(\overline{B}^2)$ intersects K transversally in a single point P,
(3) a positive basis for $\mathrm{T}_P(\varphi(\overline{B}^2))$ together with a positive basis for $\mathrm{T}_P K$ gives a positive basis for $\mathrm{T}_P S^3$,[684]

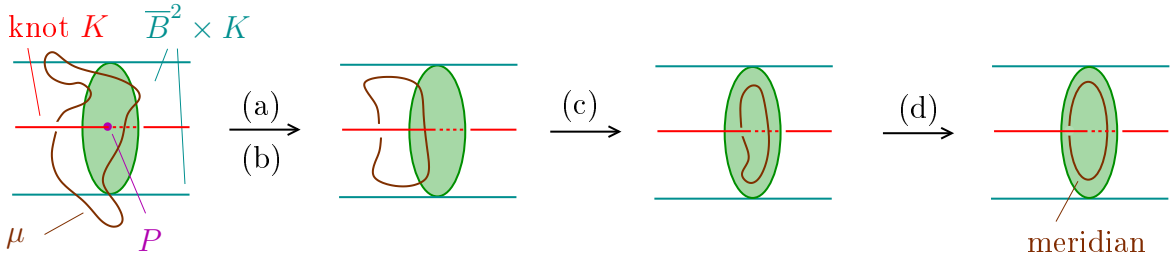
then μ is a meridian of K.

Remark. More casually speaking, Proposition 58.10 says that a meridian is any closed curve which circles once around a knot where the orientation is given by the right-hand-rule, i.e. if the thumb points into the direction of the knot, then the fingers point into the direction of the meridian. This rule is illustrated in the figure below.

Sketch of proof. By the Tubular Neighborhood Theorem **??** there exists an orientation-preserving smooth embedding $F\colon \overline{B}^2 \times K \to S^3$ such that $F(0, P) = P$ for all $P \in K$. For convenience we denote the image of F by $\overline{B}^2 \times K$. We perform the following steps which are quite similar to the steps in the proof of the Genus-Zero Knots Proposition 58.8.

(a) We pick a point $Q \neq P$ on K. We can shrink the disk such that $\varphi(\overline{B}^2)$ is contained in $\overline{B}^2 \times (K \setminus \{Q\})$.
(b) It follows from our hypothesis (1) and the definition of differentiability that we can shrink the disk even further, such that the map

$$\overline{B}^2 \xrightarrow{\varphi} \overline{B}^2 \times (K \setminus \{Q\}) \xrightarrow{(v,z)\mapsto(v,P)} \overline{B}^2 \times \{P\}$$



[684] Later, on page 2748, we will say that P is a positive intersection point of $\varphi(\overline{B}^2)$ and K.

is an embedding. It follows from the hypothesis (2) that this map is actually orientation-preserving.

(c) Similar to Step (3) of the proof of the Genus-Zero Knots Proposition 58.8 we see that φ is smoothly isotopic, rel $(0, P)$, to an orientation-preserving embedding into $\overline{B}^2 \times \{P\}$.

(d) The statement now follows from the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 (2).

As in the proof of the Genus-Zero Knots Proposition 58.8 we leave it to the reader to fill in the details. ■

test test

Later on, in Chapter 59, we will study the fundamental group of a knot complement. Implicitly we will make use of the following lemma.

Lemma 58.11. Given any knot $K \subset S^3$ the complement $S^3 \setminus K$ is path-connected.

Proof. We will provide the proof in Exercise **??**. ■

59. An excursion into knot theory

In this chapter we will study the fundamental groups of the complements of knots. In particular we will use these calculations to show that the trivial knot, the trefoil and the figure-8 knot are pairwise different, i.e. we will show that they are pairwise not smoothly isotopic.

59.1. **One more avatar of spheres.** The spheres $S^n = \{x \in \mathbb{R}^{n+1} \,|\, \|x\| = 1\}$ are some of the most important topological spaces. We already saw that there are different ways to think about spheres, in particular on pages 156 and 261 and in the Ball-Quotient Sphere Lemma 5.20 we made the following identifications

$$S^n = \mathbb{R}^n \cup \{\infty\}, \quad S^n = \overline{B}^n/S^{n-1}, \quad \text{and} \quad S^n = \overline{B}^n_+ \cup_{S^{n-1}} \overline{B}^n_-.$$

Furthermore, on page 263 we had given a canonical homeomorphism

$$(S^{m-1} \times \overline{B}^n) \cup_{S^{m-1}\times S^{n-1}} (\overline{B}^m \times S^{n-1}) \xrightarrow{\cong} S^{m+n-1}.$$

Even though the homeomorphism is canonical, it is not particularly explicit. Furthermore it has the disadvantage that, if one looks up the definition, one sees that the restriction to the two solid tori $S^{m-1} \times \overline{B}^n$ and $\overline{B}^m \times S^{n-1}$ is not smooth. The following lemma rectifies these two problems.

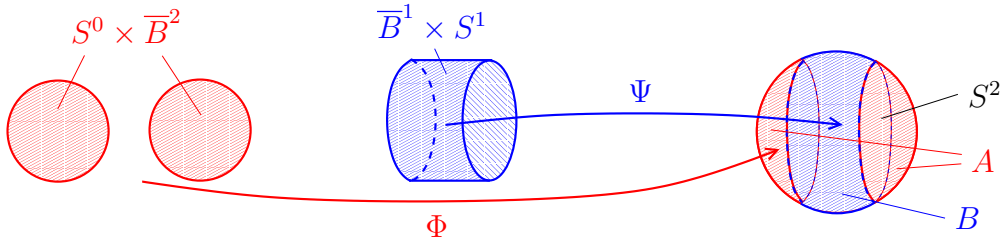
Lemma 59.1. Let $m, n \in \mathbb{N}_0$. We consider the following two maps:

$$\begin{array}{rcl} \Phi\colon S^{m-1} \times \overline{B}^n & \to & A := \left\{(z,w) \in \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n} \,\middle|\, \|w\|^2 + \|z\|^2 = 1 \text{ and } \|z\|^2 \geq \frac{1}{2}\right\} \\ (a,b) & \mapsto & \left(\frac{a}{\sqrt{\|a\|^2+\|b\|^2}}, \frac{b}{\sqrt{\|a\|^2+\|b\|^2}}\right) \end{array}$$

and

$$\begin{array}{rcl} \Psi\colon \overline{B}^m \times S^{n-1} & \to & B := \left\{(z,w) \in \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n} \,\middle|\, \|w\|^2 + \|z\|^2 = 1 \text{ and } \|w\|^2 \geq \frac{1}{2}\right\} \\ (a,b) & \mapsto & \left(\frac{a}{\sqrt{\|a\|^2+\|b\|^2}}, \frac{b}{\sqrt{\|a\|^2+\|b\|^2}}\right). \end{array}$$

These maps have the following properties:



(1) The map $\Phi\colon S^{m-1} \times \overline{B}^n \to A$ is an orientation-preserving diffeomorphism.
(2) The map $\Psi\colon \overline{B}^m \times S^{n-1} \to B$ is a diffeomorphism, it is orientation-preserving if and only if m is even.
(3) The map[685]

$$\begin{array}{rcl} \Theta\colon (S^{m-1} \times \overline{B}^n) \cup_{S^{m-1}\times S^{n-1}} (\overline{B}^m \times S^{n-1}) & \to & S^{m+n-1} \\ [P] & \mapsto & \begin{cases} \Phi(P), & \text{if } P \in S^{m-1} \times \overline{B}^n, \\ \Psi(P), & \text{if } P \in \overline{B}^m \times S^{n-1} \end{cases} \end{array}$$

is well-defined, it is a diffeomorphism, and it is orientation-preserving if and only if m is even.

[685] We equip the boundaries of $S^{m-1} \times S^n$ and $\overline{B}^m \times S^{n-1}$ with the "obvious" collars. We use these collars and the Gluing-Smooth Manifolds-Proposition ?? (1b) to equip the left-hand side with the structure of a smooth manifold. Furthermore we use the Gluing-Smooth Manifolds-Proposition ?? (6) to equip the left-hand side with the orientation, where the orientation matches the orientation of $S^{m-1} \times \overline{B}^n$ and which matches the orientation of $\overline{B}^m \times S^{n-1}$ if and only if m is even.

Convention. We use the diffeomorphism Θ from Lemma 59.1 (2) to add the smooth manifold $(S^{m-1}\times\overline{B}^n)\cup_{S^{m-1}\times S^{n-1}}(\overline{B}^m\times S^{n-1})$ to our list of avatars of S^{m+n-1}.

Sketch of proof.

(2) Since the orientations are a little more interesting in the second case let us treat the second case in detail. We consider the map

$$\begin{aligned}\widetilde{\Psi}\colon B=\big\{(z,w)\in\mathbb{R}^m\times\mathbb{R}^n=\mathbb{R}^{m+n}\;\big|\;\|w\|^2+\|z\|^2=1\;\&\;\|w\|^2\geq\tfrac{1}{2}\big\}\;&\to\;\overline{B}^m\times S^{n-1}\\(z,w)\;&\mapsto\;\Big(\tfrac{z}{\|w\|},\tfrac{w}{\|w\|}\Big).\end{aligned}$$

One can easily verify that $\widetilde{\Psi}$ and Ψ are inverses of one another and that Ψ and $\widetilde{\Psi}$ are smooth. This observation implies that $\Psi\colon\overline{B}^m\times S^{n-1}\to B$ is a diffeomorphism. It remains to show that Ψ is orientation-preserving. By the Basics-of-Orientations Lemma 25.13 it suffices to prove the following claim.

Claim. For $e_{m+1}=((0,\dots,0),(1,0,\dots,0))\in\overline{B}^m\times S^{n-1}$ the corresponding differential $\mathrm{D}\Psi_{e_{m+1}}\colon\widetilde{\mathrm{T}}_{e_{m+1}}(\overline{B}^m\times S^{n-1})\to\widetilde{\mathrm{T}}_{\Psi(e_{m+1})}B$ is orientation-preserving if and only if m is even.

Proof. By the orientation conventions from page 681 and the Smooth Manifold Product Proposition 19.31 we know that $\{e_1,\dots,e_m,e_{m+2},\dots,e_{m+n}\}$ is a positive basis for $\widetilde{\mathrm{T}}_{e_{m+1}}(\overline{B}^m\times S^{n-1})$. First note that a straightforward calculation shows that the differential of Ψ at the point e_{m+1} is actually the identity. Next note that $\Psi(e_{m+1})=e_{m+1}$. Finally note that by definition $\{v_1,\dots,v_{m+n-1}\}$ is a positive basis for $\widetilde{\mathrm{T}}_{\Psi(e_{m+1})}B=\widetilde{\mathrm{T}}_{e_{m+1}}S^{m+n-1}$ if and only if $\det(e_{m+1},v_1,\dots,v_{m+n-1})>0$. The claim follows almost immediately from these observations. ⊞

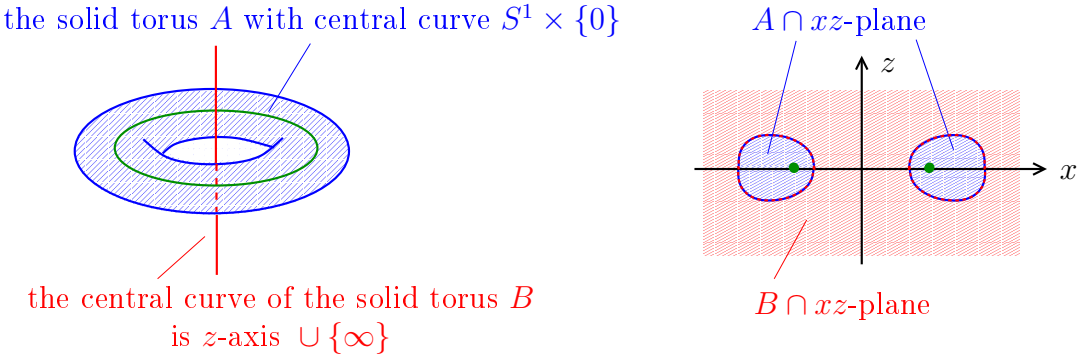
(1) The proof of this statement is almost identical to the above proof of (2).

(3) It is clear that Φ and Ψ agree on $S^{m-1}\times S^{n-1}$. Therefore it follows from the Topological-Quotient Proposition 5.15 (1b) that the given map $\Theta\colon(S^{m-1}\times\overline{B}^n)\cup_{S^{m-1}\times S^{n-1}}(\overline{B}^m\times S^{n-1})\to S^{m+n-1}$ is well-defined and continuous. Using (1) one easily verifies that the map is a bijection. It follows from the Compact-Hausdorff Proposition 2.17 (3) that the map Θ is a homeomorphism. Going through the definition of the smooth structure of the smooth manifold on the left, as defined in the Gluing-Smooth Manifolds-Proposition **??** (1b), shows that the map is actually a diffeomorphism. Finally it follows from (1) and (2) that the diffeomorphism is actually orientation-preserving. ■

Throughout this chapter we are mostly interested in the case $m = n = 2$. In this setting we have the following identifications which are given by definition and b Lemma 2.18:

$$S^3 = \big\{(w,x,y,z)\,\big|\,w^2+x^2+y^2+z^2=1\big\} = \big\{(z,w)\in\mathbb{C}^2\,\big|\,|w|^2+|z|^2=1\big\} \underset{\uparrow}{=} \mathbb{R}^3\cup\{\infty\}.$$

via the stereographic projection as defined in Lemma 2.18
note that in Exercise 25.9 we saw that this map
is (lucky us!) orientation-preserving



We will go back and forth between these models without mentioning these maps. In particular, as discussed on page 659, we will view $\mathbb{R}^3$ as a submanifold of the smooth manifold $S^3 = \mathbb{R}^3\cup\{\infty\}$. Furthermore we now view A and B as subsets of $S^3 = \mathbb{R}^3\cup\{\infty\}$. In this setting we have

$$\text{“central curve of } A\text{”} = \Phi(S^1\times\{0\}) = S^1\times\{0\} = \text{the trivial knot}$$

and we have

$$\text{“central curve of } B\text{”} = \Psi(\{0\}\times S^1) = \text{the } z\text{-axis}\cup\{\infty\}.$$

We visualize the solid torus A and the central curve of the solid torus B in the figure below. The solid torus B is more difficult to illustrate. It consists of a closed disk attached to each point on the central curve. For example the closed disk attached to the origin is just the “obvious” closed disk in the xy-plane that touches the torus $\Phi(S^1\times S^1)$.[686]

Lemma 5.7 and Lemma 59.1 give us two smooth embeddings of the 2-dimensional torus $S^1\times S^1$ into $\mathbb{R}^3$. The following lemma says that these two smooth embeddings are essentially the same.

Lemma 59.2. We denote by $\Omega\colon S^3\setminus\{(0,1)\}\to\mathbb{R}^3$ the stereographic projection as defined in Lemma 2.18. We consider the two smooth embeddings[687][688]

$$\begin{aligned}\overline{B}^2\times S^1 &\xrightarrow{\Theta} \mathbb{R}^3 \\ ((x,y),\exp(\mathrm{i}\varphi)) &\mapsto \begin{pmatrix}\cos\varphi & -\sin\varphi & 0\\ \sin\varphi & \cos\varphi & 0\\ 0 & 0 & 1\end{pmatrix}\cdot\begin{pmatrix}1+\frac{x}{2}\\ 0\\ -\frac{y}{2}\end{pmatrix}\end{aligned}$$

and

$$\begin{aligned}\overline{B}^2\times S^1 &\xrightarrow{\Xi} S^3\setminus\{(0,1)\} \xrightarrow{\Omega} \mathbb{R}^3 \\ (z,w) &\mapsto \Big(\tfrac{w}{\sqrt{|z|^2+|w|^2}}, \tfrac{z}{\sqrt{|z|^2+|w|^2}}\Big)\end{aligned}$$

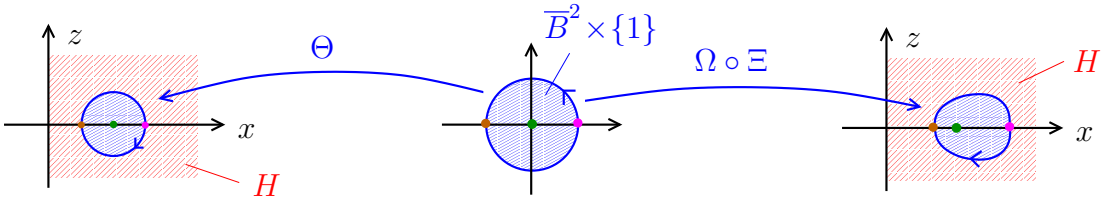
provided by Lemma 5.7 and provided by Lemma 59.1. There exists a diffeotopy G of S^3 rel $\{(0,0)\}\times S^1$ with $G_0 = \mathrm{id}$ and $G_1\circ\Theta = \Omega\circ\Xi$.

---

[686] What is the disk attached to the point ∞?

[687] Note that $\Xi\colon \overline{B}^2\times S^1\to S^3$ is just the composition of the swap $\overline{B}^2\times S^1\to S^1\times\overline{B}^2$ and the smooth embedding $\Phi\colon S^1\times\overline{B}^2\to S^3$.

[688] As a reality check note that it follows from Lemma 2.18 that Θ and $\Omega\circ\Xi$ agree on $\{(0,0)\}\times S^1$.



Convention. In all the future examples we will not distinguish between the two smooth embeddings of the solid torus $\overline{B}^2 \times S^1 \to \mathbb{R}^3$ that are given in Lemma 59.2.

Sketch of proof. By the Isotopy Extension Theorem 36.1 it suffices to show that there exists a smooth isotopy rel $\{(0,0)\} \times S^1$ from Θ to $\Omega \circ \Xi$.

We write $H = \{(x,0,z) \in \mathbb{R}^3 \,|\, x > 0\}$. Let us first consider the restrictions of Θ and $\Omega \circ \Xi$ to the disk $\overline{B}^2 \times \{1\}$. In both cases the image lies in H. These maps are illustrated in the figure below. We leave it to the dear reader to show that there exists a smooth isotopy $F\colon \overline{B}^2 \times \{1\} \times [0,1] \to H$ rel $\{(0,0,1)\}$ from Θ to $\Omega \circ \Xi$.

The desired isotopy is given by "rotating F" around the z-axis. Slightly more precisely it is given by the map

$$\begin{array}{rcl} \overline{B}^2 \times S^1 \times [0,1] & \to & \mathbb{R}^3 \\ ((x,y), \exp(\mathrm{i}\varphi), t) & \mapsto & \text{rotation of } F((x,y),t) \in \mathbb{R}^3 \text{ by } \varphi \text{ around the } z\text{-axis.} \end{array}$$ ■

59.2. **The fundamental group of the complement of the trefoil.** Now we want to finally turn to the study of knots. For the reader's convenience we recall the relevant definitions from page 1301 and 1302.

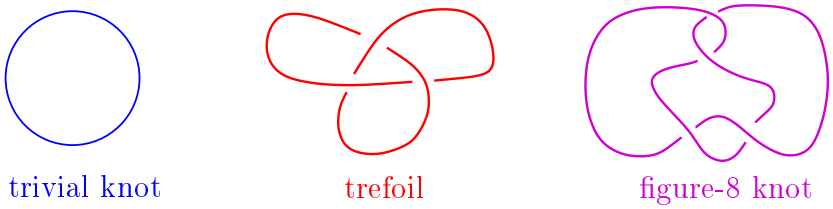
Definition.

(1) A knot is a submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1.[689] We say that the knot is oriented if it is oriented as a 1-dimensional smooth manifold.

(2) We say that two knots K and J are smoothly isotopic if there exists a smooth isotopy from K to J, i.e. a smooth map

$$\begin{array}{rcl} F\colon S^1 \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & F(z,t) \end{array}$$

such that the following hold:



(a) we have $F(S^1 \times \{0\}) = K$ and $F(S^1 \times \{1\}) = J$, and

(b) for each $t \in [0,1]$ the map $S^1 \to S^3$ given by $z \mapsto F(z,t)$ is a smooth embedding.

If K and J are oriented, then we demand that the map $K \to J$ given by $x \mapsto F_1(F_0^{-1}(x))$ is orientation-preserving.

In the following we would like to study the knots that are illustrated in the figure below. In Question 58.1 we had raised the question, how can one show that the trefoil is not trivial, i.e. not smoothly isotopic to the trivial knot?

Now we have some tools to attack this question. We saw in Proposition 58.4 that if K and J are smoothly isotopic knots, then the knot complements $S^3 \setminus K$ and $S^3 \setminus J$ are diffeomorphic. In particular if $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus J)$ are not isomorphic, then K and J are not smoothly isotopic. Thus we arrive at the following variation on Question 58.1.

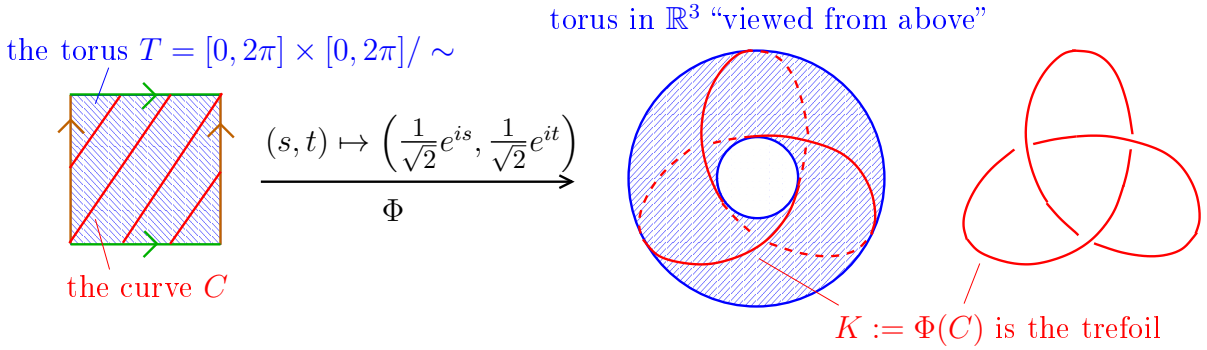
Question 59.3. Can the fundamental group be used to distinguish the trefoil from the trivial knot?

Before we continue we want to give a precise description of the trivial knot and the trefoil. In fact, we will use the occasion to introduce an interesting family of knots which contains the trefoil knot.

Definition.

(1) As on page 1301 we define the trivial knot as the knot[690]

$$U := \{(\exp(it), 0) \mid t \in \mathbb{R}\} \subset \left\{(z,w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1\right\}$$



or equivalently

$$U := \{(\cos t, \sin t, 0) \mid t \in \mathbb{R}\} \subset \mathbb{R}^3 \cup \{\infty\}.$$

(2) Let $p, q \in \mathbb{N}$ be coprime. We consider the curve $C = \{(p \cdot t, q \cdot t) \mid t \in \mathbb{R}\}$ on the torus $T = [0, 2\pi] \times [0, 2\pi]/\sim$. We define the (p,q)-torus knot $T(p,q)$ as the image of C under the map

$$\begin{aligned} \Phi\colon T = [0,2\pi] \times [0,2\pi]/\sim &\to S^3 \\ (s,t) &\mapsto \left(\tfrac{1}{\sqrt{2}} \exp(is), \tfrac{1}{\sqrt{2}} \exp(it)\right). \end{aligned}$$

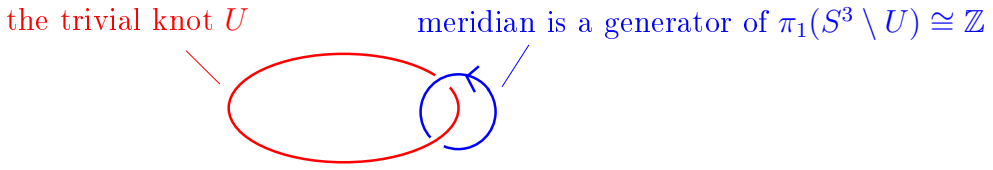
(3) We define the trefoil to be the $(2,3)$-torus. This definition of the trefoil is illustrated in the figure below.

Now we turn to the calculation of the fundamental groups of the complements of the trivial knot and of the trefoil.

Proposition 59.4. If U is the trivial knot, then $S^3 \setminus U$ is diffeomorphic to $S^1 \times \mathbb{C}$, in particular $\pi_1(S^3 \setminus U) \cong \mathbb{Z}$.

[690] The name U comes from the fact that the trivial knot is often also called the *unknot*.

Proof. Note that



$$\begin{aligned} S^3 \setminus U &= \{(z,w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1\} \setminus \{(z,0) \mid |z| = 1\} \\ &= \{(z,w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1 \text{ and } |w|^2 > 0\}. \end{aligned}$$

Now basically the same argument as in the proof of Lemma 59.1 shows that the map

$$\begin{aligned} \Phi\colon S^1 \times \mathbb{C} &\to S^3 \setminus U = \left\{(z,w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |w|^2 > 0\right\} \\ (a,b) &\mapsto \left(\frac{b}{\sqrt{|a|^2+|b|^2}}, \frac{a}{\sqrt{|a|^2+|b|^2}}\right) \end{aligned}$$

is a diffeomorphism. Since $S^1 \times \mathbb{C}$ is homotopy equivalent to S^1 we obtain from the above and from the Homotopy-π_1-Proposition 50.3 (2) that $\pi_1(S^3 \setminus U) = \pi_1(S^1 \times \mathbb{C}) = \pi_1(S^1) \cong \mathbb{Z}$. ∎

Remark. Let U be the trivial knot. A careful reading of the proof of Proposition 59.4 shows that a generator of $\pi_1(S^3 \setminus U)$ is given by a meridian that we defined on page 1305. We refer to the figure below for an illustration of the trivial knot and a meridian.

Proposition 59.5.
(1) Let $p, q \in \mathbb{N}$ be coprime. Then $\pi_1(S^3 \setminus T(p,q)) \cong \langle x, y \mid x^p = y^q \rangle$.
(2) If K is the trefoil, then $\pi_1(S^3 \setminus K) \cong \langle x, y \mid x^2 = y^3 \rangle$.

Proof. By definition of the trefoil Statement (2) is just a special case of Statement (1). Thus we only need to prove Statement (1). Let $p, q \in \mathbb{N}$ be coprime. By Lemma 59.1 there exists a diffeomorphism

$$\Phi\colon S^3 \xrightarrow{\cong} \underbrace{\left(S^1 \times \overline{B}^2\right)}_{=:A} \cup_{S^1 \times S^1 = S^1 \times S^1} \underbrace{\left(\overline{B}^2 \times S^1\right)}_{=:B}$$

which is, up to scaling by a factor of $\sqrt{2}$, the identity on $T := S^1 \times S^1$. We identify the (p,q)-torus knot with its image under Φ, i.e. we have

$$K \;=\; \{(\exp(ps\mathrm{i}), \exp(qs\mathrm{i})) \mid s \in \mathbb{R}\} \;\subset\; T.$$

We write $A_K = A \setminus K, B_K = B \setminus K$ and $T_K = T \setminus K$. Note that A_K and B_K are submanifolds of $X_K := S^3 \setminus K$ and with[691] $A_K \cap B_K = \partial A_k = \partial B_K = T_K$ and with $A_K \cup B_K = X_K$. Note that $x := S^1 \times \{0\}$ is a deformation retract of A_K and that $y := \{0\} \times S^1$ is a deformation retract of B_K. Finally note that T_K retracts onto a parallel copy of K. More precisely, for $\epsilon > 0$ sufficiently small, the subset T_K retracts onto the loop

$$z \;=\; \{(\exp(ps\mathrm{i} + \epsilon), \exp(qs\mathrm{i})) \mid s \in \mathbb{R}\} \;\subset\; T_K.$$

[691] Here we mean by ∂A_K and ∂B_K the boundary of A_K and B_K viewed as submanifolds of S^3.

By an abuse of notation we denote by x, y and z also the loops corresponding to the circles x, y and z with the obvious orientation. Then the inclusion induced maps

$$\begin{array}{ccccc} \pi_1(A_K) & \leftarrow & \pi_1(T_K) & \rightarrow & \pi_1(B_K) \\ i_*(g) & \mapsfrom & g & \mapsto & j_*(g) \end{array} \quad \text{become} \quad \begin{array}{ccccc} \langle x\rangle & \leftarrow & \langle z\rangle & \rightarrow & \langle y\rangle \\ x^p & \mapsfrom & z & \mapsto & y^q. \end{array}$$

Thus we see that

$$\begin{array}{ccccccc} \pi_1(X_K) & = & \pi_1(A_K) *_{\pi_1(T_K)} \pi_1(B_K) & \cong & \langle x\rangle *_{x^p=y^q} \langle y\rangle & = & \langle x, y \mid x^p = y^q\rangle. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Seifert–van Kampen Theorem 54.4} & & \text{above discussion} & & \text{Lemma 53.23} & \end{array}$$

■

Now the question is whether or not $\pi_1(S^3 \setminus K) = \langle x, y \mid x^2 = y^3\rangle$ is isomorphic to $\pi_1(S^3 \setminus U) = \mathbb{Z}$. As usual we first consider the abelianization of $\pi_1(S^3 \setminus K)$, but it is straightforward to see, using the Abelianization Proposition 53.20 that the abelianization is isomorphic to $\mathbb{Z}$.[692][693] Despite this slight setback the following lemma does fortunately show that the group $\pi_1(S^3 \setminus K) = \langle x, y \mid x^2 = y^3\rangle$ is not isomorphic to $\pi_1(S^3 \setminus U) = \mathbb{Z}$.

Proposition 59.6.

(1) The group $\langle x, y \mid x^2 = y^3\rangle$ admits an epimorphism onto the permutation group S_3, in particular the group $\langle x, y \mid x^2 = y^3\rangle$ is non-abelian and it is not isomorphic to $\mathbb{Z}$.
(2) The trefoil is not smoothly isotopic to the trivial knot.

Proof.

(1) It follows from Lemma 53.4 and a straightforward calculation that there exists a unique homomorphism

$$\begin{array}{rcl} \Phi\colon \langle x, y \mid x^2 = y^3\rangle & \rightarrow & S_3 = \text{permutation group on three elements} \\ \text{with} \quad \Phi(x) & = & \sigma := (1\,2) = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} \\ \text{and} \quad \Phi(y) & = & \tau := (1\,2\,3) = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}. \end{array}$$

The permutations σ and τ do not commute, hence the image of Φ is a non-abelian subgroup of S_3.[694] On the other hand the abelian group $\mathbb{Z}$ cannot admit an epimorphism onto a non-abelian group[695].

(2) It follows from (1) and above discussion that the trefoil is non-trivial. ■

The following question arises naturally.

Question 59.7. Are the (p, q)-torus knots pairwise different, i.e. if (p, q) and (r, s) for coprime pairs of natural numbers, does it follow that $T(p, q)$ and $T(r, s)$ are not smoothly isotopic?

The approach of the proof of Proposition 59.6 is most likely too pedestrian to deal with Question 59.7. We will return to Question 59.7 at a much later stage.

---

[692] In fact that is not a coincidence, using homology groups we will soon see that for any knot J the abelianization of $\pi_1(S^3 \setminus J)$ is isomorphic to $\mathbb{Z}$.

[693] If one goes very carefully through the definitions and calculations then one can see that a meridian once again becomes a generator of the abelianization.

[694] In fact it is easy to see that the only non-abelian subgroup of S_3 is S_3 itself, i.e. Φ is an epimorphism onto S_3.

[695] Why not?

Remark. Let $p, q \in \mathbb{N}$ be coprime. We consider the map

$$\begin{aligned} f\colon S^3 = \{(z,w) \in \mathbb{C}^2 \,|\, |z|^2 + |w|^2 = 1\} &\to \mathbb{C} \\ (z,w) &\mapsto z^q - w^p. \end{aligned}$$

Note that by definition the (p,q)-torus knot $T(p,q)$ equals $f^{-1}(0)$. It follows from work of Milnor, see [**Miln1968**, Theorem 4.8] and [**Sav2012**, Chapter 8] (see also [**EN1985**, p. 125] and [**Rolf1990**, Chapter 10.I]), that there exists a surface and a self-diffeomorphism of order pq together with a diffeomorphism $\Theta\colon S^3 \setminus T(p,q) \to \mathrm{Tor}(\Sigma, \varphi)$ such that the following diagram commutes

$$\begin{array}{ccc} S^3 \setminus T(p,q) & \xrightarrow[\cong]{\Theta} & \mathrm{Tor}(\Sigma,\varphi) \\ & {\scriptstyle P \mapsto \frac{f(P)}{|f(P)|}} \searrow \quad \swarrow {\scriptstyle [(z,t)] \mapsto \exp(2\pi i t)} & \\ & S^1. & \end{array}$$

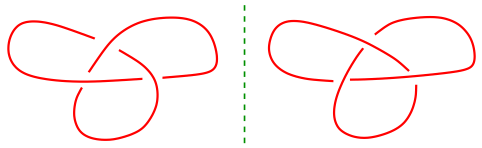
This generalizes the observation from 470 that the complement of the trefoil is diffeomorphic to a mapping torus.

The question arises, whether the fundamental group is strong enough to detect the smooth isotopy class of a knot. In the section we will see that this is perhaps a trifle to optimistic.

59.3. **The mirror image of a knot.** We continue with the following nicely geometric definition.

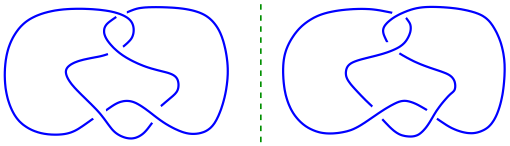
Definition. Given a knot $K \subset S^3$ the reflection of K in any hyperplane of $\mathbb{R}^4$ is called mirror of K and denoted by K^{mir}.

Lemma 59.8.



(1) Let $K \subset S^3$ be a knot. The reflections in any two hyperplanes of $\mathbb{R}^4$ give rise to smoothly isotopic knots.
(2) Let $K \subset \mathbb{R}^3$ be a knot. We use the diffeomorphism $\mathbb{R}^3 \cup \{\infty\} \to S^3$ from Lemma 2.18 to view K as a knot in S^3. The image of K under a reflection of an affine hyperplane in $\mathbb{R}^3$ corresponds under this embedding to a mirror of K.

Sketch of proof.



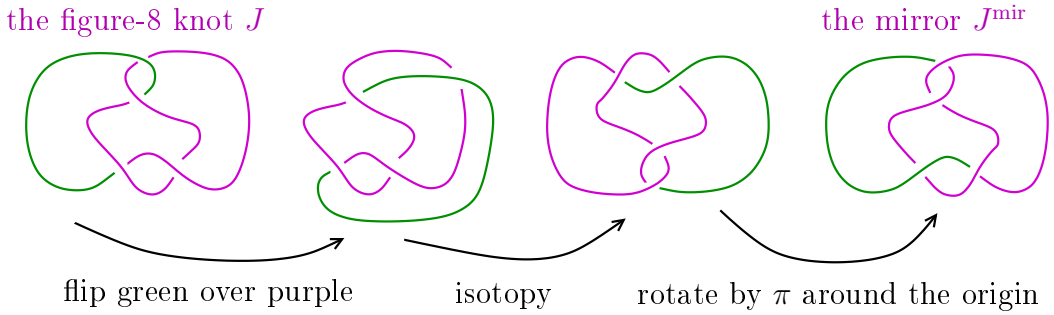
(1) We will prove this statement in Exercise 59.1, making use of the Matrix Group Path-Component Proposition 2.37 and the Smooth Path-Connectivity Proposition 19.29.
(2) Let $K \subset \mathbb{R}^3$ be a knot. First note that the same argument as in (1) shows that reflection in any two affine hyperplanes of $\mathbb{R}^3$ lead to smoothly isotopic knots in $\mathbb{R}^3$. Thus it remains to show that there exists a single hyperplane H of $\mathbb{R}^3$ such that the reflection of K in H corresponds to the mirror image of $K \subset \mathbb{R}^3 \subset S^3$ as defined above. Next note that the stereographic projection, that we used in Lemma 2.18, commutes with the reflection in the $(x_1 = 0)$-hyperplane of $\mathbb{R}^4$ respectively $\mathbb{R}^3$. Thus we see that the hyperplane $(x_1 = 0)$ has the desired property. ∎

Convention. Let $K \subset S^3$. Since usually we only care about knots up to smooth isotopy we use Lemma 59.8 to talk of "the mirror image" of K instead of the slightly more correct "a mirror image of K".

Example. Let $K \subset \mathbb{R}^3 \subset \mathbb{R}^3 \cup \{\infty\} = S^3$ be a knot. Keeping Lemma 59.8 (2) we see in the figure below the trefoil and its mirror and we also see the figure-8 knot and its mirror.

the trefoil K and its mirror K^{mir}

the figure-8 knot J and its mirror J^{mir}



The question arises, whether the mirror image of a knot is "truly different" from the original knot. We are now naturally led to the following definition.

Definition. We say that a knot K in $\mathbb{R}^3$ is amphichiral if it is smoothly isotopic to its mirror image, otherwise we call the knot K chiral.

Examples.

(1) The trivial knot equals of course its mirror, in particular the trivial knot is amphichiral.

(2) In the figure below we show that the figure-8 knot J is smoothly isotopic to its mirror image J^*, i.e. the figure-8 knot is also amphichiral.

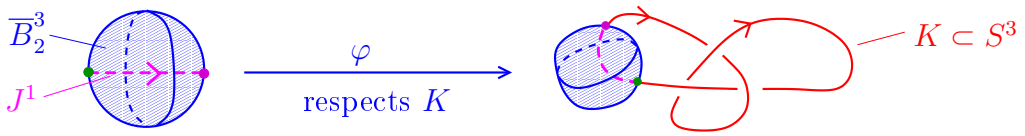
It is now natural to ask whether the trefoil is amphichiral. But endless hours of playing around with the trefoil do not lead to any success. So the suspicion arises that the following question should be answered in the negative.

Question 59.9. Is the trefoil chiral?

Much later, in Proposition 131.5 and 149.10 we will use two different approaches to give negative answer to this question. In the first approach we use the fundamental group together with the "longitude", in the latter approach we use linking pairings of the "2-fold branched covering of K".

We return to the study of fundamental groups. Let $K \subset S^3$ be a knot and let K^{mir} be its mirror image. Evidently $S^3 \setminus K$ is diffeomorphic to $S^3 \setminus K^{\text{mir}}$, so we cannot hope to distinguish K and K^{mir} using the fundamental groups of their complements. This leads us to the following question:

Question 59.10. Let K and J be two knots such that the fundamental groups of $S^3 \setminus K$ and $S^3 \setminus J$ are isomorphic. Does this imply that K is smoothly isotopic to J or to its mirror J^*?



59.4. **The connected sum of oriented submanifolds and knots.** In this section, given two submanifolds $K \subset M$ and $L \subset N$ we introduce the corresponding connected sum $K\#L \subset M\#N$. Eventually our main interest will be in the connected sum of knots $K, L \subset S^3$.

To introduce the connected sum of submanifolds and knots we need to make a few preparations. We recall and expand on some definitions from page 894.

Notation. Let $n \in \mathbb{N}$ and let $k \in \{1, \dots, n-1\}$.

(1) We denote by $\overline{B}_2^n$ and $\overline{B}_2^k$ the closed balls of radius 2 in $\mathbb{R}^n$ and $\mathbb{R}^k$.
(2) We set $J^k := \{(x,0) \in \overline{B}_2^n \,|\, x \in \overline{B}_2^k\}$ and we view equip J^k with the obvious orientation.
(3) Let M be an oriented n-dimensional smooth manifold and let $K \subset M$ be an oriented k-dimensional submanifold. Furthermore let $\varphi\colon \overline{B}_2^n \to M$ be a smooth embedding.
   (a) We say φ respects K if $\varphi(J^k) = \varphi(\overline{B}_2^n) \cap K$, if $\varphi\colon \overline{B}_2^n \to M$ is orientation-preserving and if $\varphi|_{J^k}\colon J^k \to \varphi(\overline{B}_2^n) \cap K$ is orientation-preserving.
   (b) We say φ anti-respects K if the same conditions as in (a) hold, except that we now demand that both maps are orientation-reversing.

In the figure below we illustrate the definition of a map that respects K in the special case that $M = S^3$ and that K is in fact a knot.

The following proposition says that maps that respect a submanifold K always exist and that in a sense they are unique.

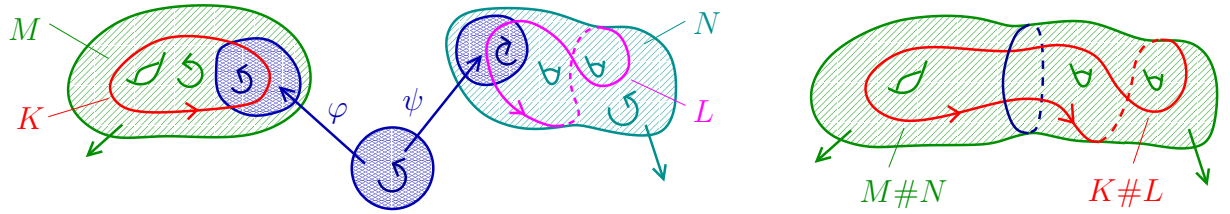
Proposition 59.11. Let M be an oriented n-dimensional smooth manifold. Furthermore let $K \subset M$ be an oriented k-dimensional submanifold.

(1) If K is non-empty, then there exists a map $\varphi\colon \overline{B}_2^n \to M$ that respects K.
(2) If K is connected, then for any two maps $\varphi\colon \overline{B}_2^n \to M$ and $\psi\colon \overline{B}_2^n \to M$ that respect K there exists a diffeotopy $F\colon M \times [0,1] \to M$ such that $F_0 = \mathrm{id}$, such that $F_1 \circ \varphi = \psi$ and such that each $F_t \circ \varphi$ respects K.

The obvious analogues of (1) and (2) also hold for "anti-respect" instead of "respect".

Remark. An analogue of Proposition 59.11 for topological manifolds is proved in [**Liv2021**].

Sketch of proof. The first statement follows easily from the definition of a submanifold. Now let us turn to the proof of the second statement. Thus we assume that K is connected. Let $\varphi\colon \overline{B}_2^n \to M$ and $\psi\colon \overline{B}_2^n \to M$ be two maps that respect K. By Theorem 37.11 there exists a smooth isotopy $I\colon \overline{B}^n \times [0,1] \to M$ such that $I_0 = \varphi$, such that $I_1 = \psi$ and such that each $I_t \circ \varphi$ respects K.



It follows from a slight generalization of the Isotopy Extension Theorem 36.1, see Exercise 37.3, that there exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:

(1) $F_0 = \mathrm{id}$.
(2) For all $x \in \overline{B}^n$ and all $t \in [0,1]$ we have $F(I_0(x), t) = F(x,t)$.

This diffeotopy has all the desired properties. ■

Let us move on to the key definition of this section which can be viewed as a variation on the definition of the connected sum of two oriented smooth manifolds that we gave on page **??**.

Definition. Let M be a closed oriented n-dimensional smooth manifold and let $K \subset M$ be a closed oriented k-dimensional submanifold. Furthermore let N be a closed oriented n-dimensional smooth manifold and let $L \subset N$ be a closed oriented k-dimensional submanifold. We pick a map $\varphi\colon \overline{B}^n_2 \to M$ that respects K and we pick a map $\psi\colon \overline{B}^n_2 \to N$ that anti-respects L. We use $\varphi\colon \overline{B}^n \to M$ and $\psi\colon \overline{B}^n \to N$ to define $M\#N$. Furthermore we use[696] $\overline{B}^k = \overline{B}^k_1 \xrightarrow{x \mapsto (x,0)} J^n_k \xrightarrow{\varphi} K$ and $\overline{B}^k = \overline{B}^k_1 \xrightarrow{x \mapsto (x,0)} J^n_k \xrightarrow{\psi} L$ to define the connected sum $K\#L$ as we did on page **??**. We refer to the resulting pair $(M\#N, K\#L)$ as the connected sum of (M,K) and (N,L).

The following proposition can be viewed as an analogue of the Connected Sum-Proposition **??**.

Proposition 59.12. Let M be a closed oriented n-dimensional smooth manifold and let K be a closed oriented k-dimensional submanifold of M. Furthermore let N be a closed oriented n-dimensional smooth manifold and let L be a closed oriented k-dimensional submanifold of N.

(1) The subset $K\#L$ is a closed k-dimensional smooth submanifold of $M\#N$.
(2) If M and N are both connected, then the oriented diffeomorphism type of the pair $(M\#N, K\#L)$ does not depend on the choice of the map that respects K and the map that anti-respects L.

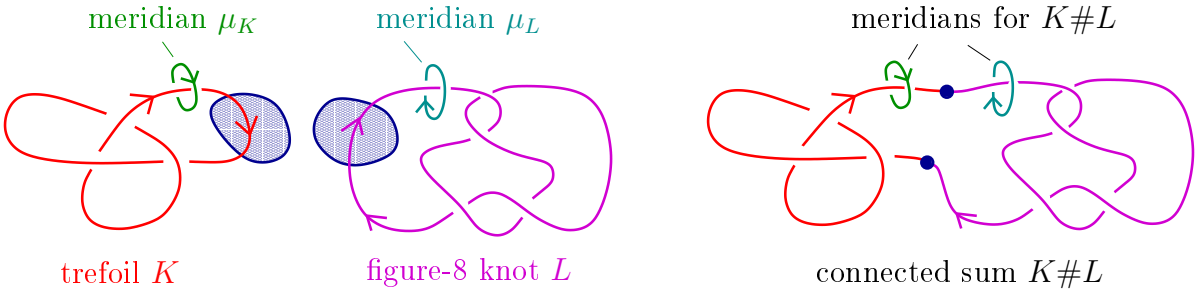
Sketch of proof.

(1) We leave it to the reader to verify this statement. Note that here one needs to make use of the fact that the maps that (anti-) respect the submanifold give us control on $\overline{B}^n_2$ and not just on $\overline{B}^n$.
(2) This statement follows fairly easily from Proposition 59.11. ■

Now we can finally specialize to our beloved setting of knots in S^3. Following most books in knot theory, see e.g. [**Rolf1990**, p. 40] and [**Kaw1996**, p. 30] we introduce the connected sum of two oriented knots as follows:

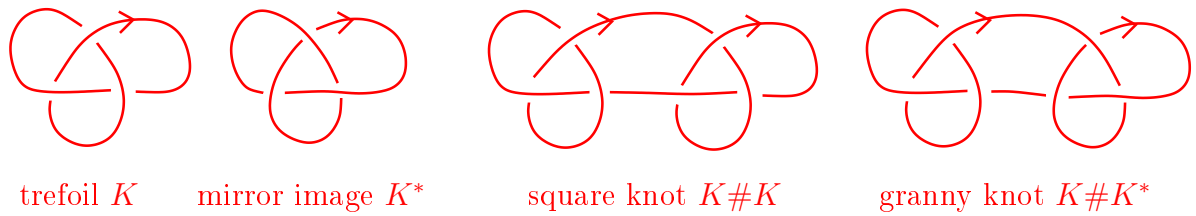
Definition.

(1) Let K and L be two oriented knots in S^3. We pick a map $\varphi\colon \overline{B}^3_2 \to S^3$ that respects K and we pick a map $\psi\colon \overline{B}^3_2 \to S^3$ that anti-respects L. We perform the connected



[696] Note that here we deliberately restrict ourselves from balls of radius 2 to balls of radius 1.

sum $(S^3\#S^3, K\#L)$ and we use the explicit orientation-preserving diffeomorphism $S^3\#S^3 \to S^3$ from Lemma **??** to view $K\#L$ as an oriented knot in S^3.



(2) We say a knot K is prime if it is not smoothly isotopic to the connected sum of two non-trivial knots.

Examples.

(1) In the figure below we show the connected sum of the trefoil K and the figure-8 knot L. Admittedly it can take a minute to connect the picture to the actual definition. Just for fun we also show meridians of K, L and $K\#L$.

(2) In the figure below we show the trefoil and its "mirror image" K^{mir}, i.e. the reflection of K in the xy-hyperplane. The connected sum $K\#K$ is called the *square knot* and the connected sum $K\#K^{\text{mir}}$ is called the *granny knot*. It is notoriously tricky to distinguish the square knot and the granny knot, even up to taking "mirror images".

Proposition 59.13. On the set of smooth isotopy classes of oriented knots the connected sum operation is well-defined and commutative.

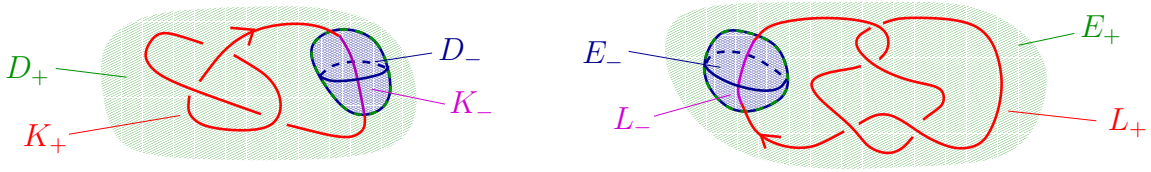
Sketch of proof. First note that it follows almost immediately from the Isotopy Extension Theorem 36.1 together with Proposition 59.12 that the connected sum operation is indeed well-defined.[697] A slight variation on the proof of the Connected Sum-Proposition **??** (5) shows that the connected sum of knots is commutative. ■

But now let us return to our main hobby these days, namely the calculation of fundamental groups. We have the following proposition.

[697] Note though that the statement does not follow just from Proposition 59.12 since we claim that $K\#L$ is well-defined up to isotopy in S^3. This is a priori not the same statement as saying that the oriented diffeomorphism type of $(S^3\#S^3, K\#L)$ is well-defined.

Proposition 59.14. Let K and L be two oriented knots in S^3. We pick meridians μ_K and μ_L and base points $x_0 \in \mu_K$ and $y_0 \in \mu_L$. There exists an isomorphism

$$\pi_1(S^3 \setminus (K\#L)) \;\cong\; \pi_1(S^3 \setminus K, x_0) *_{\langle \mu_K \rangle = \langle \mu_L \rangle} \pi_1(S^3 \setminus L, y_0).$$



given by making the identification $\mu_K = \mu_J$

Sketch of proof. To preserve our sanity we only provide a sketch of the proof. We pick a map $\varphi\colon \overline{B}^3_2 \to S^3$ that respects K and we pick a map $\psi\colon \overline{B}^3_2 \to S^3$ that anti-respects L. We write $D^3_+ := S^3 \setminus \varphi(B^3)$, $D^3_- := \varphi(\overline{B}^3)$ and $K^\pm := D^3_\pm \cap K$. Similarly we write $E^3_+ := S^3 \setminus \psi(B^3)$, $E^3_- := \psi(\overline{B}^3)$ and $L^\pm := E^3_\pm \cap K$. Since all meridians are equivalent we can arrange that $\mu_K \subset \varphi(S^2)$ and that $\mu_L \subset \psi(S^2)$.[698] Now we consider the following diagram

isomorphism by the Seifert–van Kampen Theorem 54.4 for Smooth Manifolds

$$\begin{array}{ccccc} \pi_1(S^3 \setminus K\#L) & = & \pi_1(S^3\#S^3 \setminus K\#L) & \overset{\cong}{\downarrow} & \pi_1(D^3_+ \setminus K_+) *_{\langle \mu_K \rangle = \langle \mu_L \rangle} \pi_1(E^3_+ \setminus L_+) \\ & & & & \downarrow\cong \qquad\qquad \downarrow\cong \\ & & & & \pi_1(S^3 \setminus K) *_{\langle \mu_K \rangle = \langle \mu_L \rangle} \pi_1(S^3 \setminus L). \end{array}$$

Here the vertical maps are isomorphisms by another two applications of the Seifert–van Kampen Theorem 54.4, applied this time to $S^3 \setminus K = (D^3_+ \setminus K_+) \cup (D^3_- \setminus K_-)$ and to $S^3 \setminus L = (E^3_+ \setminus L_+) \cup (E^3_- \setminus L_-)$. Note that here we secretly use the Amalgamated Product Lemma 53.22 (3) twice. ■

Remark. In Section 102.7 we will introduce the "internal connected sum" of two oriented submanifolds. In particular we will introduce the "internal connected sum" of two oriented knots which, for most intents and purposes agrees with the connected sum of two oriented knots.

In Exercise 59.6 we will prove the following corollary to Proposition 59.14.

Corollary 59.15. Let K and L be oriented knots. The fundamental groups of $S^3 \setminus (K\#L)$ and $S^3 \setminus (K\#L^*)$ are isomorphic.

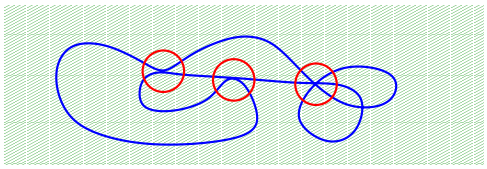
In particular we see that the square knot and the granny knot cannot be distinguished by the fundamental group of their complements. On the other hand we will see in Exercise 149.3 that the granny knot is neither smoothly isotopic to the square knot nor to its mirror image. In particular we see that in general the answer to Question 59.10 is negative.
Fortunately the following deep theorem shows that the situation is much better once we restrict to prime knots. Namely, under this extra hypothesis we actually do get a positive answer to Question 59.10.

[698] Readers who go through the proof with a fine logical comb will notice that the last sentence requires some extra thought.

Theorem 59.16. (Whitten Theorem) Let K and L be two prime knots in $\mathbb{R}^3 \subset \mathbb{R}^3 \cup \{\infty\} = S^3$. If $\pi_1(S^3 \setminus K)$ is isomorphic to $\pi_1(S^3 \setminus L)$, then K is smoothly isotopic to L or to its mirror image L^*.

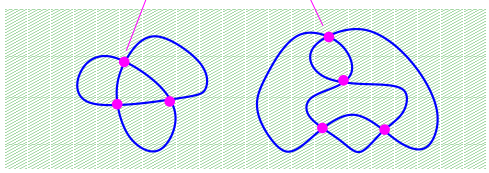
Proof. Let K and L be two prime knots such that the fundamental groups $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus L)$ are isomorphic. Wilbur Whitten [**Whn1987**, Corollary 2.1], building on the Gordon-Luecke Theorem 58.7, showed that there exists a diffeomorphism $F\colon S^3 \to S^3$ with $F(K) = L$. By possibly composing F with the reflection in a hyperplane we see that there exists an orientation-preserving diffeomorphism $F\colon S^3 \to S^3$ with $F(K) = L$ or with $F(K) = L^*$. The claimed statement now follows from Corollary 58.6. ■

59.5. **Knot diagrams.** In the previous section we gave a completely rigorous calculation of the isomorphism type of the fundamental group of the complement of a trefoil and we used this to show that the trefoil is not smoothly isotopic to the trivial knot. In the next section we will give a practical algorithm for determining the isomorphism type of the fundamental group of the complement of a given knot. The key to formulating the algorithm is the notion of a knot diagram that we will study in this section.
Before we start with knot theory we introduce one bit of notation.



Notation. Given a smooth map $f\colon S^1 \to \mathbb{R}^n$ and $z = \exp(\mathrm{i}s) \in S^1$ we write

$f'(z)$:= derivative at the point s of the function $\mathbb{R} \to \mathbb{R}^n$ given by $t \mapsto f(\exp(\mathrm{i}t))$.



Definition. A map $\gamma\colon S^1 \to \mathbb{R}^2$ is called diagrammatic if the following conditions are satisfied:

(a) the map is an immersion,
(b) if $z \neq w \in S^1$ satisfy $\gamma(z) = \gamma(w)$, then $\gamma'(z)$ and $\gamma'(w)$ are linearly independent,
(c) given any $P \in \gamma(S^1)$ the preimage $\gamma^{-1}(P)$ consists of either one or two points.

Furthermore any $z \in S^1$ for which there exists a $w \neq z \in S^1$ with $\gamma(z) = \gamma(w)$ is called a double point of γ.

not allowed in a diagrammatic map

images of diagrammatic maps

Lemma 59.17. Every diagrammatic map has only finitely many double points.

Proof. The lemma will be proved in Exercise 59.4. ■

Definition.

(1) A knot diagram is a diagrammatic map $\gamma\colon S^1 \to \mathbb{R}^2$ together with a map

$$c\colon \{\text{double points of } \gamma\} \to \{\pm 1\}$$

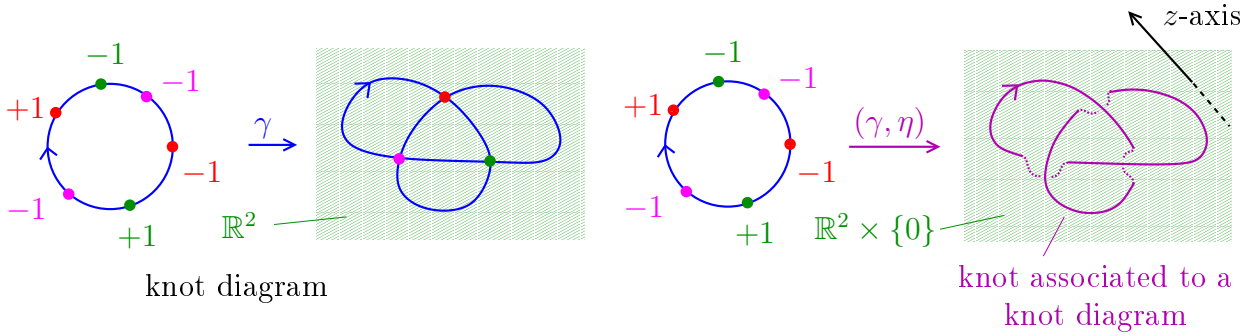
which has the property that for $z \neq w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $c(z) \neq c(w)$.

(2) Let (γ, c) be a knot diagram. Let z be a double point. If $c(z) = +1$, then we say that the double point is an overcrossing, otherwise we call it an undercrossing.

The next lemma shows that knot diagrams give rise to knots.

Lemma 59.18. Let $(\gamma\colon S^1 \to \mathbb{R}^2, c)$ be a knot diagram. We can pick disjoint compact segments $I_1, \ldots, I_k$ of S^1 and a smooth function $\eta\colon S^1 \to [-1, 0]$ with the following properties:

(a) Each segment contains a unique undercrossing and each undercrossing is contained in some segment.
(b) No segment contains an overcrossing.
(c) The value of η outside the segments is equal to 0.
(d) On each segment the function has a unique local minimum, namely at the corresponding undercrossing where the value of η is equal to -1.



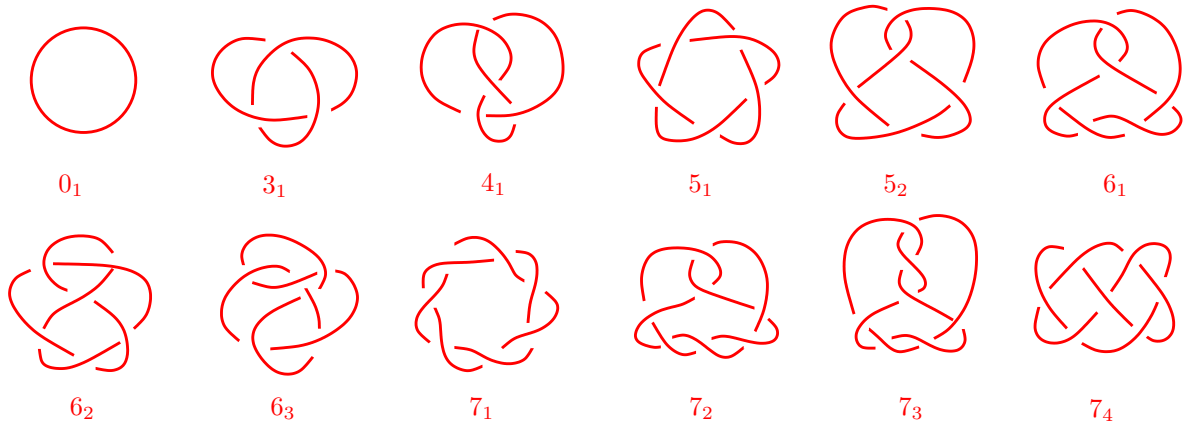
The following two statements hold:

(1) The image of S^1 under the map $S^1 \to \mathbb{R}^3$ given by $z \mapsto (\gamma(z), \eta(z))$ is a knot.
(2) Any two choices of segments and η as above give rise to smoothly isotopic knots.

If we equip S^1 with the standard orientation, then in the above statements we can also replace "knot" by "oriented knot".

Lemma 59.18 shows that a knot diagram gives rise to an essentially unique (oriented) knot. We refer to this knot as the *knot associated to the knot diagram*. At times we will rather blur the difference between a knot diagram and the associated knot.

Example. In the figure below we show to the left a knot diagram. To the right we show the associated knot. It is pretty clear that the resulting knot is smoothly isotopic to the trefoil.



Proof. It follows quite easily from the Smooth Transition Function Lemma 19.4 that such segments $I_1, \ldots, I_k$ and that such a function η exist. Given such a function it is clear that the map $z \mapsto (\gamma(z), \eta(z))$ is injective. Since γ is an immersion it follows that the map $z \mapsto (\gamma(z), \eta(z))$ is in fact a smooth embedding. Thus it follows from the Smooth Embedding Theorem 24.10 (1) that the image is a one-dimensional submanifold of $\mathbb{R}^3 \cup \{\infty\} = S^3$ that is diffeomorphic to S^1. In other words, the image is a knot.

Finally suppose we are given functions η and η' with the properties stated as above. We consider the map

$$\begin{aligned} H\colon S^1 \times [0,1] &\to \mathbb{R}^3 \cup \{\infty\} = S^3 \\ (z, t) &\mapsto (\gamma(z), \eta(z) \cdot (1-t) + \eta'(z) \cdot t). \end{aligned}$$

This map is smooth. By construction we know that for any two distinct points $z, w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $\eta(z) < \eta(w)$ if and only if $c(z) = -1$ if and only if $\eta'(z) < \eta'(w)$. Using this observation one can easily verify that each H_t is a smooth embedding. In other words, the map H_t is a smooth isotopy between the two (oriented) knots corresponding to η and η'. ■

In practice, i.e. in future examples, we do what every other sane topologist does, namely we draw a suggestive picture and we interpret it as a knot diagram and a corresponding knot in the obvious way. For example in the figure below we show the first knots in the standard table of knots. We refer to the standard textbooks on knot theory [**Rolf1990, BZH2014**] for a continuation of the table. But it should already be pretty clear from this table that knots form a straightforward way to produce an almost endless list of interesting topological problems.

In Lemma 59.18 we saw that any knot diagram gives rise to a knot. The following proposition gives us the converse:

Proposition 59.19. (Knot Diagram Existence Proposition) Given any knot $K \subset S^3$ there exists a knot diagram such that K is smoothly isotopic to the knot associated to the knot diagram.

The proof of the Knot Diagram Existence Proposition 59.19 mostly rests on the next lemma. The formulation of this lemma requires the following notation.

Notation. Given $v \in S^2$ we denote by

$$\begin{array}{rccl} \pi_v \colon & \mathbb{R}^3 & \to & v^\perp := \{w \in \mathbb{R}^3 \,|\, \langle v, w\rangle = 0\} \\ & w & \mapsto & w - \langle v, w\rangle v \end{array}$$

the projection onto the orthogonal complement of v.

Now we can formulate the lemma.

Lemma 59.20. Let $K \subset \mathbb{R}^3$ be a knot. We pick a diffeomorphism $f \colon S^1 \to K$. We consider the following three properties of a vector $v \in S^2$:

(a) the map $\pi_v \circ f \colon S^1 \to v^\perp = \{w \in \mathbb{R}^3 \,|\, \langle v, w\rangle = 0\}$ is an immersion,
(b) whenever $z \neq w \in S^1$ satisfy $(\pi_v \circ f)(z) = (\pi_v \circ f)(w)$, then $(\pi_v \circ f)'(z)$ and $(\pi_v \circ f)'(w)$ are linearly independent,

(c) for every $P \in (\pi_v \circ f)(S^1)$ the preimage $(\pi_v \circ f)^{-1}(P)$ consists of either one or two points.

The set
$$\{v \in S^2 \mid v \text{ satisfies (a), (b) and (c)}\}$$
has full measure in S^2.[699]

Remark. Recall that in the Full Measure-Density Proposition 30.3 we showed that a subset of full measure is dense. We leave it to the chronically bored reader to show that the set $\{v \in S^2 \mid v \text{ satisfies (a), (b) and (c)}\}$ considered in Lemma 59.20 is open.

Proof. Let $K \subset \mathbb{R}^3$ be a knot. We pick a diffeomorphism $f\colon S^1 \to K$. We say that a subset of a smooth manifold W is *large* if it is open and if it has full measure in W. It follows from the Measure-Zero Properties Proposition 30.2 that the intersection of two large subsets is again large. Furthermore, it follows from the Measure-Zero Properties Proposition 30.2 that any self-diffeomorphism of S^2 sends large sets to large sets.

It is convenient to consider an extra property of vectors in S^2 which is somewhat weaker than the above property (c):

(c′) given any $P \in (\pi_v \circ f)(S^1)$ the preimage $(\pi_v \circ f)^{-1}(P)$ consists of finitely many points.

We write
$$V(a) \;:=\; \{v \in S^2 \mid v \text{ satisfies (a)}\}.$$
Similarly we define $V(b), V(c), V(a,b), V(a,b,c')$ and so on. Note that with this language we need to show that $V(a,b,c)$ has full measure.

Let $v \in S^2$. We start out with three elementary observations regarding the projections π_v.

(1) Given $u \in \mathbb{R}^3 \setminus \{0\}$ we have
$$\pi_v(u) = 0 \quad\Longleftrightarrow\quad u \in \mathbb{R} \cdot v \quad\Longleftrightarrow\quad \tfrac{u}{\|u\|} \in \{v, -v\}.$$

(2) The projection π_v is linear, hence for any $P \in \mathbb{R}^3$ we have $(\mathrm{D}\pi_v)_P = \pi_v$.

(3) It follows from (2) and the Chain Rule 19.10 that given any $z \in S^1$ we have the equality $(\pi_v \circ f)'(z) = \pi_v(f'(z))$.

Next we consider the three maps[700] [701]
$$\varphi\colon S^1 \to S^2,\quad z \mapsto \tfrac{f'(z)}{\|f'(z)\|} \qquad \psi\colon \overbrace{\{(z,w) \in S^1 \times S^1 \mid z \neq w\}}^{=:M} \to S^2,\quad (z,w) \mapsto \tfrac{f(z)-f(w)}{\|f(z)-f(w)\|} \qquad \text{and} \qquad \rho\colon S^2 \to S^2,\quad v \mapsto -v.$$

[699] We refer to page 762 for the definition of a subset of full measure.

[700] Since f is an immersion we see that the map φ is well-defined, i.e. we do not divide by zero. Similarly, since f is in particular injective we see that the map ψ is well-defined, i.e. once again we do not divide by zero.

[701] The astute reader will notice that throughout the argument it might be more reasonable to work with maps φ and ψ that take values in $\mathbb{R}\mathrm{P}^2 = S^2/x \sim -x$ instead of taking values in S^2. We stick with the maps to S^2 since S^2 has the advantage that its tangent spaces can be described easily as vector subspaces of $\mathbb{R}^3$, which makes it easy to write down differentials. Also, the approach of working with maps to $\mathbb{R}\mathrm{P}^2$ instead creates an extra layer of notation which is as annoying as our notation which requires the extra map ρ.

We make the following observations:

(4) If X is a subset of full measure (respectively large subset) of S^2, then it follows from the above discussion that $X \cap \rho(X)$ is also a subset of full measure (respectively large).
(5) Since f is smooth we see that the map φ is also smooth.
(6) Given $v \in S^2$ it follows easily from (1) and (3) that $\pi_v \circ f \colon S^1 \to \mathbb{R}^2$ is an immersion if and only if neither v nor $-v$ lies in $\varphi(S^1)$. In other words, we have the equality $V(a) = (S^2 \setminus \varphi(S^1)) \cap \rho(S^2 \setminus \varphi(S^1))$.
(7) Note that $M = \{(z,w) \in S^1 \times S^1 \,|\, z \neq w\}$ is an open subset of the smooth manifold $S^1 \times S^1$, thus it is a smooth manifold in an obvious way. With this smooth manifold structure the map $\psi \colon M \to S^2$ is easily seen to be smooth.
(8) For each $(x,y) \in S^1$ we make the identification[702] $\mathrm{T}_{(x,y)}S^1 = \mathbb{R}$ via the basis vector $(-y,x)$. Given $(z,w) \in M$ we use the above identification to make the identification $\mathrm{T}_{(z,w)}M = \mathrm{T}_{(z,w)}(S^1 \times S^1) = \mathbb{R}^2$. Furthermore given $v \in S^2$ we already saw in Lemma 23.1 that we have the equality $\mathrm{T}_v S^2 = v^\perp = \{w \in \mathbb{R}^3 \,|\, \langle v, w\rangle = 0\} \subset \mathbb{R}^3$.
(9) Using the identifications from (8) an elementary calculation[703] shows that for a point $(z,w) \in M$ we can write the differential $\mathrm{D}\psi_{(z,w)}$, viewed as a homomorphism $\mathrm{T}_{(z,w)}M = \mathbb{R}^2 \to \mathrm{T}_{\psi(z,w)}S^2 \subset \mathbb{R}^3$, in the following way as a (3×2)–matrix:

$$\mathrm{D}\psi_{(z,w)} \;=\; \tfrac{1}{\|f(z)-f(w)\|} \cdot \underbrace{\big(\pi_{\psi(z,w)}(f'(z)) \quad -\pi_{\psi(z,w)}(f'(w))\big)}_{(3\times 2)\text{–matrix, in particular two columns}}.$$

(10) It follows from (9) that $(z,w) \in M$ is a regular point of ψ if and only if the vectors $\pi_{\psi(z,w)}(f'(z))$ and $\pi_{\psi(z,w)}(f'(w))$ are linearly independent.
(11) Let $v \in S^2$. It follows immediately from (1) and the linearity of π_v that we have $\pi_v(f(z)) = \pi_v(f(w))$ if and only if $\psi(z,w) = v$ or $\psi(z,w) = -v$.
(12) We denote by $\sigma \colon S^1 \times S^1$ the diffeomorphism given by $(z,w) \mapsto (w,z)$. It follows immediately from the definitions that $\psi \circ \sigma = \rho \circ \psi$.
(13) It follows easily from (3), (10), (11) and (12) that

$$V(b) \;=\; \{\text{regular values of } \psi\}.$$

After these initial remarks we turn to our first claim.

Claim.
(α) The sets $V(a)$ and $V(a,b)$ are large.
(β) We have $V(a) = V(a,c')$ and $V(a,b) = V(a,b,c')$.

Proof. We prove the two statements of the claim in several steps.

(i) Since S^1 is compact we obtain from the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 that $S^2 \setminus \varphi(S^1)$ is an open subset of S^2. Furthermore, since φ is smooth and since $\dim(S^1) < \dim(S^2)$ we obtain from the Full Measure-Density Proposition 30.3 (5) that $S^2 \setminus \varphi(S^1)$ is a subset of full measure. In summary, we

[702] As on many other occasions we use the Tangent Space-Isomorphism Proposition 23.16 to view the tangent space of a submanifold of some $\mathbb{R}^n$ as a vector subspace of $\mathbb{R}^n$.
[703] This calculation can be performed easily using the Chain Rule 19.10 and by writing ψ as the composition of the map $(z,w) \mapsto f(z) - f(w)$ followed by the map $P \mapsto \frac{P}{\|P\|}$.

have shown that $S^2 \setminus \varphi(S^1)$ is large. It follows from (5) and (6) that $V(a) = (S^2 \setminus \varphi(S^1)) \cap \rho(S^2 \setminus (\varphi(S^1)))$ is large.

(ii) It follows from Sard's Theorem 31.1 that the set of regular values of ψ is a subset of full measure. It follows from (i) and (13), together with the Full Measure-Density Proposition 30.3 (1) that $V(a,b) = V(a) \cap V(b)$ has full measure.

(iii) Let $v \in V(a)$. It follows from (11), from the fact that S^1 is compact and from Exercise 24.4 that $\psi^{-1}(v)$ is finite. In particular we see that $V(a,c') = V(a)$ and thus also $V(a,b,c') = V(a,b)$.

(iv) It remains to show that $V(a,b)$ is open. Let $v \in V(a,b) = V(a) \cap V(b)$. From (13) and (iii), together with Lemma 26.2 (2), we obtain an open neighborhood U of $v \in S^2$ that is still contained in $V(b)$. Since $V(a)$ is open we see that $U \cap V(a)$ is an open neighborhood of $v \in S^2$ that is still contained in $V(a,b)$. It follows from the JH-Lemma 1.7 that $V(a,b)$ is indeed open. ⊞

Before we continue it is perhaps helpful to summarize what we have shown so far: In the claim we have seen that $V(a,b,c') = V(a,b)$ is large, in particular that it has full measure. But our actual goal is to show that $V(a,b,c)$ has full measure.

To do so we consider the map

$$\begin{array}{rccc} \Xi\colon & \overbrace{\{(x,y,z) \in S^1 \times S^1 \times S^1 \,|\, x \neq y \text{ and } x \neq z\}}^{=:N} & \to & S^2 \times S^2 \\ & (x,y,z) & \mapsto & (\psi(x,y), \psi(x,z)). \end{array}$$

We make the following simple observations:

(14) We view N as a smooth manifold in an obvious way. Evidently the map Ξ is smooth.

(15) It follows easily from (1) that we have $v \in V(c)$ if and only if none of the four vectors $(\pm v, \pm v)$ lies in $\Xi(N)$.

(16) If one of the four vectors $(\pm v, \pm v)$ lies in $\Xi(N)$, then so does (v,v). This can be seen as follows: If $\Xi(x,y,z) \in \{(\pm v, \pm v)\}$, then $f(x), f(y), f(z)$ lie on the line $\mathbb{R} \cdot v$. After possibly permuting x, y, z we can assume that $f(x) = f(y) + r \cdot v$ and that $f(x) = f(z) + s \cdot v$ with $r, s > 0$. But with this permutation we have $\Xi(x,y,z) = (v,v)$.

Claim. We consider the "partial diagonal"

$$\Delta \;:=\; \{(v,v) \in S^2 \times S^2 \,|\, v \in V(a,b)\}.$$

The complement of $\Xi(N) \cap \Delta$ has full measure in Δ.

Proof. In the previous claim we saw that $V(a,b)$ is an open subset of S^2. Using this fact it is straightforward to see that Δ is a 2-dimensional submanifold of $S^2 \times S^2$. Thus, by Exercise 42.2 (b) it suffices to prove that if $(x,y,z) \in N$ satisfies $\Xi(x,y,z) = (v,v)$ for some $v \in V(a,b)$, then Ξ intersects Δ transversally, i.e. we have the equality

$$(\mathrm{D}\Xi_{(x,y,z)})(\mathrm{T}_{(x,y,z)}N) + \mathrm{T}_{(v,v)}\Delta \;=\; \mathrm{T}_{(v,v)}(S^2 \times S^2) \;\subset\; \mathbb{R}^3 \times \mathbb{R}^3 = \mathbb{R}^6.$$

We write $p = \pi_v(f'(x))$, $q = \pi_v(f'(y))$ and $r = \pi_v(f'(z))$ and we write $\mu = \frac{1}{\|f(x) - f(y)\|}$ and $\nu = \frac{1}{\|f(x) - f(z)\|}$. By (10) and (13), and by the fact that $v \in V(b)$, we know that p, q and r are pairwise linearly independent. In particular q and r form a basis for $\mathrm{T}_v S^2$. Note that this implies that $\begin{pmatrix} q \\ q \end{pmatrix}$ and $\begin{pmatrix} r \\ r \end{pmatrix}$ form a basis for $\mathrm{T}_{(v,v)}(S^2 \times S^2)$. Thus, using (9) we see

that

$$(\mathrm{D}\Xi_{(x,y,z)})(\mathrm{T}_{(x,y,z)}N) + \mathrm{T}_{(v,v)}\Delta \;=\; \text{span of the columns of } \begin{pmatrix} \mu\cdot p & -\mu\cdot q & 0 & q & r \\ \nu\cdot p & 0 & -\nu\cdot r & q & r \end{pmatrix}.$$

Using that p, q and r are pairwise linearly independent it is not hard to see that the five columns of the matrix on the right span a 4-dimensional subspace of $\mathbb{R}^6$. Since this subspace is contained in the 4-dimensional subspace $\mathrm{T}_{(v,v)}(S^2 \times S^2)$ we see that it equals $\mathrm{T}_{(v,v)}(S^2 \times S^2)$. ⊞

We consider the "diagonal map" $d\colon V(a,b) \to \Delta \subset S^2 \times S^2$ that is given by $d(v) = (v, v)$. One can easily show that $d\colon V(a,b) \to \Delta$ is a diffeomorphism. It follows from (16) that $V(a,b,c) = d^{-1}(\Delta \setminus \Xi(N))$. By the claim $\Delta \setminus \Xi(N)$ is a subset of full measure of Δ. Since d is a diffeomorphism we obtain from the Measure-Zero Properties Proposition 30.2 that $V(a,b,c) = d^{-1}(\Delta \setminus \Xi(N))$ has full measure in $V(a,b)$. We saw above that $V(a,b)$ has full measure in S^2. It follows easily from the Measure-Zero Properties Proposition 30.2 that $\Delta \setminus \Xi(N)$ has full measure in S^2. ■

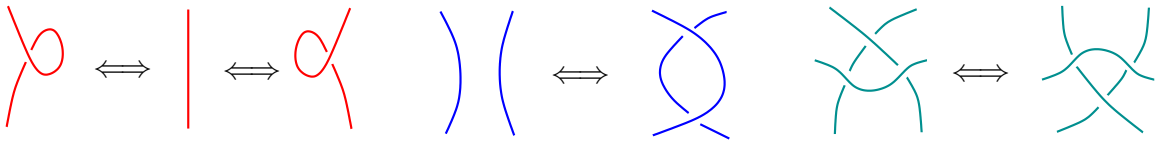
Proof of the Knot Diagram Existence Proposition 59.19. Let $K \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be a knot. As we saw in Exercise **??** (a), it follows easily from the Orthogonal Action Lemma 5.26 (4) and the Diffeotopies-via-Matrices Lemma 33.8 (2) that, possibly after applying a smooth isotopy, we can assume that $K \subset \mathbb{R}^3$.

Next we pick $v \in S^2$ as in Lemma 59.20. It follows from the Orthogonal Action Lemma 5.26 (4) and the Diffeotopies-via-Matrices Lemma 33.8 (2) that, possibly after applying a smooth isotopy, we can assume that $v = e_3$. We define $\gamma := \pi_{e_3} \circ f\colon S^1 \to \mathbb{R}^2 \times \{0\} = \mathbb{R}^2$. It follows immediately from the fact that $v = e_3$ has the three properties (a), (b) and (c) stated in Lemma 59.20 that γ is diagrammatic. Next we consider the function

$$\begin{array}{rcl} \epsilon\colon S^1 & \to & \mathbb{R} \\ w & \mapsto & z\text{-coordinate of } f(w). \end{array}$$

Furthermore, given $z_1 \neq z_2 \in S^1$ with $\gamma(z_1) = \gamma(z_2)$ we define

$$c(z_i) \;:=\; \begin{cases} +1, & \text{if } \epsilon(z_i) > \epsilon(z_{3-i}), \\ -1, & \text{if } \epsilon(z_i) < \epsilon(z_{3-i}). \end{cases}$$



It is clear that (γ, c) is a knot diagram. We pick a function $\eta\colon S^1 \to [-1, 0]$ as in Lemma 59.18. We consider the map

$$\begin{array}{rcl} H\colon S^1 \times [0,1] & \to & \mathbb{R}^3 \\ (z,t) & \mapsto & (\gamma(z), (1-t)\cdot\epsilon(t) + t\cdot\eta(t)). \end{array}$$

Clearly this map is smooth. Given any $z, w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $\eta(z) < \eta(w)$ if and only if $c(z) = -1$ if and only if $\eta(z) < \eta(w)$. From this observation we deduce that each H_t is actually a smooth embedding. Thus we see that H is a smooth isotopy from K to the knot associated to the knot diagram (γ, η). ■

We have now seen that every knot, up to smooth isotopy, arises from a knot diagram. The question arises, when do two knot diagrams give rise to smoothly isotopic knots. The following theorem gives a complete answer. We formulate the theorem in a slightly informal way since we will not make use of it.

Theorem 59.21. (Reidemeister Moves Theorem) Two knot diagrams give rise to smoothly isotopic knots if and only if the two diagrams are related by a finite sequence of smooth isotopies of $\mathbb{R}^2$ and Reidemeister moves. The three Reidemeister moves are illustrated in the figure below.

Reidemeister move 1 Reidemeister move 2 Reidemeister move 3

Proof. The theorem, not surprisingly, goes back to work of Kurt Reidemeister [**Rei1932**, Chapter 3] in 1932. The formulation and proof in [**Rei1932**] is in terms of "polygonal knots". The statement of the theorem is well known in our setting, where knots are defined as submanifolds of S^3 and it appears in any textbook on knot theory. A satisfactory proof can be found in [**OSS2015**, Theorem B.1.1]. ■

Remark. Throughout these lecture notes we will see on several occasions that the tools of algebraic topology, e.g. fundamental groups, linking pairings and Reidemeister torsion can be used fruitfully to study knots. the Knot Diagram Existence Proposition 59.19 and the Reidemeister Moves Theorem 59.21 open up an alternative route to studying knots. More precisely, these two results show that there exists a bijection

$$\begin{array}{c}\text{knot diagrams up to smooth isotopy}\\ \text{and Reidemeister moves}\end{array} \xrightarrow{\cong} \text{knots up to smooth isotopy}$$

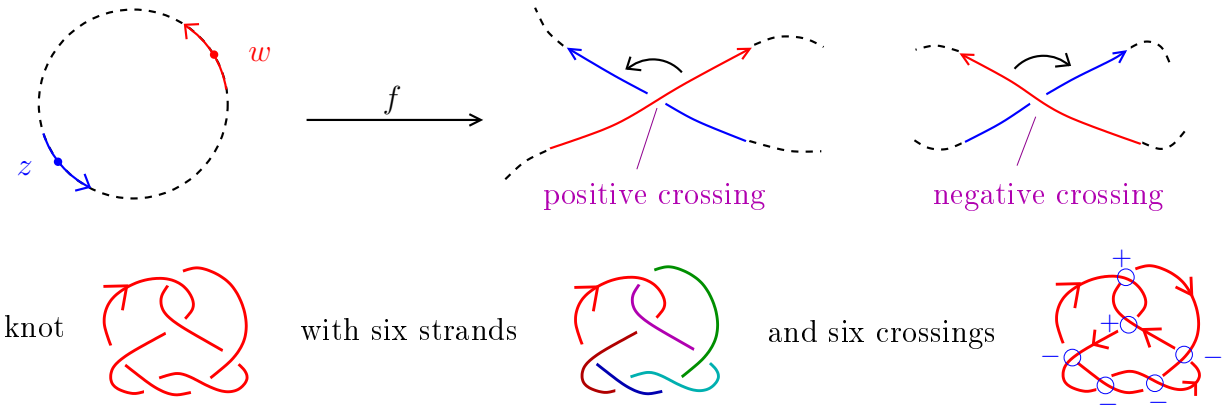
This bijection lies at the heart of the definition of several knot invariants, like the Jones polynomial [**JonV1985**] that was introduced in 1984 and the HOMFLY-PT polynomial [**FYHLMO1985, PT1987**] that was discovered in 1985. These polynomial invariants are quite different from any of the invariants that are obtained through algebraic-topological methods. We refer to [**Lic1997a**, Chapters 3 and 15] and [**BZH2014**, Chapter 17] for more information on these invariants.

59.6. **The Wirtinger presentation.** In the previous section we saw that we can associate a knot diagram to any given knot. In this section we will see that we give an explicit algorithm that, given a knot diagram, produces a presentation for the fundamental group of the complement $S^3 \setminus K$ of a knot K.

In this section we will take several liberties and we will not attempt to give full details in the proofs. The issue is that any attempt to make the proofs completely rigorous renders them totally unreadable.

Before we can state the promised algorithm we need to introduce a few more definitions.

Definition. Let $K \subset \mathbb{R}^3$ be an oriented knot that is associated to some knot diagram $(f\colon S^1 \to \mathbb{R}^2, c)$.



(1) We refer to the images of the double points as the crossings of K.
(2) Let $x \in f(S^1)$ be a crossing. Let $z, w \in S^1$ with $f(z) = f(w) = x$ and such that z is an undercrossing and w is an overcrossing. We say x is a positive crossing if the

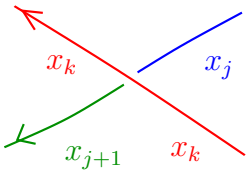
ordered basis $\{f'(w), f'(z)\}$ is a positive basis for $\mathbb{R}^2$. Otherwise we say that x is a negative crossing.

(3) We refer to the components of $K \cap (\mathbb{R}^2 \times \{0\})$ as the strands of K.

These definitions are illustrated in the figures below.

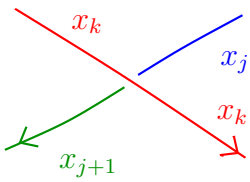
Remark. In a picture of a diagram the strands are understood to correspond precisely to the segments drawn.

The following lemma will be proved in Exercise 59.8.



Lemma 59.22. If a knot diagram has at least one crossing, then the number of crossings equals the number of strands.

The following proposition shows how to determine the fundamental group of a knot that is associated to a knot diagram. We will sacrifice some rigor in the formulation in an attempt to make it more readable. We leave it to the reader to make the proposition totally rigorous.

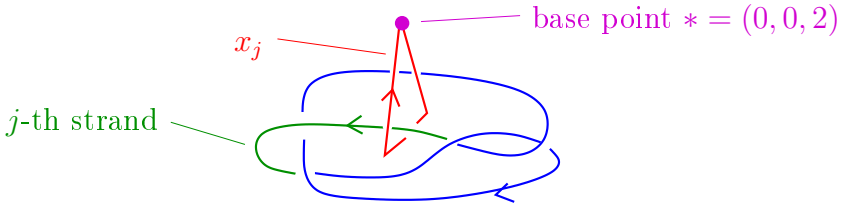


Proposition 59.23. (Wirtinger Presentation Proposition) Let K be a knot that is associated to a given knot diagram that has at least one crossing. We enumerate the strands cyclically by $x_1, \ldots, x_n$ where we make the identifications $x_0 = x_n$ and $x_{n+1} = x_1$. For the crossing between the strands x_j and x_{j+1} we define a relation r_j as shown in the figure below. Then we have an isomorphism

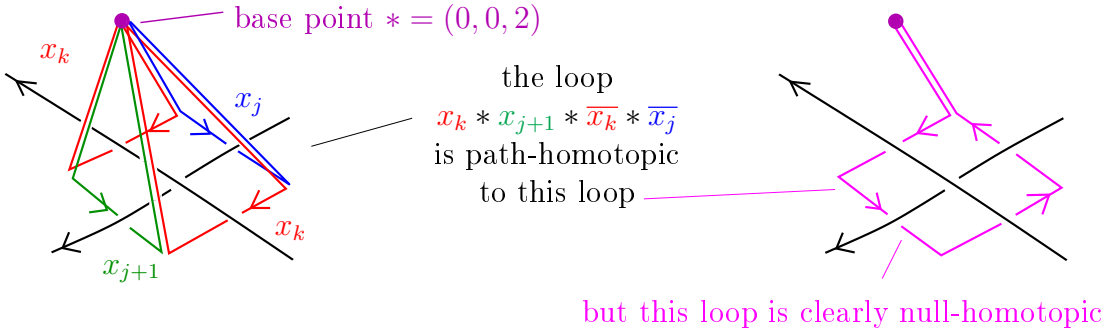
$$\pi_1(S^3 \setminus K) \;\cong\; \langle x_1, \ldots, x_n \,|\, r_1, \ldots, r_n \rangle.$$

Furthermore we can drop any one of the relations and we still obtain an isomorphism.

the positive crossing gives rise to the relation $r_j = x_k \cdot x_{j+1} \cdot x_k^{-1} \cdot x_j^{-1}$



the negative crossing gives rise to the relation $r_j = x_k^{-1} \cdot x_{j+1} \cdot x_k \cdot x_j^{-1}$



Remark. Given a knot K, any presentation with n generators and $n-1$ relators as obtained from the Wirtinger Presentation Proposition 59.23 is called a *Wirtinger presentation of* $\pi_1(S^3 \setminus K)$.

In the following we first explain why the Wirtinger Presentation Proposition 59.23 is plausible. Afterwards we will provide the technical proof of the Wirtinger Presentation Proposition 59.23.

Proof. "Plausibility argument for the Wirtinger Presentation Proposition 59.23"] Suppose we are given a knot diagram that has n crossings. We denote by K the corresponding knot. We work with the base point $* = (0, 0, 2) \in \mathbb{R}^3$ which lies "above" the knot K. We enumerate the strands cyclically. For the j-th strand we denote by x_j the oriented triangle that starts at $*$ and "circles once around the j-th strand" according to the "right-hand rule". We illustrate the definition in the figure below.

Next we consider the situation at a positive crossing. By "sliding" various x_j along the strands and by some further path-homotopies we can assume that we are in the situation in the figure below on the left. If one follows the loop $x_k * x_{j+1} * \overline{x_k} * \overline{x_j}$ on its journey one realizes that on three occasions one goes back and forth to the base point. Thus the loop is actually path-homotopic to the loop shown in the figure below on the right. But that loop is clearly null-homotopic. Almost the same logic applies to negative crossings.

This discussion, together with Lemmas 51.15 and 53.4, shows that there exists a unique group homomorphism

$$\begin{array}{rcl} \langle x_1, \ldots, x_n \,|\, \text{relations corresponding to crossings} \rangle & \to & \pi_1(S^3 \setminus K, *) \\ x_i & \mapsto & [x_i]. \end{array}$$

with

It remains to show that this group homomorphism is in fact an isomorphism. We will do so next in the proper proof of the Wirtinger Presentation Proposition 59.23. ■

Sketch of a proof for the Wirtinger Presentation Proposition 59.23. Suppose once again that we are given a knot diagram $(\gamma\colon S^1 \to \mathbb{R}^2, c)$ that has $n \geq 1$ crossings. We denote by $P_1, \ldots, P_n$ the double points of γ. We pick a smooth function $\eta\colon S^1 \to [-1, 0]$ as

in the statement of Lemma 59.18. We denote by K the image of the map $S^1 \to \mathbb{R}^3$ given by $z \mapsto (\gamma(z), \eta(z))$. It follows from property (d) of Lemma 59.18 that

$$K \cap (\mathbb{R}^2 \times \mathbb{R}_{\leq -1}) \;=\; K \cap (\mathbb{R}^2 \times \{-1\}) \;=\; \{(P_1, -1), \ldots, (P_n, -1)\}.$$

In contrast to the above plausibility argument we now actually work with the base point $\infty \in S^3 = \mathbb{R}^3 \cup \{\infty\}$. We set

$$A \;:=\; (\{(x, y, z) \in \mathbb{R}^3 \,|\, z \geq -1\} \cup \{\infty\}) \setminus K,$$

and

$$B \;:=\; (\{(x, y, z) \in \mathbb{R}^3 \,|\, z \leq -1\} \cup \{\infty\}) \setminus K.$$

We start out with the following claim.

Claim 1. The inclusion maps induce an isomorphism

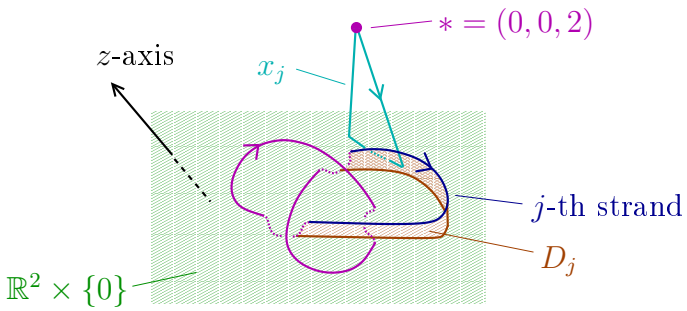
$$\pi_1(A, \infty) *_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty) \;\cong\; \pi_1(S^3 \setminus K).$$

Proof. Evidently the statement of the claim smells like it should be a consequence of the Seifert–van Kampen 54.1. The problem is that A and B are not open subsets of $S^3 \setminus K$. We rectify this problem by replacing A and B by suitable open subsets. We define

$$\begin{aligned} U \;&:=\; A \;\cup\; (\mathbb{R}^2 \setminus \{P_1, \ldots, P_n\}) \times (-2, -1) \\ \text{and} \qquad V \;&:=\; B \;\cup\; (\mathbb{R}^2 \setminus \gamma(S^1)) \times [-1, 0) \\ &\qquad\; \cup\; \{(z, t) \,|\, \text{ there exists } w \in S^1 \text{ with } z = \gamma(w) \text{ and } t \in [-1, \eta(z))\}. \end{aligned}$$

One can easily verify that U and V are open subsets of $S^3 \setminus K$. Furthermore the "obvious retractions" of the blue sets to the corresponding subsets of $\mathbb{R}^2 \times \{-1\}$ show that A is a deformation retract of U, that B is a deformation retract of V and that $A \cap B$ is a deformation retract of $U \cap V$. Now we see that the inclusion maps induce isomorphisms

$$\pi_1(S^3 \setminus K) \;\overset{\cong}{\underset{\uparrow}{\leftarrow}}\; \pi_1(U, \infty) *_{\pi_1(U \cap V, \infty)} \pi_1(V, \infty) \;\overset{\cong}{\underset{\uparrow}{\rightarrow}}\; \pi_1(A, \infty) *_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty).$$



by the Seifert–van Kampen Theorem 54.1

by the above, the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2) ⊞

Our next goal is to understand the groups $\pi_1(A, \infty)$, $\pi_1(B, \infty)$ and $\pi_1(A \cap B, \infty)$. We handle these three groups consecutively. To better understand $\pi_1(A, \infty)$ we introduce the following objects.

(1) As in the plausibility argument we set $* = (0, 0, 2)$. We fix once and for all a path-connecting $*$ to ∞.
(2) We write $D := \{(\gamma(z), w) \,|\, z \in S^1 \text{ and } w \in [-1, \eta(z))\}$.
(3) We cyclically enumerate the strands of the knot.
(4) For $j \in \{1, \ldots, n\}$ we denote by D_j the unique component of D that contains the j-th strand in its closure.
(5) For $j = 1, \ldots, n$ we denote by x_j a loop in $*$ that is the boundary of a triangle that intersects D_j precisely once in a positive[704] direction. We use the path from (1) to view each x_j as a loop in ∞.

[704]Here by "positive direction" we mean that the orientation vectors of the triangle followed by the orientation vector of the knot should form a positive basis for $\mathbb{R}^3$.

Claim 2. The obvious map $\langle x_1, \dots, x_n \rangle \to \pi_1(A, \infty)$ is an isomorphism.

Proof. Note that each D_j is contractible and hence simply connected. Furthermore one can easily show that $A \setminus D$ is contractible. We use Corollary 57.5 iteratively n times to prove the claim. We leave it to the assiduous reader to fill in the details.[705] ⊞

Fortunately the next group $\pi_1(B, \infty)$ on our list is easy to handle.

Claim 3. The group $\pi_1(B, \infty)$ is trivial.

Proof. Using the stereographic projection from Lemma 2.18 and using the map defined on page 152 it is not hard to see that there exists a homeomorphism

$$f \colon (\{(x,y,z) \in \mathbb{R}^3 \,|\, z \leq -1\} \cup \{\infty\} \;\to\; \overline{B}^3$$

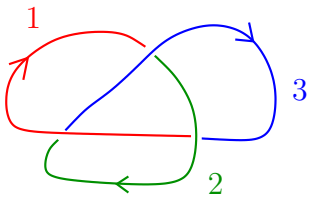
which sends the points in $\mathbb{R}^2 \times \{-1\}$ to S^2. Since $K \cap (\mathbb{R}^2 \times \mathbb{R}_{\leq -1}) = \{(P_1, -1), \dots, (P_n, -1)\}$ we see that B is homeomorphic to $\overline{B}^3$ with n points on its boundary removed. But this does not change the fact that the origin is a deformation retract. We have thus shown that $f(B)$, and hence also B, is contractible. But this implies by the Homotopy-π_1-Proposition 50.3 (3) that $\pi_1(B, \infty)$ is indeed trivial. ⊞

Finally we turn to the group $\pi_1(A \cap B, \infty)$. We pick orientation-preserving smooth embeddings $\varphi_i \colon \overline{B}^2 \to \mathbb{R}^2 \times \{-1\}$, $i = 1, \dots, n$ with disjoint images and such that for each i we have $\varphi_i(0) = (P_i, -1)$. It follows almost immediately[706] from Lemma 57.6 that we have an equality

$$\langle z_1, \dots, z_n \mid z_1 \cdot \dots \cdot z_n \rangle \;=\; \pi_1(A \cap B, \infty)$$

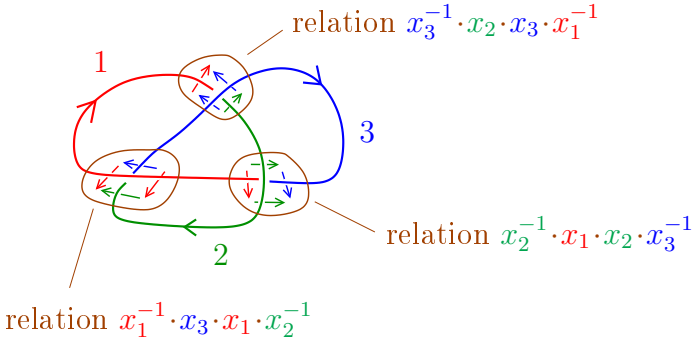
where for any $i \in \{1, \dots, n\}$ the element z_i is represented by a curve of the form $\alpha_i * \gamma_i * \overline{\alpha}_i$ where α_i is a suitable path from ∞ to a point on $\varphi_i(S^1)$ and γ_i is a path that goes once around $\varphi_i(S^1)$ in an orientation-preserving way.

[705] The details involve replacing the set D_j by a suitable open subset to be able to apply Corollary 57.5.



[706] The slightly cautious "almost" refers to the fact that we also make use of the fairly obvious fact that $((\mathbb{R}^2 \times \{-1\}) \cup \{\infty\}) \setminus \bigcup_{i=1}^{n} \varphi_i(B^2)$ is a deformation retract of $A \cap B = ((\mathbb{R}^2 \times \{-1\}) \cup \{\infty\}) \setminus \{P_1, \dots, P_n\}$.

Now we can finally prove the desired statement. Indeed, we have



$$\begin{array}{ccccc}
\pi_1(S^3 \setminus K) & \cong & \pi_1(A,\infty) *_{\pi_1(A\cap B,\infty)} \pi_1(B,\infty) & \cong & \pi_1(A,\infty)/\langle\langle \pi_1(A\cap B,\infty)\rangle\rangle \\
& \uparrow & & \uparrow & \\
& \text{by Claim 1} & & \text{by Claim 3 and the Amalgamated Product Lemma 53.22 (2)} & \\
& \cong & \langle x_1,\dots,x_n\rangle/\langle\langle z_1,\dots,z_n\rangle\rangle & \cong & \langle x_1,\dots,x_n\rangle/\langle\langle r_1,\dots,r_n\rangle\rangle. \\
& \uparrow & & \uparrow & \\
& \text{by Claim 2, Lemma 53.2 (4) and the above fact that } \{z_1,\dots,z_n\} \text{ is a generating set for } \pi_1(A\cap B,\infty) & & \text{“plausibility argument shows that each } z_i \text{ is conjugate to } r_i, \text{ thus it follows from Lemma 53.2 (5) that } \langle\langle z_1,\dots,z_n\rangle\rangle = \langle\langle r_1,\dots,r_n\rangle\rangle &
\end{array}$$

It remains to show that we can drop any one of the relations. Thus let $j \in \{1,\dots,n\}$. It follows easily from $z_1 \cdot \dots \cdot z_n = e$ that $z_j \in \langle z_1,\dots,z_{j-1},z_{j+1},\dots,z_n\rangle$. Now note that by Lemma 53.2 (4) this implies that $\langle\langle z_1,\dots,z_n\rangle\rangle = \langle\langle z_1,\dots,z_{j-1},z_{j+1},\dots,z_n\rangle\rangle$. Therefore we see that in the above equality we can drop the relation r_j. ■

As mentioned above, we continue with two examples, namely the trefoil and the figure-8 knot. First we consider the knot diagram for the trefoil K that is shown in the figure below to the left. We number the strands as shown. To the right we show how the three crossings give rise to three relations. As pointed out in the Wirtinger Presentation Proposition 59.23, we can drop any one of the relations.

knot diagram for the trefoil
with three negative crossings

This discussion shows that we have proved the following lemma.

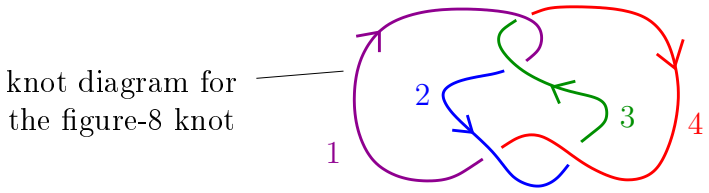
Lemma 59.24. Let K be the trefoil. There exists an isomorphism

$$\pi_1(S^3 \setminus K) \cong \langle x_1,x_2,x_3 \,|\, x_3^{-1}x_2x_3x_1^{-1}, x_2^{-1}x_1x_2x_3^{-1}\rangle.$$

Remark. Let K be the trefoil. In Proposition 59.5 we had also shown that there exists an isomorphism $\pi_1(S^3 \setminus K) \cong \langle x,y \mid x^2 = y^3\rangle$. In particular we have now shown that the two groups $\langle x_1,x_2,x_3 \,|\, x_3^{-1}x_2x_3x_1^{-1}, x_2^{-1}x_1x_2x_3^{-1}\rangle$ and $\langle x,y \mid x^2 = y^3\rangle$ are isomorphisms. In Exercise 59.9 we will give a purely algebraic proof of this statement.

The following corollary to the Wirtinger Presentation Proposition 59.23 gives us the disappointing news that our old trick of using abelianizations of fundamental groups cannot be used to distinguish knots.

Corollary 59.25. (Knot Group-Abelianization Corollary) Given any knot K the abelianization of the group $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.



Proof. We will prove the corollary in Exercise 59.5. Later, on page 1836, once we have introduced homology groups we will give a different, arguably more conceptual proof of the lemma. ■

After this sobering corollary we move on to the next example.

Lemma 59.26. Let J be the figure-8 knot. There exists an isomorphism

$$\pi_1(S^3 \setminus J) \;\cong\; \langle x_1, x_2, x_3, x_4 \,|\, x_3 x_2 x_3^{-1} x_1^{-1}, x_4^{-1} x_3 x_4 x_2^{-1}, x_1 x_4 x_1^{-1} x_3^{-1} \rangle.$$

Proof. We leave it to the reader to use the knot diagram shown in the figure below to prove the lemma. ■

On its own Lemma 59.26 is not particularly enlightening. It is initially not clear whether this group is isomorphic to $\mathbb{Z}$ or to the fundamental group of the complement of the trefoil. By the Knot Group-Abelianization Corollary 59.25 we know that there is no hope that the abelianization will tell us something interesting.

So we need a different approach. Recall that in Proposition 59.6 we used the (non-) existence of an epimorphism onto the symmetric group S_3 to distinguish the trefoil from the trivial knot. The idea now is to repeat this trick with a different finite group. Recall that on page 1127 we introduced the dihedral groups D_n which have $2n$ elements. It is encouraging that $D_3 \cong S_3$ thus we try our luck with D_5.[707]

Using Lemma 53.13 and enough time on our hands we obtain the following table:

	trivial knot	trefoil	figure-8 knot
epimorphism onto S_3	✗	✓	✗
epimorphism onto the dihedral group D_5	✗	✗	✓

This table shows that we have proved the following corollary.

Corollary 59.27. The trivial knot, the trefoil and the figure-8 knot are pairwise not smoothly isotopic.

This approach of trying to distinguish knots by the (non-) existence of epimorphisms onto finite groups is rather ad hoc, but not without its merits. For example the following proposition is proved in [**BF2020, BR2020**].

Proposition 59.28. Let K be either the trivial knot, the trefoil or the figure-8 knot. Furthermore let J be another knot. If for all finite groups G the group $\pi_1(S^3 \setminus K)$ admits an epimorphism onto G if and only if $\pi_1(S^3 \setminus J)$ does, then J is smoothly isotopic to K or to the mirror image of K, i.e. the reflection of K in the xy-plane.

We conclude this section with the following question which is still open.

Question 59.29. Let K and J be two knots in $\mathbb{R}^3 \subset \mathbb{R}^3 \cup \{\infty\} = S^3$. Suppose that the finite groups onto which $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus J)$ admit epimorphisms are the same. Does this imply that K and J are smoothly isotopic, up to possibly taking a reflection in the xy-plane?

[707] The reader might ask, why we do not try our luck with D_4. But for reasons we cannot get into right now, given a knot K and an even number $2n$ there cannot be an epimorphism $\pi_1(S^3 \setminus K) \to D_{2n}$.

59.7. **The Reidemeister-Schreier process.** Even though the Knot Group-Abelianization Corollary 59.25 was quite disappointing, using a clever jiu-jitsu move we will see in this section that we can actually turn the Knot Group-Abelianization Corollary 59.25 to our advantage. The key to doing so is contained in the following definition and the subsequent lemma.

Definition. Let π be a group and let $n \in \mathbb{N}$. We say that a subgroup $\Gamma \subset \pi$ is cocyclic of order n if Γ is a normal subgroup such that π/Γ is isomorphic to $\mathbb{Z}_n$.

Lemma 59.30. If π is a group whose abelianization is isomorphic to $\mathbb{Z}$, then given any $n \in \mathbb{N}$ there exists a unique subgroup that is cocyclic of order n. It is given by the kernel of any epimorphism $\pi \to \mathbb{Z}_n$.

Proof. Let π be a group whose abelianization is isomorphic to $\mathbb{Z}$ and let $n \in \mathbb{N}$. We denote by $\psi\colon \pi \to \pi_{\text{ab}}$ the natural projection and we pick an isomorphism $\varphi\colon \pi_{\text{ab}} \xrightarrow{\cong} \mathbb{Z}$. It is clear that $(\varphi \circ \psi)^{-1}(n\mathbb{Z})$ is a subgroup of π that is cocyclic of order n. On the other hand, suppose that Γ is a subgroup of π that is cocyclic of order n. We pick an isomorphism $\theta\colon \pi/\Gamma \cong \mathbb{Z}_n$. It follows from the Abelianization Proposition 53.20 that there exists a unique epimorphism $\alpha\colon \mathbb{Z} \to \mathbb{Z}_n$ such that the following diagram commutes:

$$\begin{array}{ccccc} \pi & \xrightarrow[\cong]{\psi} & \pi_{\text{ab}} & \xrightarrow[\cong]{\varphi} & \mathbb{Z} \\ {\scriptstyle g\mapsto g\Gamma}\big\downarrow & & & & \big\downarrow{\scriptstyle \alpha} \\ \pi/\Gamma & & \xrightarrow[\cong]{\theta} & & \mathbb{Z}_n. \end{array}$$

It follows immediately that $\Gamma = (\varphi \circ \psi)^{-1}(n\mathbb{Z})$. ∎

The Knot Group-Abelianization Corollary 59.25 and Lemma 59.30 allow us to make the following definition.

Definition. Given a knot K and $n \in \mathbb{N}$ we denote by $\pi(K, n)$ the unique subgroup of $\pi_1(S^3 \setminus K)$ that is cocyclic of order n.

Example. If K is the trivial knot, then we saw in Proposition 59.4 that we can make an identification $\pi_1(S^3 \setminus K) = \mathbb{Z}$. It follows easily that for any $n \in \mathbb{N}$ we have $\pi(K, n) = n \cdot \mathbb{Z}$, in particular $\pi(K, n)$ is isomorphic to $\mathbb{Z}$.

We have now a new tool for trying to distinguish knots:

Lemma 59.31. Let K and J be two knots. If K and J are smoothly isotopic, then given any $n \in \mathbb{N}$ the groups $\pi(K, n)$ and $\pi(J, n)$ are isomorphic. In particular the abelianizations of these groups are isomorphic.

The question arises, given a knot K and $n \in \mathbb{N}$, how can we determine $\pi(K, n)$ from a given presentation for $\pi_1(S^3 \setminus K)$? Fortunately the following proposition gives us an explicit algorithm. To facilitate the uptake we formulate the following proposition in a slightly informal way.

Proposition 59.32. (Reidemeister-Schreier Process) Let $\pi = \langle x_1, \dots, x_m, t \,|\, r_1, \dots, r_l \rangle$ be a group and let $\phi\colon \pi \to \mathbb{Z}_n$ be an epimorphism such that $\phi(x_1) = \cdots = \phi(x_m) = 0$ and

$\phi(t) = 1$. Then a presentation for the subgroup $\ker(\phi\colon \pi \to \mathbb{Z}_n)$ is given by

$$\langle y_{1,0}, \dots, y_{1,n-1}, \dots, y_{m,0}, \dots, y_{m,n-1}, u \,|\, s_1^0, \dots, s_1^{n-1}, \dots, s_l^0, \dots, s_l^{n-1} \rangle$$

where each s_i^j is obtained as follows:

(1) For $i = 1, \dots, l$ and $j = 0, \dots, n-1$ we write $t^j r_i t^{-j}$ as an expression in

$$x_1, tx_1t^{-1}, \dots, t^{n-1}x_1t^{-n+1}, \dots, x_m, tx_mt^{-1}, \dots, t^{n-1}x_mt^{-n+1} \text{ and } t^n.$$

(2) Then we replace each term $t^j x_i t^{-j}$ by $y_{i,j}$ and we replace t^n by u. We obtain a word in the new generators and denote it by s_i^j.

The inclusion map $\ker(\phi\colon \pi \to \mathbb{Z}_n) \to \pi$ is then given by sending each $y_{i,j}$ to $t^j x_i t^{-j}$ and by sending u to t^n.

Proof. As we had mentioned above, the proposition follows fairly easily from the more general Reidemeister-Schreier process that is explained in [**LyS1977**, Chapter II.4], [**MKS1976**, Chapter 2.3] or [**Bog2008**, Chapter 2.9]. ■

Instead of studying the proof of Proposition 59.32 our time is better spent trying to understand two explicit examples.

Example. Let $K \subset S^3$ be the trefoil. We write $\pi = \pi_1(S^3 \setminus K)$. In Proposition 59.5 we showed that we can make the identification $\pi = \langle x, t \mid \underbrace{x^3 \cdot t^{-2}}_{=r} \rangle$. By Lemma 53.13 there exists a unique epimorphism $\phi\colon \pi \to \mathbb{Z}_2$ with $\phi(x) = 0$ and $\phi(t) = 1$. Evidently $\pi(K, 2) = \ker(\phi\colon \pi \to \mathbb{Z}_2)$. Now we will use Proposition 59.32 to find a presentation $\langle y_0, y_1, u \,|\, s_0, s_1 \rangle$ for $\ker(\phi\colon \pi \to \mathbb{Z}_2)$. We write

$t^0 r t^{-0} = \underbrace{x^3}_{=y_0^3} \cdot \underbrace{t^{-2}}_{=u^{-1}}$ and more interestingly $t^1 r t^{-1} = t x^3 t^{-3} = (txt^{-1})^3 \cdot t^{-2} = \underbrace{(txt^{-1})}_{y_1}^3 \cdot \underbrace{t^{-2}}_{=u^{-1}}$.

Thus we see that

$$\pi(K,2) \;=\; \ker(\phi\colon \pi \to \mathbb{Z}_2) \;\underset{\text{Proposition 59.32}}{=}\; \langle y_0, y_1, u \,|\, y_0^3 u^{-1}, y_1^3 u^{-1} \rangle \;\underset{\text{by the Tietze transformations from page 1196}}{=}\; \langle y_0, y_1 \,|\, y_0^3 = y_1^3 \rangle.$$

Using the Abelianization Proposition 53.20 we can now easily compute that the abelianization of the above group $\pi(K, 2) = \ker(\phi\colon \pi \to \mathbb{Z}_2)$ is isomorphic to $\mathbb{Z} \oplus \mathbb{Z}_3$.

This calculation, together with Lemma 59.31 and the above discussion of the trivial knot, gives a new proof of Proposition 59.6.

The previous example was fairly straightforward since we had started out with a presentation where one generator got sent to one, and the other ones got sent to zero. Unfortunately this is not the case for Wirtinger presentations, so we will need to work somewhat harder. In the following example we consider the figure-8 knot K and we carry out the first steps needed to calculate the isomorphism type of $\pi(K, 2)$.

Example. Let J be the figure-8 knot. In Lemma 59.26 we saw that we can make the identification

$$\pi_1(S^3 \setminus J) \;=\; \langle y_1, y_2, y_3, y_4 \,|\, y_1^{-1} y_4 y_1 y_3^{-1}, y_3^{-1} y_2 y_3 y_1^{-1}, y_2^{-1} y_1 y_2 y_4^{-1} \rangle.$$

We denote by $\phi\colon \pi_1(S^3 \setminus J) \to \mathbb{Z}_2$ the epimorphism that is given by sending each y_i to 1. We set $t := y_1$. The goal is to replace the generators y_1, y_2, y_3 by generators x_1, x_2, x_3 which

satisfy $\phi(x_i) = 0$. In fact we have

$$\begin{aligned}\pi_1(S^3 \setminus J) &= \langle t, y_2, y_3, y_4 \,|\, t^{-1}y_4 t y_3^{-1}, y_3^{-1}y_2y_3t^{-1}, y_2^{-1}ty_2y_4^{-1}\rangle \\ &= \langle t, y_2, y_3, y_4 \,|\, \underbrace{t^{-1}y_4t^{-1}tty_3^{-1}}_{=t^{-1}y_4ty_3^{-1}}, \underbrace{t^{-1}ty_3^{-1}y_2t^{-1}ty_3t^{-1}}_{=y_3^{-1}y_2y_3t^{-1}}, \underbrace{t^{-1}ty_2^{-1}ty_2t^{-1}ty_4^{-1}}_{=y_2^{-1}ty_2y_4^{-1}}\rangle \\ &= \langle t, x_2, x_3, x_4 \,|\, t^{-1}x_4tx_3^{-1}, t^{-1}x_3^{-1}x_2tx_3, t^{-1}x_2^{-1}tx_2x_4^{-1}\rangle. \\ &\quad\uparrow \\ &\quad\text{substitution } x_i = y_it^{-1},\ x_i^{-1} = ty_i^{-1}, \text{ see Lemma 53.12}\end{aligned}$$

At this point we have a presentation to which we can apply Proposition 59.32. A heroic calculation shows that $\pi(J,2)_{\text{ab}} \cong \mathbb{Z} \oplus \mathbb{Z}_5$. Thus we obtain a new proof that the figure-8 knot and the trefoil are not smoothly isotopic.

The above procedure for distinguishing knots works fairly well in practice. For example, with enough time at one's hand, or alternatively a convenient computer implementation, one can use the above methods to show that all the knots shown in the figure on page 1323 are in fact pairwise different.

Nonetheless, the above approach is not overly satisfying. It would be much better to have invariants of knots that are much quicker to calculate. We will come back to this challenge at a much later point.

The above discussion, in particular Proposition 59.32 raises the following purely algebraic question.

Question 59.33. Let π be a group with a given finite presentation and let $\phi\colon \pi \to G$ be an epimorphism onto a finite group.

(1) Is the kernel $\ker(\phi\colon \pi \to G)$ a finitely presented group?
(2) If the answer to (1) is yes, how can we determine a finite presentation for the kernel in terms of the given data?

It turns out that the answer to the first question is yes.

Proposition 59.34. If π is a finitely presented group and $\phi\colon \pi \to G$ is an epimorphism onto a finite group, then $\ker(\phi\colon \pi \to G)$ is also finitely presented.

The proof of the proposition is given in most books on combinatorial group theory, see e.g. [**LyS1977**, Chapter II.4], [**MKS1976**, Chapter 2.3] or [**Bog2008**, Chapter 2.9]. In fact the proof is algorithmic, in particular it also gives an affirmative answer to the second question. The algorithm is called the *Reidemeister-Schreier process*. The general Reidemeister-Schreier process is somewhat messy to formulate. Thus we refer to the above literature for details.

Remark. In the proof of Proposition 59.6 we showed that the group $\langle x, t \,|\, x^3 \cdot t^{-2}\rangle$ admits an epimorphism α onto the permutation group S_3. In [**Bog2008**, Example 2.9.3] the general Reidemeister-Schreier process is used to determine a presentation for the kernel of $\alpha\colon \langle x, t \,|\, x^3 \cdot t^{-2}\rangle \to S_3$.

59.8. **High-dimensional knots.** Since the study of knots in S^3 was so much fun, it would be a shame not to consider high-dimensional knots.

Definition. An n-dimensional knot in S^k is a smooth submanifold of S^k that is diffeomorphic to S^n. For $n = 1$ and $k = 3$ we say that such a knot is classical, when we allow any dimension then sometimes we say the knot is high-dimensional.

We start out with a boring example.

Example. Let $n, k \in \mathbb{N}$ with $k \geq n$. We refer to $U := \{(x, 0) \in S^{n+2} \subset \mathbb{R}^{k+1} \,|\, x \in S^n\}$ as the *trivial n-dimensional knot in S^k*.

Definition. We say an n-dimensional knot in S^k is trivial if it is smoothly isotopic to the trivial n-dimensional knot in S^k.

In Exercise **??** we showed, building on Proposition **??**, that every n-dimensional knot in a sphere of dimension $\geq 2n + 3$ is trivial. The following theorem is a refinement of this result.

Theorem 59.35. (Haefliger's (Un-)knotting Theorem)

(1) Let $n, k \in \mathbb{N}$. If $2k > 3(n + 1)$, then every n-dimensional knot in S^k is trivial.
(2) Given any $m \in \mathbb{N}$ there exists a $(4m-1)$-dimensional knot in S^{6m} that is non-trivial.

Example. It follows immediately from Haefliger's Unknotting Theorem 59.35, and an elementary calculation, that for any $n \geq 2$ every n-dimensional knot in S^{2n+1} is trivial. As we saw in Proposition 59.6, this conclusion does not hold for $n = 1$.

Proof. The first statement was proved by André Haefliger [**Hae1961a**, p. 47] in 1961. (An alternative proof is given in [**Wall2016**, p. 192].) Shortly afterwards André Haefliger [**Hae1962b**] also proved the second statement. ■

Remark. In the remainder of this section we will only consider knots of codimension two, i.e. n-dimensional knots in S^{n+2}. In principle one could also study embedded spheres of other codimensions. But first note that the Generalized Smooth Schönflies Theorem 82.5 implies that, at least for $n \neq 4$, codimension one knots in S^n are trivial. Also note that André Haefliger [**Hae1967, Hae1962a, Hae1961b, Hae1962b**] showed that in codimensions ≥ 3 there can be knots that are non-trivial. But Eric Zeeman [**Zee1963c**, p. 505] and John Stallings [**Stal1963**, Corollary 9.3] showed that knots of codimension ≥ 3 are "unknotted" in the "PL-category" and in the "topological category". Thus usually topologists tend to stick to knots of codimension two. Nonetheless, we will make use of knots of larger codimension in page **??**.

We continue with the following very unsurprising lemma.

Lemma 59.36. Let $n \in \mathbb{N}$.

(1) Let K and L be two n-dimensional knots in S^{n+2}. If K and L are smoothly isotopic, then $\pi_1(S^{n+2} \setminus K) \cong \pi_1(S^{n+2} \setminus L)$.
(2) If K is a trivial n-dimensional knot in S^{n+2}, then $\pi_1(S^{n+2} \setminus K) \cong \mathbb{Z}$.

Proof.

(1) The proof of this statement is verbatim the same as the proof of Proposition 58.4.
(2) Let K be a trivial n-dimensional knot in S^{n+2}. We see that

$$\pi_1(S^{n+2} \setminus K) \underset{\text{by (1)}}{\overset{\uparrow}{\cong}} \pi_1(S^{n+2} \setminus U) \overset{\downarrow}{\underset{\text{follows from Exercise 59.15 together with the Homotopy-}\pi_1\text{-Proposition 50.3}}{\cong}} \pi_1(S^1) \underset{\text{by Corollary 48.18}}{\overset{\uparrow}{\cong}} \mathbb{Z}.$$

■

Evidently the question now is whether there exist non-trivial high-dimensional knots. Or perhaps better, the question is whether we will manage to explicitly construct such examples. The good news is, we can indeed do so.

In the following we will present a construction, which has its origins in the work of Emil Artin [**Art1925**] and Eric Zeeman [**Zee1965**] that turns an n-dimensional knot into a family of $(n+1)$-dimensional knots. We make the following preparations:

(1) As on page 261 we make the identification $S^{n+2} = \overline{B}^{n+2}_+ \cup_{S^{n+1}} \overline{B}^{n+2}_-$.

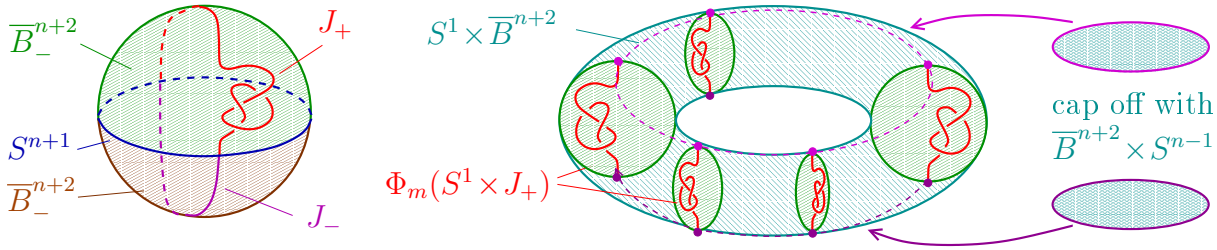
(2) By Lemma 59.1 we can make the identification $S^{n+3} = (S^1 \times \overline{B}^{n+2}) \cup_{S^1 \times S^{n+1}} (\overline{B}^2 \times S^{n+1})$.

(3) We make the identification $\mathbb{R}^{n+2} = \mathbb{C} \times \mathbb{R}^n$. In particular we view $\overline{B}^{n+2}$ as a subset of $\mathbb{C} \times \mathbb{R}^n$.

(4) Given $z \in S^1$ let

$$\begin{array}{rccc} \rho_z \colon & \overline{B}^{n+2} & \to & \overline{B}^{n+2} \\ & (w,x) & \mapsto & (z \cdot w, x) \end{array}$$

the rotation of $\overline{B}^{n+2}$ by the "angle" $z \in S^1$ around "the $0 \times \overline{B}^n$-axis".



Now let $K \subset S^{n+2}$ be a knot. It follows fairly easily from the Smooth Ball Embedding Theorem 37.8 and the fact that K is a smooth submanifold that, after possibly applying a diffeotopy of S^{n+2}, we can assume that $J_- := K \cap \overline{B}^{n+2}_- = \{(0,w) \,|\, w \in \overline{B}^n\}$ is the "trivial disk knot" in $\overline{B}^{n+2}$. We denote by $J_+ := K \cap \overline{B}^{n+2}_+$ the "other disk knot". Next, given $m \in \mathbb{Z}$ we denote by Φ_m the diffeomorphism

$$\begin{array}{rccc} \Phi_m \colon & S^1 \times \overline{B}^{n+2} & \to & S^1 \times \overline{B}^{n+2} \\ & (z,x) & \mapsto & (z, \rho_{z^m}(x)). \end{array}$$

Informally speaking Φ_m spins $\overline{B}^{n+2}$ altogether m times as we go around the S^1-direction. Note that Φ_0 is the identity and also note that each Φ_m leaves the subset $S^1 \times S^{n-1}$ invariant as a subset. Now we define the *m-twist spin* $S_m(K)$ as follows:

$$S_m(K) := \underbrace{\Phi_m(S^1 \times J_+)}_{\subset S^1 \times \overline{B}^{n+2}} \cup_{S^1 \times S^{n-1}} \underbrace{(\overline{B}^2 \times S^{n-1})}_{\subset \overline{B}^2 \times S^{n+1}} \subset \underbrace{(S^1 \times \overline{B}^{n+2}) \cup_{S^1 \times S^{n+1}} (\overline{B}^n \times S^{n+1})}_{= S^{n+3}}.$$

We leave it to the reader to verify that $S_m(K)$ is indeed an $(n+1)$-dimensional knot. In the figure below we do our best to illustrate this construction for $n = 1$. Again informally speaking, $S_m(K)$ is given by spinning the disk knot J_+ around the S^1-direction, performing m spins around J_+ as you go around S^1, and then capping off the result by $\overline{B}^2 \times S^{n-1}$.

The following proposition will show shortly, perhaps unsurprisingly, that some twist spins are non-trivial. Perhaps more surprisingly the proposition also shows that (± 1)-twist spins are always trivial.

Proposition 59.37. Let $K \subset S^{n+2}$ be an n-dimensional knot.
(1) For the 0-twist spin there exists an isomorphism $\pi_1(S^{n+3} \setminus S_0(K)) \cong \pi_1(S^{n+2} \setminus K)$.
(2) For every $\epsilon \in \{-1, 1\}$ the ϵ-twist spin knot $S_\epsilon(K)$ is trivial.

Sketch of proof.

(1) We have the following isomorphisms:

$$\begin{array}{c}
\text{by the Seifert–van Kampen Theorem 54.4, we also use that } \Phi_0(S^1 \times J_+) = S^1 \times J_+ \\
\pi_1(S^{n+3} \setminus S_0(K)) \overset{\downarrow}{\cong} \pi_1(S^1 \times (\overline{B}^{n+2} \setminus J_+)) *_{\pi_1(S^1 \times (S^{n+1} \setminus S^{n-1}))} \pi_1(\overline{B}^2 \times (S^{n+1} \setminus S^{n-1})) \\
\cong \big\downarrow \quad \text{isomorphisms given by the Fundamental Group-of-Product Proposition 48.20} \\
(\langle t \rangle \times \pi_1(\overline{B}^{n+2} \setminus J_+)) *_{\langle s \rangle \times \langle t \rangle} \langle s \rangle \\
\cong \big\uparrow \quad \text{isomorphism by the group theoretic fact that } \Gamma \xrightarrow{\cong} (\langle t \rangle \times \Gamma) *_{\langle s \rangle \times \langle t \rangle} \langle s \rangle \\
\pi_1(\overline{B}^{n+2} \setminus J_+) \\
\cong \big\downarrow \quad \text{isomorphism by Theorem 54.4} \\
\pi_1(S^{n+2} \setminus K).
\end{array}$$

By now the reader will be fully aware of the fact that it is supremely painful to completely keep track of all identifications, base points, induced maps and so on. Thus we also took some liberties to improve readability.

(2) This statement is proved implicitly in [**Zee1965**, p. 486] and explicitly in [**FO2015**, Corollary 2.1]. The reason for writing [**FO2015**] was that it felt easier to prove the statement, than to try to read the proofs written down by others. So we warmly recommend to try to prove the statement on your own. ■

Corollary 59.38. Given any $n \in \mathbb{N}$ there exists an n-dimensional knot in S^{n+2} that is non-trivial.

Proof. Let $K \subset S^3$ be the trefoil and let $n \in \mathbb{N}$. We see that

$$\pi_1(S^{n+2} \setminus (n-1)\text{-st iterated 0-twist spin of } K) \underset{\text{Proposition 59.37}}{\overset{\uparrow}{\cong}} \pi_1(S^3 \setminus K) \underset{\text{Proposition 59.5 and Proposition 59.6}}{\overset{\uparrow}{\ncong}} \mathbb{Z}.$$

It now follows from Lemma 59.36 (2) that the $(n-1)$-st iterated 0-twist spin of the trefoil is a non-trivial knot. ■

Exercises for Chapter 59.

Exercise 59.1. Let $K \subset S^3$ be a knot and let H_1 and H_2 be two hyperplanes of $\mathbb{R}^4$. For $i = 1, 2$ we denote by K_i^* the reflection of K in the hyperplane H_i. Show that K_1^* and K_2^* are smoothly isotopic.
Hint. Use the Matrix Group Path-Component Proposition 2.37 and the Smooth Path-Connectivity Proposition 19.29.

Exercise 59.2. Given $k \in \mathbb{Z}$ we consider the map

$$\begin{array}{rcl} S^1 \times S^1 & \to & S^1 \times S^1 \\ (w,z) & \mapsto & (wz^k, z). \end{array}$$

Show that $(S^1 \times \overline{B}^2) \cup_{\varphi_k} (S^1 \times \overline{B}^2)$ is homeomorphic to S^3 if and only if $k \in \{-1, 1\}$.
Hint. It might be helpful to compute the fundamental group or the first homology group of this topological space.

Exercise 59.3. We consider the two knot diagrams shown in the figure below. Use Reidemeister moves to show that the associated knots are smoothly isotopic.

Exercise 59.4. Show that every diagrammatic map has only finitely many double points.

Exercise 59.5. Let K be a knot. Use the Wirtinger Presentation Proposition 59.23 to show that the abelianization of the group $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

Exercise 59.6. Let K and L be oriented knots. We denote by L^* the mirror image of L. Show that the fundamental groups of $S^3 \setminus (K \# L)$ and $S^3 \setminus (K \# L^*)$ are isomorphic.

Exercise 59.7. We defined the sign of a crossing of a diagram of an oriented knot. How does the sign change if we reverse the orientation of the knot?

Exercise 59.8. Show that if a knot diagram has at least one crossing, then the number of crossings equals the number of strands.

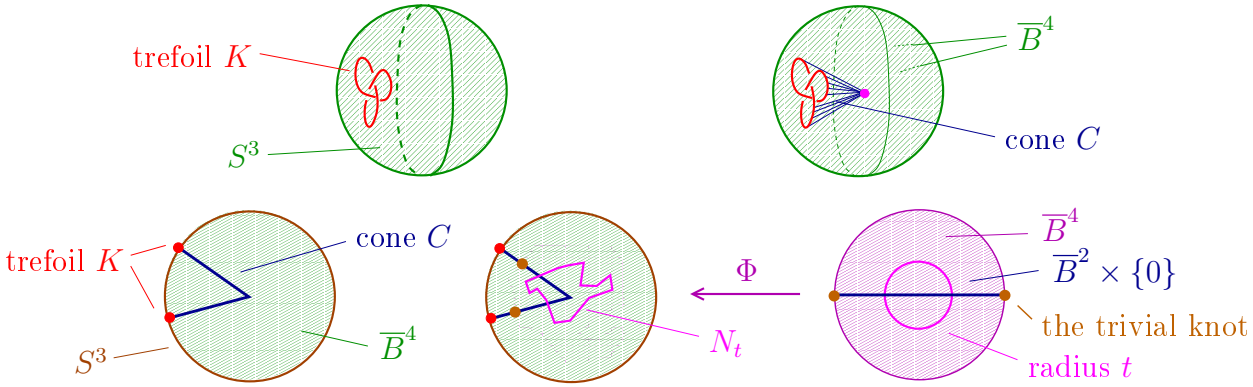
Exercise 59.9. Give a purely algebraic proof that the two groups $\langle x, y \mid x^2 = y^3 \rangle$ and $\langle a, b, c \,|\, c^{-1}bca^{-1}, b^{-1}abc^{-1} \rangle$ are isomorphic.
Remark. You could use the Tietze transformations introduced on page 1196 and you could use Lemma 53.12.

Exercise 59.10. Let $K \subset S^3$ be a knot. We consider the "cone"

$$C \;:=\; \{r \cdot P \,|\, P \in K \text{ and } r \in [0,1]\} \;\subset\; \overline{B}^4.$$

(a) Show that C is homeomorphic to the disk $\overline{B}^2$.
(b) We suppose that K is smoothly isotopic to the unknot. Show that C is a topological submanifold of the topological manifold $\overline{B}^4$.

Exercise 59.11. Let $K \subset S^3$ be the trefoil. As in Exercise 59.10 we consider the "cone"



$$C \;:=\; \{r \cdot P \,|\, P \in K \text{ and } r \in [0,1]\} \;\subset\; \overline{B}^4.$$

In Exercise 59.10 we shewed that C is homeomorphic to the disk $\overline{B}^2$. In the following we will show that C is not a submanifold of the topological manifold $\overline{B}^4$.

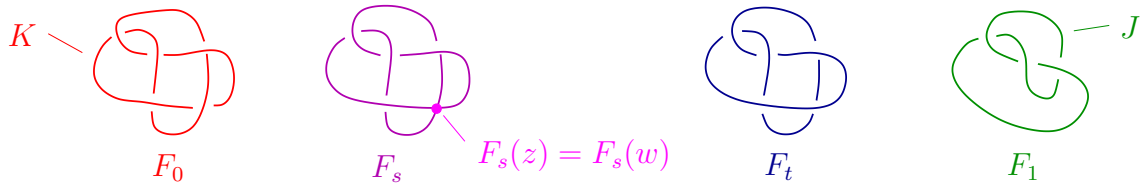
(a) Let $\alpha\colon \pi_1(S^3 \setminus K) \to \mathbb{Z}$ and $\beta\colon \mathbb{Z} \to \pi_1(S^3 \setminus K)$ be two maps. Show that the composition $\beta \circ \alpha\colon \pi_1(S^3 \setminus K) \to \pi_1(S^3 \setminus K)$ is not an isomorphism.

(b) Suppose that F is a proper 2-dimensional topological submanifold of $\overline{B}^4$. Show that given any point $P \in F \cap B^4$ there exists a map $\Phi\colon \overline{B}^4 \to \overline{B}^4$ that is an embedding such that $\Phi(0) = P$ and such that $\Phi(\overline{B}^2 \times \{0\}) = \Phi(\overline{B}^4) \cap C$.

(c) Show that C is not a *topological submanifold* of $\overline{B}^4$.
Hint. Evidently the idea is to apply (c) to the point $P = 0 \in C$. The difficulty is that the map Φ from (c) is not just a rescaling of the identity but it is potentially a completely different chart. To deal with the problem we introduce some notation.
(i) Given $I \subset [0,1]$ we write $D_I := \{v \in \overline{B}^4 \mid \|v\| \in I\}$.
(ii) Given $I \subset [0,1]$ we write $N_I := \Phi(D_I)$.
(iii) Given $t \in (0,1]$ we write $D_t := D_{\{t\}}$ and $N_t := N_{\{t\}}$.
Show that the following statements hold:
(1) Given any $t \in (0,1]$ there exists an $s \in (0,1)$ with $D_{[0,s]} \subset N_{[0,t)}$.
(2) Given any $s \in (0,1]$ there exists a $t \in (0,1)$ with $N_{[0,t]} \subset D_{[0,s)}$.
(3) Given any choice of $r < s$ in $(0,1]$ the two inclusion maps $D_r \backslash C \to D_{[r,s]} \backslash C$ and $D_s \backslash C \to D_{[r,s]} \backslash C$ are homotopy equivalences, in particular they induce isomorphism of fundamental groups. Each of the fundamental groups is isomorphic to $\pi_1(S^3 \setminus K)$.
(4) Given any choice of $r < s$ in $(0,1]$ the two inclusion maps $N_r \backslash C \to N_{[r,s]} \backslash C$ and $N_s \backslash C \to N_{[r,s]} \backslash C$ are homotopy equivalences, in particular they induce isomorphism of fundamental groups. Each of the fundamental groups is isomorphic to $\mathbb{Z}$.
(5) Use the above discussion together with (b) to show that such Φ cannot exist.

Exercise 59.12. Let K be the trefoil. Compute the abelianization of the group $\pi(K, 3)$.

Exercise 59.13. Let π be a group. We say that a subset $S \subset \pi$ *normally generates* π if $\langle\langle S \rangle\rangle = \pi$. We define the *weight of* π as



$$w(\pi) := \min\{\#S \mid S \text{ is a subset of } \pi \text{ that normally generates } \pi\} \in \mathbb{N}_0 \cup \{\infty\}.$$

(a) Determine the weight of $\mathbb{Z}^m$.
(b) Determine the weight of the free group on m generators.
(c) Let $K \subset S^3$ be a knot. Show that $w(\pi_1(S^3 \setminus K)) = 1$.

Exercise 59.14. We say two knots K and J in $\mathbb{R}^3$ are related by a *crossing change* if there exists a smooth map $F\colon S^1 \times [0,1] \to \mathbb{R}^3$ and some $s \in (0,1)$ with the following properties:
(1) We have $F_0(S^1) = K$ and $F_1(S^1) = J$.

(2) For every $t \neq s$ the map $F_t\colon S^1 \to S^3$ is an embedding.
(3) The map $F_s\colon S^1 \to S^3$ is an immersion and there exist $w, z \in S^1$ with the following properties:
   (i) the restriction of F_s to $S^1 \setminus \{w, z\}$ is an injection,
   (ii) $F_s(w) = F_s(z)$ and the vectors $F_s'(w)$ and $F_s'(z)$ are linearly independent.

In the figure below we illustrate the definition of a crossing change.

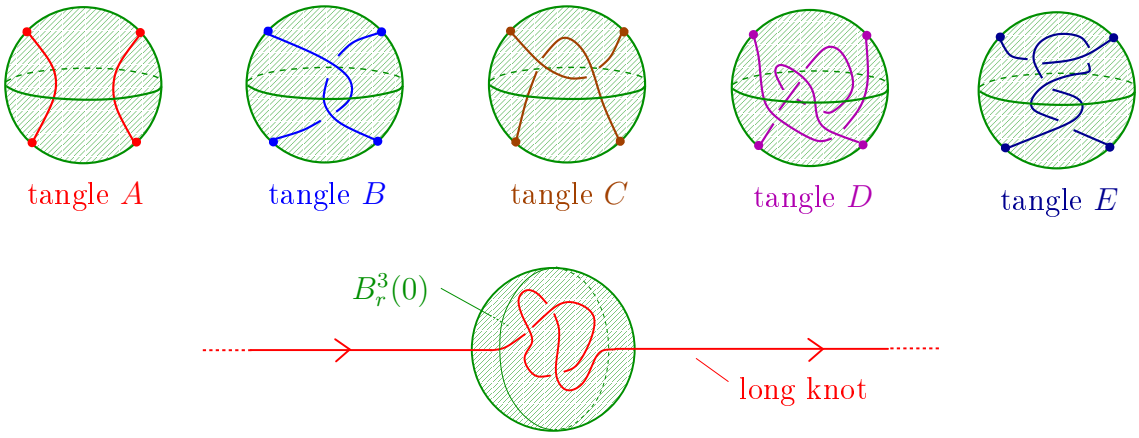
Given two knots K and J the minimal number of crossing changes needed to turn K into J is called the *Gordian distance between K and J*. The Gordian distance of a knot K to the trivial knot is called the *unknotting number of K*. Given explicit knots these numbers are notoriously difficult to calculate.

(a) Show that any two knots in $\mathbb{R}^3$ are related by a sequence of finitely many crossing changes. In other words, show that the Gordian distance between two knots is finite. *Hint.* You could use the fact that every knot admits a knot diagram.
(b) What are the best lower and upper bounds you can find on the Gordian distance between the trefoil and the figure-8 knot?

Remark. For readers who prefer completely formal proofs it can be a fun challenge to tweak the argument of the proof of Proposition **??** to obtain a proof of (a).

Exercise 59.15. Let $n \in \mathbb{N}$ and let $k \in \{1, \dots, n-1\}$. We consider the submanifold $K := \{(x, 0) \in \mathbb{R}^{n+1} \mid x \in S^k\}$. Show that $S^n \setminus K$ is homotopy equivalent to S^{n-k-1}.

Exercise 59.16. Let $K \subset S^3$ be an oriented knot and let $m \in \mathbb{Z}$. As on page 1339 we consider the m-twist spin $S_m(K) \subset S^4$. We view S^3 as a subset of S^4 via the embedding $z \mapsto (z, 0)$. The intersection $S_m(K) \cap S^3$ is a knot. What is the smooth isotopy type of this knot? A possible answer is that this knot is a connected sum of K with some suitable other knot.



Exercise 59.17. A *tangle* is a proper 1-dimensional submanifold of $\overline{B}^3$. We consider the five tangles shown in the figure below. Note that the boundary of each of the four tangles is the same.

(a) For which pairs S, T of the five tangles does there exist an orientation-preserving diffeomorphism $\varphi\colon \overline{B}^3 \to \overline{B}^3$ with $\varphi(S) = T$?
(b) For which pairs S, T of the five tangles does there exist an orientation-preserving diffeomorphism $\varphi\colon \overline{B}^3 \to \overline{B}^3$ with $\varphi(S) = T$ and with $\varphi|_{S^2} = \mathrm{id}_{S^2}$.

Exercise 59.18. We start out with a few definitions.

(1) A *long knot* is a submanifold K of $\mathbb{R}^3$ that is diffeomorphic to $\mathbb{R}$ and which has the property that there exists an $r > 0$ such that

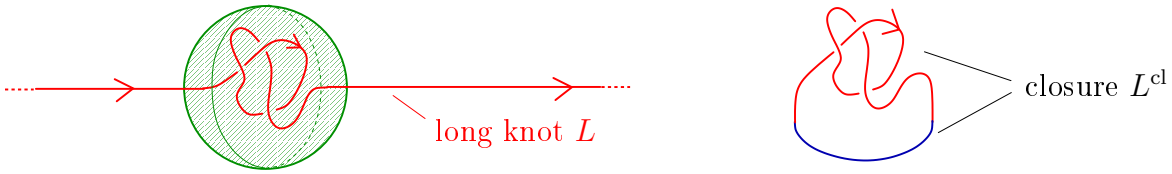
$$K \cap (\mathbb{R}^3 \setminus B_r^3(0)) \;=\; (\mathbb{R} \times \{(0,0)\}) \cap (\mathbb{R}^3 \setminus B_r^3(0)).$$

A long knot comes with a natural orientation given by "going from $-\infty$ to ∞".

(2) We say two long knots K and J are *equivalent* if there exists a *proper*[708] smooth isotopy $F\colon \mathbb{R}\times[0,1]\to\mathbb{R}^3$, in the sense of the definition on page 812, such that $F_0(\mathbb{R})=K$, $F_1(\mathbb{R})=J$ and such that each $F_t(\mathbb{R})$ is a long knot.

(3) Let L be a long knot. We pick an $r>0$ such that

$$L\cap B^3_r(0) \;\subset\; \mathbb{R}\times\{(0,0)\}.$$



We denote by

$$\begin{array}{rcl}\Phi\colon \overline{B}^3_{2r}(0) & \to & S^3\\ x & \mapsto & \left(\frac{x}{2r}, \sqrt{1-|\frac{x}{2r}|^2}\right)\end{array}$$

the obvious smooth embedding whose image is precisely the upper hemisphere. We refer to

$$L^{\mathrm{cl}} \;:=\; \Phi\big(L\cap\overline{B}^3_{2r}(0)\big)\cup\big\{\big(x,0,0,\sqrt{1-x^2}\,\big)\,|\,x\in[-1,1]\big\}$$

as the *closure* L^{cl} *of the long knot* L. Note that the closure inherits an orientation from L.

Now we turn to the actual exercises:

(a) There is a pretty obvious definition of a composition $L\#L'$ of long knots L and L'. Turn this idea into a proper definition. Are $L\#L'$ and $L\#L'$ equivalent?

(b) Show that the fundamental groups of $\mathbb{R}^3\setminus L$ and $S^3\setminus L^{\mathrm{cl}}$ are isomorphic.

(c) Show that the closure L^{cl} is well-defined up to smooth isotopy and show that the map

$$\begin{array}{rcl}\{\text{long knots up to equivalence}\} & \to & \{\text{oriented knots up to smooth isotopy}\}\\ [L] & \mapsto & [L^{\mathrm{cl}}]\end{array}$$

is a bijection.

[708] The discussion in Exercise 36.9 shows that we cannot drop the requirement that the smooth isotopy is proper.

Exercise 59.19. We consider the epimorphism

$$\phi\colon \mathbb{Z}_2 * \mathbb{Z}_2 = \langle a, b \,|\, a^2, b^2 \rangle \;\to\; \mathbb{Z}_2$$

that is given by $\phi(a) = \phi(b)$. Show that $\ker(\phi)$ is isomorphic to $\mathbb{Z}$.
Hint. Use the Reidemeister-Schreier Process 59.32.

60. Decision problems

In the last chapters we had developed several techniques for determining the fundamental groups of topological spaces. In particular we managed to find finite presentations for the fundamental groups of large classes of topological spaces, e.g. topological graphs, surfaces, knot complements and mapping tori. In fact we now have enough tools to determine, with enough effort and perseverance, a presentation for the fundamental groups of most "nice" spaces. Furthermore we will see later in Propositions 96.6 and 104.14 on that the fundamental group of every compact topological manifold admits a *finite* presentation.
The question that now arises is, what information can we extract from a finite presentation of a group? Here are a couple of natural questions.

Question 60.1.

(1) Does there exist an algorithm that can decide whether or not a given finite presentation $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ represents the trivial group?
(2) Does there exist an algorithm that can decide whether or not two given finite presentations $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ and $\Gamma = \langle h_1, \dots, h_m \mid s_1, \dots, s_n \rangle$ represent isomorphic groups?[709]
(3) Does there exist an algorithm that can determine, given
   (a) a finite presentation $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ and
   (b) a word w in $g_1, \dots, g_k$, i.e. an element $w \in \langle g_1, \dots, g_k \rangle$,
   whether or not w represents the trivial element in the group π?[710]
(4) Does there exist an algorithm that can determine, given
   (a) a finite presentation $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ and
   (b) and two words v and w in $g_1, \dots, g_k$,
   whether or not v and w represent conjugate elements in the group π?[711]

Remark.

(1) This question was first posed by Max Dehn [**Deh1911**] in 1911. In fact shortly afterwards, in 1912 Max Dehn [**Deh1912**] gave positive answers to the word problem and the conjugacy problem for the fundamental groups of compact 2-dimensional smooth manifolds.
(2) The above question is formulated in a slightly informal way. After all, what is an "algorithm" supposed to be? The questions are made more precise in [**CZ1993**, Chapter 7], [**Stil1982**] and [**MillC1992**].

On page 1196 we introduced the Tietze transformations on presentations. We pointed out that two finite presentations for a given group are in fact related by a finite sequence of Tietze transformations. In particular, if $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ is a presentation for the trivial group, then we can turn the presentation after finitely many Tietze transformations into the trivial presentation $\langle | \rangle$. The problem is that we do not know how many Tietze transformations are required to turn a presentation of a trivial group into a trivial presentation. In particular at times it can be very hard to find the correct Tietze transformations.

[709] The question whether such an algorithm exists is often called the *isomorphism problem*.
[710] The question whether such an algorithm exists is often called the *word problem*.
[711] The question whether such an algorithm exists is often called the *conjugacy problem*.

Example. We consider the presentation

$$\pi \;=\; \langle a, b, c \mid a^3, b^3, c^4, ac = ca^{-1}, aba^{-1} = bcb^{-1}\rangle.$$

This is a presentation of the trivial group as can be seen as follows:[712]

(1) from $aba^{-1} \sim bcb^{-1}$ we get $(aba^{-1})^3 \sim (bcb^{-1})^3$,
(2) since $a^{-1}a \sim 1$ and $b^{-1}b \sim 1$ it follows that $(aba^{-1})^3 \sim ab^3a^{-1}$ and $(bcb^{-1})^3 \sim bc^3b^{-1}$,
(3) we have $b^3 \sim 1$, hence $ab^3a^{-1} \sim 1$, therefore we get from (1) and (2) that $bc^3b^{-1} \sim 1$ hence $c^3 \sim 1$,
(4) we have $c^3 \sim 1$ but we also have the relation $c^4 \sim 1$, so $c \sim 1$,
(5) since $aba^{-1} \sim bcb^{-1}$ it follows that $aba^{-1} \sim 1$ and so $b \sim 1$,
(6) from $ac \sim ca^{-1}$ and $c \sim 1$ it follows that $a \sim a^{-1}$, hence $a^2 \sim 1$,
(7) together with $a^3 \sim 1$ we obtain $a \sim 1$.
(8) we now showed that a, b, c are all equivalent to 1, thus we see that the group defined by the presentation is the trivial group.

This example shows that if a presentation corresponds to the trivial group, then it can be surprisingly complicated to verify this statement.

Now suppose we are given a finite presentation and we have to decide whether or not it is a presentation of the trivial group. We can modify the presentation using Tietze transformations. If at some point we end up with the trivial presentation we know that the given presentation corresponds to the trivial group. But what happens if after many attempts at modifying the presentation using Tietze transformations we still do not have the trivial presentation. Does that mean that the presentation corresponds to a non-trivial group? Or does it just mean that we did not try long enough?
So the real question is, does there exist an algorithm, that given a presentation which defines a non-trivial group, actually verifies that the group is non-trivial?
Unfortunately the answer is quite sobering.

Theorem 60.2. The answer to all four questions raised in Question 60.1 is no.

Remark. Here "no" means that one can show that no such algorithm exists. This is a much stronger statement than saying that we do not know of an example of such an algorithm.

Proof.

(1) Adyan [**Ady1955**] and Michael Rabin [**Rabi1958**] showed in 1955 that the answer to the first question is no. Alternatively see [**MillC1992**, Theorem 3.3] for a proof.
(2) An algorithm that performs (2) would also give an algorithm for determining whether or not a given presentation is isomorphic to the trivial group with the empty presentation $\langle|\rangle$. But since the answer to (1) is no, it follows that the answer to (2) is also no. Historically, it was first proved by Sergey Novikov [**Nov1965**] and William Boone [**Boo1958**] that (2) has a negative answer before a negative answer to (1) was given.
(3) If there did exist an algorithm that dealt with the third problem, then we could apply it in particular to the generators. Since a presentation presents the trivial group if and only if all generators are trivial, it follows that an algorithm for (3) would also

[712] For elements g, h of $\langle a, b, c\rangle$ we write $g \sim h$ if they represent the same element in π.

give an algorithm for (1). Since the latter cannot exist, the former cannot exist either.

(4) An element in a group is trivial if and only if it is conjugate to the trivial element. Hence the fact that (3) has a negative answer leads to a negative answer to (4). ■

Remark.

(1) There are many other non-existence results in the vein of Theorem 60.2. For example, [**MillC1992**, Corollary 3.4], see also Exercise 60.2 says the following:
   (a) it is undecidable whether a finitely presented group is free,
   (b) it is undecidable whether a finitely presented group is abelian,
   (c) it is undecidable whether a finitely presented group is nilpotent,
   (d) it is undecidable whether a finitely presented group is solvable,
   (e) it is undecidable whether a finitely presented group is simple,
   (f) it is undecidable whether a finitely presented group is torsion-free.

(2) The statement of Theorem 60.2 that the answer to all four questions of Question 60.1 is no, is of course somewhat disappointing. But this raises the question whether there are interesting classes of groups for which the answer is actually yes. For example Mikhail Gromov [**Grom1987**][713] introduced the notion of a "word hyperbolic group" for which the answer to all four questions turns out to be yes. Examples of word hyperbolic groups are given by
   (a) finite groups,
   (b) free groups, fundamental groups of surfaces of genus ≥ 2,
   (c) fundamental groups of hyperbolic smooth manifolds of any dimension,
   (d) fundamental groups of "Riemannian manifolds with negative sectional curvature".

   In fact in a precise sense a "random" finitely presented group is word hyperbolic, see e.g. [**Ol2005**] for more details.

   The topic of word hyperbolic groups is a very important topic of mathematics in its own right. See e.g. [**Löh2015**] for an introduction to word hyperbolic groups.

Of course our main goal is not to classify groups, but our goal is to understand "nice" topological spaces. For example ideally we would like to classify compact topological and smooth manifolds. The following theorem gives us some hope that this task is not completely hopeless.

Theorem 60.3. Let $n \in \mathbb{N}_0$.

(1) There exist only countably many homeomorphism classes of compact n-dimensional topological manifolds.

(2) There exist only countably many diffeomorphism classes of compact n-dimensional smooth manifolds.

Proof. The first statement is proved in [**CK1970**]. The second statement follows from [**Pets1984**, p. 77] and the fact that every smooth manifold admits a Riemannian structure, see e.g. [**Wall2016**, Theorem 1.3.1]. For $n \geq 6$ the second statement can also be

[713] Mikhail Gromov (1943-) is a French-Russian mathematician famous for his many contributions to geometry and group theory. He was the first person to view groups as "geometric objects", giving rise to the subject of "geometric group theory".

deduced from the fact that every compact n-dimensional smooth manifold admits a finite simplicial structure, see the Smooth Manifold-Simplicial Structure Theorem 96.2, the fact that there are only countably many isomorphism classes of finite simplicial complexes, see Exercise 93.4, and the (very difficult) Theorem **??** which says that for $n \geq 6$ every compact topological manifold admits at most finitely many smooth structures. ■

Given $n \in \mathbb{N}$ we would like to classify closed orientable connected n-dimensional smooth manifolds up to diffeomorphism. For $n = 1$ we did so in the Smooth 1-Dimensional Manifold Classification Theorem 22.7 and for $n = 2$ we saw the classification in the Surface Classification Theorem 55.4. In particular we saw that in these dimensions only "few groups" appear as fundamental groups.

We also proved the following result which shows that in dimension ≥ 4 the situation is dramatically different.

Proposition 54.12. Given any finitely presented group π and any $n \geq 4$ there exists a closed orientable connected n-dimensional smooth manifold with fundamental group π.

Theorem 60.2 and the Fundamental Group-Manifold Realization Proposition 54.12 are at the heart of the proof of the following theorem.

Theorem 60.4. Let $n \geq 4$.

(1) Then there is no algorithm that can decide whether or not two closed orientable n-dimensional smooth manifolds are homeomorphic.
(2) Then there is no algorithm that can decide whether or not two closed orientable n-dimensional smooth manifolds are diffeomorphic.

Proof. The first statement was first proved by Markov [**Mark1958**]. We refer to [**BHP1968**, Theorem 1] and [**Hak1973**] for a detailed discussion of the proofs of both statements. ■

This leaves us with the case of 3-dimensional smooth manifolds. It turns out that in this dimension there does in fact exist such an algorithm.

Theorem 60.5. There exists an algorithm that can decide whether or not two closed orientable connected 3-manifolds are diffeomorphic.

In this case the algorithm is considerably more complicated than in the 1-dimensional and the 2-dimensional case. The proof that such an algorithm exists is due to the work of many mathematicians, first and foremost William Thurston [**Thu1982**] and Grigori Perelman. The proof of the theorem was completed about 2003. It is impossible to mention here all the work that goes into proving Theorem 60.5. We refer to the survey paper [**AFW2015**, Theorem 4.27] for details and precise references.

Exercises for Chapter 60.

Exercise 60.1.

(a) Show that every finite group is isomorphic to some permutation group S_n.
(b) Let $\pi = \langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle$ be a finitely presented group. Suppose that we know that π is finite. Show that there exists an algorithm which determines an injective homomorphism $\varphi\colon \pi \to S_n$ for some $n \in \mathbb{N}$.

(c) Let $\pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle$ and $\Gamma = \langle h_1, \ldots, h_m \mid s_1, \ldots, s_n \rangle$ be two finitely presented groups. Suppose we know that π and Γ are finite. Show that there exists an algorithm that can determine whether or not π and Γ are isomorphic.

Exercise 60.2.

(a) Show that it is undecidable whether a finitely presented group is free.
(b) Show that it is undecidable whether a finitely presented group is abelian.
(c) Show that it is undecidable whether a finitely presented group is nilpotent.
(d) Show that it is undecidable whether a finitely presented group is solvable.

Somewhat more precisely, for each group property show that there is no algorithm that can decide whether or not a given finite presentation $\pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle$ represents a group that has said property.

Exercise 60.3. A group π is called *residually finite* if given any non-trivial element $g \in \pi$ there exists a homomorphism $\alpha \colon \pi \to G$ to a finite group G such that $\alpha(g)$ is non-trivial. Show that the word problem is solvable in a finitely generated group that is residually finite.
Remark. A solution to this exercise can be found in [**MillC1992**, Theorem 5.2].

Part VI

The universal covering

61. The existence of universal coverings

After spending a lot of time on determining the fundamental groups of topological spaces we now want to return to the study of covering maps. One key goal of this section is to address the following question.

Question 61.1. Does every path-connected topological space B admit a path-connected covering $p\colon X \to B$ such that X is simply connected?

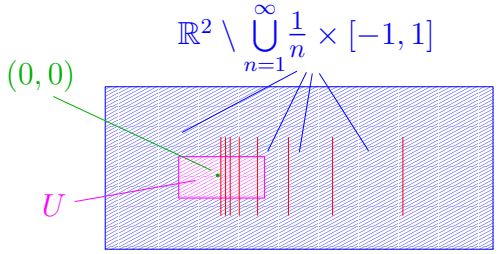
We know of course that the answer is yes for the torus, the Klein bottle and the Möbius band. But does such a covering exist for the surface of genus 2? Or does it exist for the complement $S^3 \setminus K$ of a knot $K \subset S^3$? How about the wedge $S^1 \vee S^1$ of two circles?

61.1. Local properties of topological spaces.

Before we can address Question 61.1 we need to recall the definition of a local property of topological spaces that we already gave in Section 2.8.

Definition. Let P be a property of topological spaces. We say a topological space X is locally P if given any $Q \in X$ and any neighborhood U of Q there exists an open neighborhood V of Q that is contained in U that has the property P.

Examples.



(1) By the Homotopy-π_1-Proposition 50.3 we know that every contractible topological space is simply connected. Thus every locally contractible topological space is also locally simply connected. Furthermore every simply connected space is by definition path-connected, thus every locally simply connected space is also locally path-connected.

(2) On page 176 we saw that every open subset of $\mathbb{R}^n$ is locally simply connected.

(3) By the Topological Manifolds-Local Properties Lemma 18.8 (1) every topological manifold is locally homeomorphic to some non-empty convex subset of $\mathbb{R}^n$. Since non-empty convex subsets are contractible we see that every topological manifold is locally contractible.

(4) In Exercise 61.1 we will show that every topological graph is locally contractible and we will show that the wedge of locally contractible topological spaces is again locally contractible.

(5) We consider
$$X := \mathbb{R}^2 \setminus \bigcup_{n=1}^{\infty} \left\{\tfrac{1}{n}\right\} \times [-1,1],$$
with the usual subspace topology coming from $\mathbb{R}^2$. Then X is path-connected but not locally path-connected. Indeed, we consider the point $(0,0) \in X$ and the neighborhood $U = (-\frac{1}{2},\frac{1}{2}) \times (-\frac{1}{2},\frac{1}{2}) \cap X$. It is straightforward to show that there does not exist a path-connected neighborhood V of $(0,0)$ which is contained in U.

(6) We consider

$$X \;:=\; \mathbb{R}^2 \;\setminus\; \bigcup_{n=1}^{\infty} \big(\tfrac{1}{n}, 0\big),$$

with the subspace topology coming from $\mathbb{R}^2$. Then X is path-connected, locally path-connected but it is not locally simply connected. Indeed the origin admits no neighborhood of the desired form, since any neighborhood of the origin contains "infinitely many holes". We made this statement precise in Exercise 52.1.

61.2. **Lifting maps to coverings.** Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let $f\colon (Z, z_0) \to (B, b_0)$ be a map. Recall that on page 1080 we said that f *lifts*, if there exists a *lift* $\widetilde{f}\colon (Z, z_0) \to (X, x_0)$, i.e. a map $\widetilde{f}\colon Z \to X$ with $\widetilde{f}(z_0) = x_0$ and which makes the following diagram commute

$$\begin{array}{ccc} & & (X, x_0) \\ & \overset{\widetilde{f}}{\nearrow} & \big\downarrow p \\ (Z, z_0) & \xrightarrow[f]{} & (B, b_0). \end{array}$$

For example, if $f\colon ([0,1], 0) \to (B, b_0)$ is a map from the interval $[0,1]$ to B, i.e. if f is a path with starting point b_0, then we saw in Proposition 48.11 that there exists a unique lift of f to a map $\widetilde{f}\colon ([0,1], 0) \to (X, x_0)$.

Example. Consider the following maps:

$$\begin{array}{ccc} & & (S^1, 1) \\ & \overset{???\ \text{lift}\ \widetilde{f}\ ???}{\nearrow} & \big\downarrow p \;z\mapsto z^3 \\ (S^1, 1) & \xrightarrow[f]{z\mapsto z^2} & (S^1, 1). \end{array}$$

Here the map p is a 3-fold covering. Does the map f lift to a map $\widetilde{f}$?

To answer the question we need to study lifts of maps more carefully. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces and let $f\colon (Z, z_0) \to (B, b_0)$ be a map. Suppose that there exists a lift $\widetilde{f}\colon (Z, z_0) \to (X, x_0)$. We then obtain the commutative diagram

$$\begin{array}{ccc} & & (X, x_0) \\ & \overset{\widetilde{f}}{\nearrow} & \big\downarrow p \\ (Z, z_0) & \xrightarrow[f]{} & (B, b_0) \end{array}$$

from the functoriality of the fundamental group it follows that $f_* = \big(p \circ \widetilde{f}\big)_* = p_* \circ \widetilde{f}_*$, i.e. we get the commutative diagram

$$\begin{array}{ccc} & & \pi_1(X, x_0) \\ & \overset{\widetilde{f}_*}{\nearrow} & \big\downarrow p_* \\ \pi_1(Z, z_0) & \xrightarrow[f_*]{} & \pi_1(B, b_0). \end{array}$$

Thus it follows that if f lifts, then

$$\operatorname{im}(f_*) \;=\; \operatorname{im}\big(\big(p \circ \widetilde{f}\big)_*\big) \;=\; \operatorname{im}\big(p_* \circ \widetilde{f}_*\big) \;\subset\; \operatorname{im}(p_*).$$

So summarizing, if there exists a lift of f, then

$$\operatorname{im}(f_*\colon \pi_1(Z, z_0) \to \pi_1(B, b_0)) \;\subset\; \operatorname{im}(p_*\colon \pi_1(X, x_0) \to \pi_1(B, b_0)).$$

Example. In the above example we have $\pi_1(S^1, 1) = \mathbb{Z}$ and $\operatorname{im}(f_*) = 2\mathbb{Z}$ whereas we have $\operatorname{im}(p_*) = 3\mathbb{Z}$. So we see that f does not lift.

The following proposition says, that the above conclusion has a converse, for "reasonably" topological spaces. More precisely, we have the following proposition which, under a modest technical hypothesis, gives a complete criterion for when a map lifts.

Proposition 61.2. (Map Lifting Criterion) Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected topological space and let $f\colon (Z, z_0) \to (B, b_0)$ be a map.

(1) If Z is locally path-connected, then we have the following equivalence of statements:

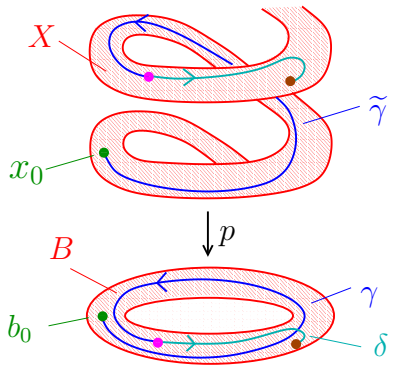
$$\begin{array}{ccc} & & (X, x_0) \\ & \overset{\text{there exists a lift } \widetilde{f}}{\nearrow} & \downarrow p \\ (Z, z_0) & \xrightarrow[f]{} & (B, b_0) \end{array} \qquad \Longleftrightarrow \qquad \operatorname{im}(f_*) \subset \operatorname{im}(p_*).$$

(2) There exist at most one such lift, in other words, any two such lifts agree.[714]

Examples. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces.

(1) The condition on the fundamental groups in the Map Lifting Criterion 61.2 is automatically satisfied if Z is simply connected.
(2) Now let $f\colon (S^n, s_0) \to (B, b_0)$ be a map. The topological manifold S^n is path-connected and locally path-connected. By the Sphere-π_1-Proposition 47.13 the sphere S^n is simply connected if $n \geq 2$. Thus it follows from (1) that there exists a uniquely determined lift $\widetilde{f}\colon (S^n, s_0) \to (X, x_0)$ of the map $f\colon (S^n, s_0) \to (B, b_0)$.

Remark. In Exercise 61.4 we will see that we cannot drop the hypothesis that Z is locally path-connected.



In the proof of the Map Lifting Criterion 61.2 we will need the following lemma.

Lemma 61.3. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed spaces, let γ be a path in B with starting point b_0 and let δ be another path in B with $\delta(0) = \gamma(1)$. We denote by $\widetilde{\gamma}$ the lift of γ with starting point x_0. Then

$$\begin{array}{c}\text{endpoint of the lift of } \gamma * \delta \\ \text{to the starting point } x_0\end{array} = \begin{array}{c}\text{endpoint of the lift of } \delta \\ \text{to the starting point } \widetilde{\gamma}(1).\end{array}$$

Proof. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed spaces, let γ be a path in B with starting point b_0 and let δ be another path in B with $\delta(0) = \gamma(1)$. We denote by $\widetilde{\gamma}$ the lift of γ with starting point x_0 and we denote by $\widetilde{\delta}$ the lift of δ to the starting point $\widetilde{\gamma}(1)$. Finally we denote by $\widetilde{\gamma * \delta}$ the lift of $\gamma * \delta$ to the starting point x_0. For $t \in [0, 1]$ we write $\beta(t) = (\gamma * \delta)(\frac{1}{2}(t+1))$ and $\widetilde{\beta}(t) = (\widetilde{\gamma * \delta})(\frac{1}{2}(t+1))$. Note that by definition we have $\beta(t) = \delta(t)$ for $t \in [0, 1]$ and that $\widetilde{\beta}$ and $\widetilde{\delta}$ are both lifts of $\beta = \delta$ to the starting point

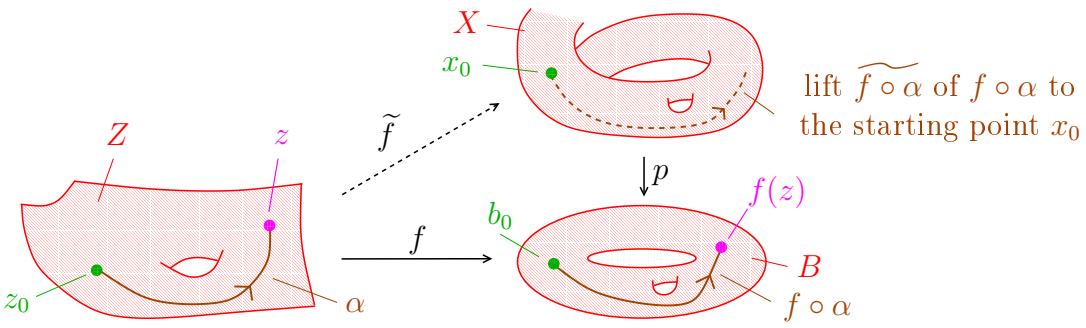
[714] Note that for (2) we do not need the annoying hypothesis that Z is locally path-connected.

$\beta(0) = \gamma(1) = \delta(0)$. Thus it follows that

$$\text{endpoint of } \widetilde{\gamma * \delta} \;=\; \widetilde{(\gamma * \delta)}(1) \;=\; \widetilde{\beta}(1) \;\underset{\uparrow}{=}\; \widetilde{\delta}(1) \;=\; \text{endpoint of } \widetilde{\delta}.$$

by Proposition 48.11 ■

Now we can give the proof of the Map Lifting Criterion 61.2. To make the proof slightly more readable we prove the two statements (1) and (2) separately.



Proof of the Map Lifting Criterion 61.2 (1). Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected and locally path-connected topological space and let $f\colon (Z, z_0) \to (B, b_0)$ be a map.

By the discussion on page 1353 we only have to prove the "$\Longleftarrow$"-direction of the proposition. So suppose that we have

$$\operatorname{im}(f_*\colon \pi_1(Z, z_0) \to \pi_1(B, b_0)) \;\subset\; \operatorname{im}(p_*\colon \pi_1(X, x_0) \to \pi_1(B, b_0)).$$

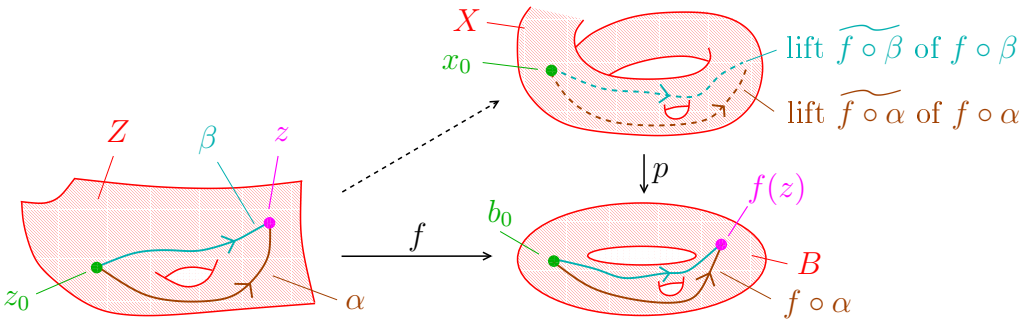
We have to construct a lift $\widetilde{f}\colon (Z, z_0) \to (X, x_0)$. We will do so as follows. Let $z \in Z$ be a point. Since Z is path-connected we can find a path $\alpha\colon [0,1] \to Z$ with $\alpha(0) = z_0$ and $\alpha(1) = z$. According to Proposition 48.11 we can lift the path $f \circ \alpha\colon [0,1] \to B$ to a path $\widetilde{(f \circ \alpha)}\colon [0,1] \to X$ with starting point x_0. We define

$$\widetilde{f}(z) \;:=\; \widetilde{(f \circ \alpha)}(1).$$

We have to verify the following statements:

(1) the map $\widetilde{f}\colon Z \to X$ is well-defined,

(2) the map $\widetilde{f}$ is continuous,



(3) the map $\widetilde{f}$ is a lift.
(4) and the map $\widetilde{f}$ is the unique lift.

We will do so in the following:

(1) We have to show that for $z \in Z$ the point $\widetilde{f}(z) \in X$ is well-defined, i.e. independent of the choice of the path α. Thus let $\beta\colon [0,1] \to Z$ be another path with $\beta(0) = z_0$ and $\beta(1) = z$. (This situation is illustrated in the figure below.) It follows that

$$\begin{aligned}
\widetilde{(f \circ \alpha)}(t=1) &= (\text{lift of } f \circ \alpha \text{ to the starting point } x_0)(t=1) \\
&= (\text{lift of } (f \circ \alpha) * \overline{(f \circ \beta)} * (f \circ \beta) \text{ to the starting point } x_0)(t=1) \\
&\quad \uparrow \\
&\quad \text{by Corollary 48.13 since } f \circ \alpha \text{ and } (f \circ \alpha) * \overline{(f \circ \beta)} * (f \circ \beta) \text{ are path-homotopic} \\
&= (\text{lift of } (f \circ (\underbrace{\alpha * \overline{\beta}}_{=:\gamma,\ \text{a loop in } (Z, z_0)})) * (f \circ \beta) \text{ to the starting point } x_0)(t=1) \\
&= (\text{lift of } f \circ \beta \text{ to the starting point } (\widetilde{f \circ \gamma})(1))(t=1) \\
&\quad \uparrow \\
&\quad \text{Lemma 61.3, where } \widetilde{f \circ \gamma} \text{ denotes the lift of } f \circ \gamma \text{ to the starting point } x_0 \\
&= (\text{lift of } f \circ \beta \text{ to starting point } x_0)(t=1) \;=\; \widetilde{(f \circ \beta)}(t=1). \\
&\quad \uparrow \\
&\quad \text{by our hypothesis we have } [f \circ \gamma] = f_*([\gamma]) \in \operatorname{im}(f_*) \subset p_*(\pi_1(X, x_0)), \\
&\quad \text{hence } \widetilde{f \circ \gamma} \text{ is a loop in } x_0 \text{ by Lemma 48.15}^{715}
\end{aligned}$$

Thus we have shown that the map $\widetilde{f}$ is well-defined.

(2) Now we want to show that $\widetilde{f}$ is continuous. So let $z \in Z$. We pick a path α from z_0 to z. Since p is a covering there exists an open neighborhood V of $\widetilde{f}(z)$ such that the restriction of p to V is an embedding. We denote by $q\colon p(V) \to V$ the inverse map. Since Z is locally path-connected there exists an open neighborhood U of z that is contained in $f^{-1}(p(V))$ and that is path-connected. Since f and q are continuous it suffices to prove the following claim.

Claim. On the open neighborhood U of z the map $\widetilde{f}$ agrees with $q \circ f$.

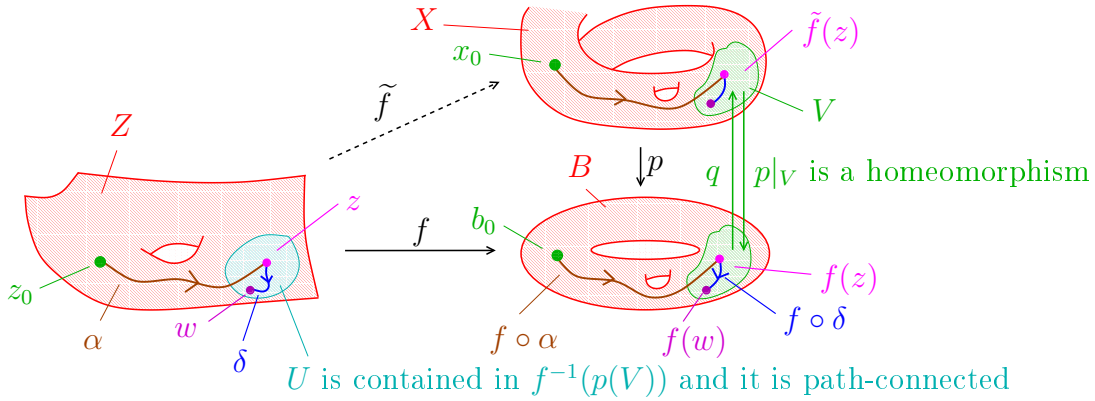
---

[715] Lemma 48.15 (1) says the following: if δ is a loop in (B, b_0) and if $\widetilde{\delta}$ denotes the lift of δ to the starting point x_0, then the following holds:

$$\widetilde{\delta} \text{ is a loop in } (X, x_0) \iff [\delta] \text{ lies in } p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0).$$

We apply the lemma to $\delta = f \circ \gamma$.

Proof. So let $w \in U$. Since U is path-connected there exists a path δ from z to w that lies in U. Then



$$\begin{aligned}\widetilde{f}(w) &= \text{endpoint of the lift of } f\circ(\alpha*\delta) = (f\circ\alpha)*(f\circ\delta) \text{ to the starting point } x_0\\ &= \text{endpoint of the lift of } f\circ\delta \text{ to the starting point } \widetilde{f}(z)\\ &\quad\uparrow \text{ by Lemma 61.3 and the definition of } \widetilde{f}(z) \text{ as the endpoint of } \widetilde{f\circ\alpha}\\ &= \text{endpoint of } q\circ(f\circ\delta) \;=\; (q\circ f)(\delta(1)) \;=\; (q\circ f)(w).\\ &\quad\uparrow \text{ since } q = p^{-1} \text{ we know that } q\circ(f\circ\delta) \text{ is the lift of } f\circ\delta \text{ to the starting point } f(z)\end{aligned}$$

(3) We need to show that $\widetilde{f}$ is a lift, i.e. we need to show that $p\circ\widetilde{f} = f$. So let $z \in Z$. Then

$$p\big(\widetilde{f}(z)\big) \;=\; p\big(\big(\widetilde{f\circ\alpha}\big)(1)\big) \;=\; (f\circ\alpha)(1) \;=\; f(\alpha(1)) \;=\; z.$$

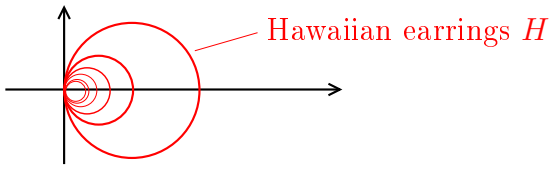
$\uparrow$ pick path α from z_0 to z and denote by $\widetilde{f\circ\alpha}$ the lift of $f\circ\alpha$

■

Proof of the Map Lifting Criterion 61.2 (2). Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected topological space. Finally suppose we are given a map $f\colon (Z, z_0) \to (B, b_0)$.

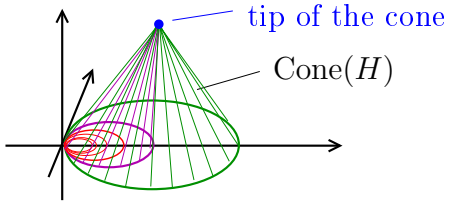
We will now see, using the uniqueness of the lift of paths established in Proposition 48.11, that any two lifts $\widetilde{f}, \widetilde{f}'\colon (Z, z_0) \to (X, x_0)$ agree. Thus let $z \in Z$. Since Z is path-connected there exists a path $\alpha\colon [0,1] \to Z$ from z_0 to z. Then $f\circ\alpha\colon [0,1] \to B$ is a path and $\widetilde{f}\circ\alpha$ and $\widetilde{f}'\circ\alpha$ are both lifts of $f\circ\alpha$ to the starting point x_0. By Proposition 48.11 we have $\widetilde{f}\circ\alpha = \widetilde{f}'\circ\alpha$. In particular the endpoints agree. But this implies the desired statement that $\widetilde{f}(z) = (\widetilde{f}\circ\alpha)(1) = (\widetilde{f}'\circ\alpha)(1) = \widetilde{f}'(z)$. ■

In Exercise 61.3 we will prove the following corollary.



Corollary 61.4. Let $\pi\colon X \to B$ be a covering of topological spaces. Then every open simply connected and locally path-connected subset $U \subset B$ is uniformly covered.

61.3. **Semi-locally simply connected spaces.** Our next goal will be to show that every "reasonable" path-connected non-empty topological spaces admits a covering that is simply connected. To make precise what we mean by "reasonable" we need to introduce the following definition.



Definition. A topological space X is called semi-locally simply connected[716] if for every point $x \in X$ there exists an open[717] neighborhood U of x such that the inclusion induced map $\pi_1(U,x) \to \pi_1(X,x)$ is the trivial map.

Examples.

(1) Every simply connected space is semi-locally simply connected.
(2) Let H be the Hawaiian earring that we introduced on page 1284. In Exercise 61.2 we will see that H is not semi-locally simply connected.
(3) Evidently every topological space that is locally simply connected is also semi-locally simply connected. But the converse does not hold. For example let us consider the cone(H) on the Hawaiian earring.
   (a) By the Cone Contractibility Lemma 16.7 we know that the tip of cone(H) is a deformation retract. This implies that cone(H) is simply connected, in particular it is semi-locally simply connected.
   (b) On the other hand we will see in Exercise 61.2 that cone(H) is not locally simply connected.

not semi-locally simply connected

semi-locally simply connected
but not locally simply connected

61.4. **Existence of covering spaces.** Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces. In Corollary 48.14 we saw that

$$p_*\colon \pi_1(X,x_0) \;\to\; \pi_1(B,b_0)$$

is an injective map. Thus we can view $\pi_1(X,x_0)$ as a subgroup of $\pi_1(B,b_0)$.
Generalizing Question 61.1 one can now ask, whether to each subgroup Γ of $\pi_1(B,b_0)$ there exists a corresponding covering with $p_*(\pi_1(X,x_0)) = \Gamma$. We will see that this is indeed the case, at least under the rather technical assumption that the topological space B is locally path-connected and semi-locally simply connected.
The following theorem gives in particular an affirmative answer to Question 61.1 under rather modest hypotheses.

[716] Note that in contrast to "locally simply connected" there is no general notion of what "semi-locally" means. In other words, we define "semi-locally simply connected" as a single object.
[717] If there exists a neighborhood W of x such that the inclusion induced map $\pi_1(W,x) \to \pi_1(X,x)$ is the trivial map, then the interior U of W is an open neighborhood of x and the inclusion induced map $\pi_1(U,x) \to \pi_1(X,x)$ is trivial, since it factors through the trivial map $\pi_1(W,x) \to \pi_1(X,x)$. Thus in the definition it makes no real difference whether we demand a "neighborhood" or an "open neighborhood".

Theorem 61.5. (Covering Existence Theorem) Let Y be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let $y_0 \in Y$ and let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup.

(1) There exists a path-connected covering[718] $p\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$.
(2) For the covering p from (1) we have

$$[X : Y] \ = [\pi_1(Y, y_0) : \Gamma].$$

We will provide the proof of the Covering Existence Theorem 61.5 in the next section. In the following we discuss a few examples and an important variation on the Covering Existence Theorem 61.5.

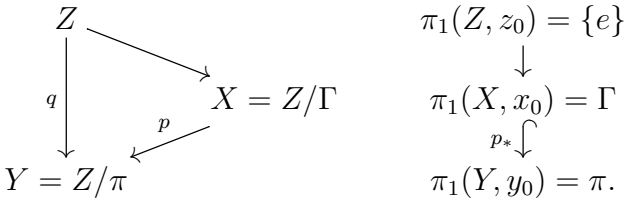
Examples.

(1) We consider $(Y, y_0) = (S^1, 1)$. We pick an identification[719] $\pi_1(S^1, 1) = \mathbb{Z}$. Given $n \in \mathbb{N}$ we consider $\Gamma = n\mathbb{Z} \subset \mathbb{Z} = \pi_1(S^1, 1)$. Then the covering

$$\begin{array}{rcl} p\colon S^1 & \to & S^1 \\ z & \mapsto & z^n \end{array}$$

has the property that $p_*(\pi_1(S^1, 1)) = n\mathbb{Z}$. Another example is given by the covering

$$\begin{array}{rcl} q\colon \mathbb{R}/n\mathbb{Z} & \to & S^1 \\ t + n\mathbb{Z} & \mapsto & \exp(2\pi i t). \end{array}$$



Here we also have $\mathrm{im}(q_*) = n\mathbb{Z}$.

(2) Let Z be a simply connected space and let $z_0 \in Z$. Furthermore let π be a group that acts on Z continuously and discretely. We consider $Y = Z/\pi$, we denote by $q\colon Z \to Y = Z/\pi$ the projection and we write $y_0 = q(z_0)$. Using the isomorphism of the Fundamental Group-via-Actions Theorem 48.16 we can identify π with $\pi_1(Y, y_0)$.

Now let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup. Then the group Γ also acts on Z and we can consider the projection

$$p\colon X := Z/\Gamma \ \to \ Y := Z/\pi$$

We denote by x_0 the image of z_0 under the projection $Z \to X = Z/\Gamma$. One can show easily that $p\colon X = Z/\Gamma \to Y = Z/\pi$ is a covering map with $p_*(\pi_1(X, x_0)) = \Gamma$. We summarize the situation in the following diagram

In the following we apply the Covering Existence Theorem 61.5 to any flavor of a manifold.

[718] Here we say that a covering $p\colon X \to Y$ is path-connected if X is path-connected.

[719] This means that we pick an isomorphism $\pi_1(S^1, 1) \xrightarrow{\cong} \mathbb{Z}$ and then ignore it in the notation.

Proposition 61.6. (Coverings-of-Manifolds Existence Proposition) Let Y be a path-connected topological manifold, let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup.

(1) There exists a path-connected covering $p\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$. Any such X is a topological manifold.
(2) If Y is a smooth manifold, then any cover as in (1) can be equipped with a unique smooth structure such that $p\colon X \to Y$ is a covering of smooth manifolds in the sense of the definition on page 1105.
(3) If Y is a complex manifold, then any cover as in (1) can be equipped with a unique complex structure such that $p\colon X \to Y$ is a covering of complex manifolds.

Proof. First of all note that by the Topological Manifolds-Local Properties Lemma 18.8 we know that topological manifolds are locally contractible. In particular they are locally path-connected and semi-locally simply connected. Thus we obtain from the Covering Existence Theorem 61.5 that there exists a path-connected covering $p\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$ and such that $[X : Y] = [\pi_1(Y, y_0) : \Gamma]$.

The statements regarding smooth and complex manifolds follow immediately from the Manifold Covering Proposition 49.2. ■

61.5. **Proof of the Covering Existence Theorem 61.5.** Now we turn to the proof of the Covering Existence Theorem 61.5. Note that we only need show the existence of such a covering, the statement about the degree of the covering is an immediate consequence of Lemma 48.15 (3).

We start out with a general discussion of the construction of the covering. Only afterwards we will turn to the nitty-gritty of the proof. In particular for the time being let Y be any path-connected topological space, without any other adjectives. Furthermore let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup.

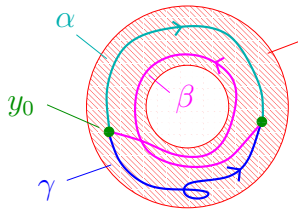
To get an idea for the construction, let us first consider the case that Γ is the trivial group. In this case we want to construct a covering $p\colon X \to Y$ such that X is simply connected. Let us assume for a second, that we have such an X. We pick $x_0 \in X$ with $p(x_0) = y_0$. Then, somewhat similar to the statement of the Fundamental Group-via-Actions Theorem 48.16, we have a map

$$\begin{array}{rcl} \Phi\colon X & \to & \{\text{path-homotopy classes of paths starting in } y_0\} \\ x & \mapsto & p \circ (\text{any path from } x_0 \text{ to } x). \end{array}$$

In fact the proof of the Fundamental Group-via-Actions Theorem 48.16 comes close to showing that the map Φ is a bijection. Hence Φ is in fact a homeomorphism, provided we equip the right-hand side with an appropriate topology.

Now that we are not given X, the idea is, that given (Y, y_0) we can define the right-hand side of the above bijection, and with a suitable topology we will have found our X.

As on page 392 we denote by $Y^{[0,1]}$ the set of all maps $[0, 1] \to Y$. Next we consider the path space[720]



$$P_{y_0} \;:=\; \{\gamma \in Y^{[0,1]} \,|\, \gamma(0) = y_0\} \;=\; \{\text{all paths in } Y \text{ with starting point } y_0\}.$$

[720] On page 3280 the path space will be called $P(Y, y_0)$. Later on it will play an important role, but for the purpose of this discussion it is easier to work with a shorter notation.

For $u, v \in P_{y_0}$ we write

$$u \sim v \quad :\Longleftrightarrow \quad u \text{ and } v \text{ have the same endpoint and } [u * \overline{v}] \in \Gamma.$$

Using the fact that $\Gamma \subset \pi_1(Y, y_0)$ is a subgroup one can show easily that $\sim$ is indeed an equivalence relation on P_{y_0}. The definitions of P_{y_0} and $\sim$ are illustrated in the figure below. We write $X_{y_0,\Gamma} := P_{y_0}/\sim$ and $x_0 := [e_{y_0}]$, i.e. x_0 is the equivalence class of the constant path.

Y is an annulus

we consider $\Gamma = 2\mathbb{Z} \subset \pi_1(Y, y_0) = \mathbb{Z}$,
then α and β are equivalent,
but α and γ are inequivalent

Now we consider the evaluation map

$$\begin{array}{rccc} p\colon X_{y_0,\Gamma} = P_{y_0}/\sim & \to & Y \\ [v] & \mapsto & v(1). \end{array}$$

Note that this map is well-defined, i.e. it is independent of the choice of the representative v. It remains to equip $X_{y_0,\Gamma} = P_{y_0}/\sim$ with a sensible topology and to show that the map $p\colon X_{y_0,\Gamma} = P_{y_0}/\sim \to Y$ has all the desired properties.
In fact in the following we provide two approaches to defining such a topology:

(1) The first one is is "by hand", namely we construct a topology on $X_{y_0,\Gamma} = P_{y_0}/\sim$ from scratch.
(2) The second approach is "off-the-shelves", meaning we make use of the compact-open topology that we introduced on page 392.

Put differently, both Lemma 61.7 and Lemma 61.8 can be used to complete the proof of The Covering Existence Theorem 61.5.
We start out with the "by hand" approach.

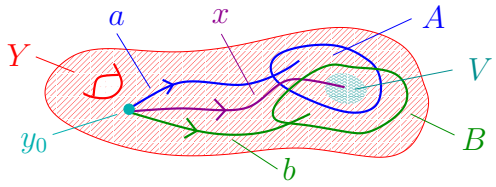
Lemma 61.7. Let Y be a path-connected topological space, let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup. We write $P := P_{y_0}$ and we write $X := X_{y_0,\Gamma}$. Given $x = [f] \in X = P/\sim$ and given an open neighborhood V of $p(x) = f(1) \in Y$ we consider

$$U(x, V) \;:=\; \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1)\} \subset X = P/\sim .$$

With this notation the following statement holds:

(0) The family of all such subsets $U(x, V)$ of X satisfy the "basis property" that we introduced on page 132.

The topology that is generated on $X = X_{Y_0,\Gamma}$ via the sets $U(x, V)$ is called the *whisker topology*. If Y is locally path-connected and semi-locally simply connected, and if we equip $X = X_{Y_0,\Gamma}$ with the whisker topology, then the following statements hold:



(1) The above evaluation map $p\colon X \to Y$ is continuous and open.
(2) The map $p\colon X \to Y$ is a covering.
(3) The topological space X is path-connected,
(4) We have $p_*(\pi_1(X, x_0)) = \Gamma$.

Proof. Let Y be a path-connected, let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup. We write $P := P_{y_0}$ and we write $X := X_{y_0,\Gamma}$. Given $x = [f] \in X = P/\!\sim$ and given an open path-connected neighborhood V of $p(x) = f(1) \in Y$ we consider

$$U(x, V) \;:=\; \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1)\} \subset X = P/\!\sim .$$

We denote by $\mathcal{B}$ the family of all such subsets of X.

(0) We need to show that $\mathcal{B}$ has the basis property.
  (B1) For each $x \in X$ we have $x \in U(x, X)$. This shows that $\mathcal{B}$ satisfies (B1).
  (B2) Now let $x = [f]$ be a point in the intersection of $U(a, A)$ and $U(b, B)$. Let V be any open neighborhood V of $f(1)$ with $V \subset A \cap B$, e.g. we could take $V = A \cap B$. It is straightforward to see that $U(x, V) \subset U(a, A) \cap U(b, B)$.

In the following we assume that Y is locally path-connected and that Y is semi-locally simply connected. We equip $X = X_{Y_0,\Gamma}$ with the *whisker topology*, i.e. we equip it with the topology generated by $\mathcal{B}$. Since Y is locally path-connected it follows easily that the whisker topology is also generated by

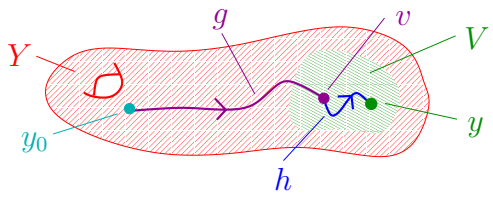
$$\mathcal{C} \;:=\; \{U(x, V) \in \mathcal{B} \,|\, x \in X \text{ and } V \text{ is a } \textit{path-connected} \text{ open neighborhood of } p(x)\}.$$

(1) We need to show that the map $p\colon X = P/\!\sim \to Y$ is continuous and open. We start with the following observation: for every $x \in X$ and every open path-connected neighborhood V of $p(x)$ we have $p(U(x, V)) = V$.[721]

Now we turn to the actual proof of continuity. So let $A \subset Y$ be an open subset and let $x = [f] \in p^{-1}(A)$. It suffices to show that there exists an open subset B of Y such that $U(x, B) \subset p^{-1}(A)$. Since Y is locally path-connected, there exists an open neighborhood B of x that is contained in A and that is path-connected. By the above observation we have $p(U(x, B)) = B \subset A$, i.e. $U(x, B) \subset p^{-1}(A)$.

Finally we show that p is also open. By Lemma 2.11 it suffices to verify that images of the basis $\mathcal{C}$ of the topology of X are open. But this statement we had just verified in the above observation.

(2) Now we want to prove that $p\colon X = P/\!\sim \to Y$ is a covering map. So let $y \in Y$ be a point. We need to show that there exists a connected open neighborhood V of y such that the restriction of p to each component of $p^{-1}(V)$ is a homeomorphism.



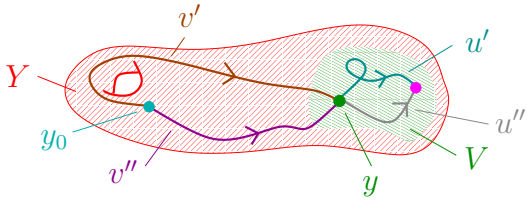
Since Y is semi-locally simply connected, there exists an open neighborhood U of y such that the inclusion induced map $\pi_1(U, x) \to \pi_1(Y, y)$ is the trivial map. We claim that V already has the desired property.

Claim. $$p^{-1}(V) \;=\; \bigsqcup_{\widetilde{y} \in p^{-1}(y)} U(\widetilde{y}, V).$$

[721] By definition we have $p(U(x, V)) \subset V$. But since V is path-connected we also have $V \subset p(U(x, V))$.

Proof. It is clear that the right-hand side is contained in the left-hand side. Next we want to show that the left-hand side is contained in the right-hand side. So let $[g] \in p^{-1}(V)$. Here g is a path in Y from y_0 to a point $v \in V$. Since V is in particular path-connected there exists a path h in V from v to y. We then have

$$[g] \;=\; [g * h * \overline{h}] \;\in\; U(\underbrace{[g * h]}_{\in p^{-1}(y)}, V).$$



It remains to show that the sets on the right-hand side of the claim are disjoint. So let $[v'], [v''] \in p^{-1}(y)$ and let $[g] \in U([v'], V) \cap U([v''], V)$. Then there exist paths u' and u'' in V with $[v' * u'] = [v'' * u'']$. It follows that

$$[v'] \;=\; [v' * u' * \overline{u}'] \;=\; [v'' * u'' * \overline{u}'] \;\underset{\uparrow}{=}\; [v''].$$

$u'' * \overline{u}'$ is null-homotopic since the map $\pi_1(V, y) \to \pi_1(Y, y)$ is the trivial map

Thus $U([v'], V) \cap U([v''], V)$ intersect only if $[v'] = [v'']$. We refer to the figure below for an illustration. ⊞

The sets $U(\widetilde{y}, V)$ are by definition open. By the above claim the sets are also disjoint. Thus it suffices to prove the following claim.

Claim. For each $\widetilde{y} \in p^{-1}(y)$ the restriction of the projection $p\colon X = P/\!\sim \to Y$ to the map $p\colon U(\widetilde{y}, V) \to V$ is a homeomorphism.

Proof. So let $\widetilde{y} \in p^{-1}(y)$. As we had just pointed out in (1), the map $p\colon U(\widetilde{y}, V) \to V$ is surjective. From the fact that the inclusion induced map $\pi_1(V, y) \to \pi_1(Y, y)$ is trivial it also follows immediately that p is injective. Furthermore we had just verified in (1) that p is continuous and open. Therefore $p\colon U(\widetilde{y}, V) \to V$ is a homeomorphism. ⊞

(3) Now we want to show that $X = P/\!\sim$ is path-connected. We start out with the following claim.

Claim. Let $\alpha\colon [0,1] \to Y$ be a path. Then

$$\begin{array}{rcl} \widetilde{\alpha}\colon [0,1] & \to & X = P/\!\sim \\ t & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \alpha(ts) \end{array}\right]. \end{array}$$

is a continuous map.

Proof. By the Subbasis-Continuity Proposition 2.9 it suffices to show that for each $U(x,V)$ in the basis $\mathcal{C}$ of the topology on X the preimage $\widetilde{\alpha}^{-1}(U(x,V))$ is open in $[0,1]$. So suppose we are given $U(x,V)$. We denote by $\{I_j\}_{j\in J}$ the path-components of $\alpha^{-1}(V)$. Since α is continuous each I_j is an open subset of $[0,1]$. Note that for each $j\in J$ we either have[722] $\widetilde{\alpha}(I_j)\subset U(x,V)$ or $\widetilde{\alpha}(I_j)\cap U(x,V)=\varnothing$. It follows that

$$\widetilde{\alpha}^{-1}(U(x,V)) \;=\; \text{union of all the } I_j \text{ with the property that } \widetilde{\alpha}(I_j)\subset U(x,V).$$

Thus we see that $\widetilde{\alpha}^{-1}(U(x,V))$ is a union of open subsets of $[0,1]$, hence the preimage itself is open. ⊞

To show that X is path-connected it suffices to show that for every point $x\in X$ there exists a path in X from $x_0=[e_{y_0}]$ to x. So let $x=[\alpha]\in X$. Then such a path is given by $\widetilde{\alpha}\colon[0,1]\to X$, where $\widetilde{\alpha}$ is defined as in the claim. By the claim $\widetilde{\alpha}$ is indeed continuous.

(4) It remains to show that $p_*(\pi_1(X,x_0))=\Gamma$. Let $g\in\pi_1(Y,y_0)$. We choose a representatives $\alpha\colon[0,1]\to Y$ of g. We consider the following path[723] in $X=P/\!\sim$

$$\begin{array}{rcl} \widetilde{\alpha}\colon [0,1] & \to & X=P/\!\sim \\ t & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \alpha(ts) \end{array}\right]. \end{array}$$

Note that $\widetilde{\alpha}$ is evidently the lift of α to the starting point x_0. Then we have

$$g\in p_*(\pi_1(X,x_0)) \underset{\text{Lemma 48.15 (1)}}{\Leftrightarrow} \widetilde{\alpha} \text{ is a loop} \Leftrightarrow \text{in } X=P/\!\sim \text{ we have } \widetilde{\alpha}(1)=x_0=[e_{y_0}] \underset{\text{definition of } \sim \text{ on } P}{\Leftrightarrow} \alpha\in\Gamma.$$

■

Next we use the "off-the-shelves"-topology, namely we will make use of the compact-open topology. For the reader's convenience we recall the definition from page 392.

Definition. Let Y and A be topological spaces. The compact-open topology on the set Y^A, i.e. on the set of all maps from A to Y, is the topology generated, in the sense of the definition on page 135, by all the sets of the form

$$M(K,U) \;:=\; \{f\in Y^A \mid f(K)\subset U\}$$

where $K\subset A$ is compact and where $U\subset Y$ is open.

Lemma 61.8. Let Y be a path-connected topological space and let $y_0\in Y$. Furthermore let $\Gamma\subset\pi_1(Y,y_0)$ be a subgroup.

(i) We equip $Y^{[0,1]}=$ set of all maps $[0,1]\to Y$ with the compact-open topology.
(ii) We equip $P_{y_0}=\{\gamma\in Y^{[0,1]}\mid\gamma(0)=y_0\}$ with the subspace topology.
(iii) We equip $X_{y_0,\Gamma}=P_{y_0}/\!\sim$ with the quotient topology.

We refer to this topology on $X_{y_0,\Gamma}=P_{y_0}/\sim$ as the *CO-topology* on $X_{y_0,\Gamma}$. We write $X:=X_{y_0,\Gamma}$. If Y is locally path-connected and semi-locally simply connected, then the following statements hold:

(1) The above evaluation map $p\colon X\to Y$ is continuous and open.

[722] This might require a few minutes of thought.
[723] Note that this map is continuous by the claim in (3).

(2) The map $p\colon X \to Y$ is a covering.
(3) The topological space X is path-connected,
(4) We have $p_*(\pi_1(X, x_0)) = \Gamma$.

Proof. Let Y be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup. We write $X := X_{y_0,\Gamma}$ and we equip $X := P/\sim$ with the CO-topology. We make a few preparations:

(i) We consider the maps

$$\begin{array}{ccc} P & \hookrightarrow & Y^{[0,1]} \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle \mathrm{ev},\ f\mapsto f(1)} \\ X = P/\sim & \xrightarrow{\quad p \quad} & Y \end{array}$$

where q is the projection and $\mathrm{ev}\colon Y^{[0,1]} \to Y$ is given by the evaluation at 1. By the Topological-Quotient Proposition 5.15 (1a) we know that q is continuous. Furthermore by the Evaluation Map Proposition 12.4 we know that the map $\mathrm{ev}\colon Y^{[0,1]} \to Y$ is continuous. Thus it follows from Lemma 2.1 (3) and the Topological-Quotient Proposition 5.15 (1b) (2) that the induced map $p\colon X = P/\sim \to Y$ is continuous.

(ii) Since Y is locally path-connected it follows from Lemma 2.39 that the open path-connected subsets of Y form a basis for the topology of Y. Since $[0,1]$ is Hausdorff we obtain from Lemma 12.8 that the sets $M(K,U)$, with $K \subset [0,1]$ compact and U open and path-connected form a basis for the topology of the compact-open topology on $Y^{[0,1]}$.

(iii) Let $x = [f] \in X = P/\sim$ and let V be an open path-connected neighborhood of $p(x) = f(1) \in Y$. As in Lemma 61.7 we consider

$$U(x,V) \ := \ \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1)\} \ \subset \ X = P/\sim .$$

We want to show that $U(x,V)$ is an open subset of X. By definition of the quotient topology we need to show that $q^{-1}(U(x,V))$ is an open subset of P. This statement is easily seen to be a consequence of the following claim.

Claim. Let $g\colon [0,1] \to Y$ be a path with $g(0) = y_0$ and $g(1) \in V$. The set

$$\left\{ h \in P \,\middle|\, \begin{array}{c} \text{there exists a path } u\colon [0,1] \to V \text{ with } u(0) = g(1) \\ \text{such that } h \text{ is path-homotopic to } g * u \end{array} \right\}$$

is an open subset of P.

Proof. Let $h \in P$ be a path that is path-homotopic to $g * u$ for some path $u\colon [0,1] \to V$. Note that it follows from the fact that Y is semi-locally simply connected, together with the Lebesgue Corollary 6.6, that there exists an $n \in \mathbb{N}$ and open subsets $D_1, \ldots, D_n$ of Y with the following properties:
(a) For each $i \in \{0, \ldots, n-1\}$ we have $h([\frac{i}{n}, \frac{i+1}{n}]) \subset D_i$.
(b) For each $i \in \{0, \ldots, n-1\}$ the inclusion induced map $\pi_1(D_i, h(\frac{i}{n})) \to \pi_1(Y, h(\frac{i}{n}))$ is the trivial map.

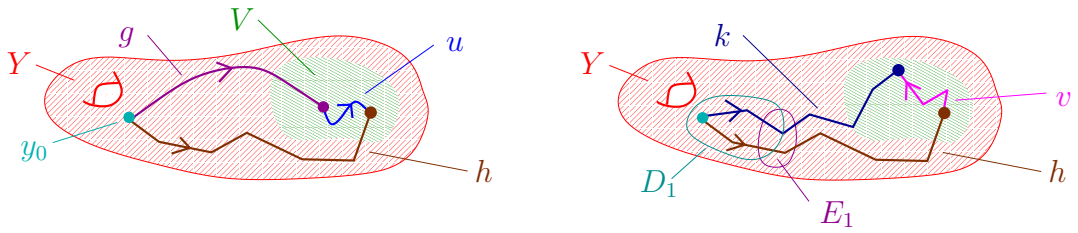
Since Y is locally path-connected we can furthermore find open path-connected neighborhood $E_1, \dots, E_{n-1}$ of $h(\frac{1}{n}), \dots, h(\frac{n-1}{n})$. Now let

$$Z := \bigcap_{i=0}^{n-1} M([\tfrac{i}{n}, \tfrac{i+1}{n}], D_i) \;\cap\; \bigcap_{i=1}^{n-1} M(\{\tfrac{i}{n}\}, E_i) \;\cap\; M(\{1\}, V).$$

We make the following observations:

(α) By definition of the compact-open topology we know that Z is an open subset of $Y^{[0,1]}$. Furthermore it follows from (a) and the choice of $E_1, \dots, E_{n-1}$ that $h \in Z$.

(β) By the JH-Lemma 1.7 it remains to show that $Z \cap P$ is contained in the set that we described in the statement of the claim.



Now let $k \in Z \cap P$.

(γ) Since $k(1) \in V$ and since V is path-connected there exists a path $v\colon [0,1] \to V$ from $h(1)$ to $k(1)$.

(δ) Since the $E_1, \dots, E_{n-1}$ are path-connected we can arrange, after a path-homotopy, that $k(\frac{i}{n}) = (h * v)(\frac{i}{n})$ for $i = 0, \dots, n-1$.

(η) It follows from (b) together with a slight variation on Lemma 47.12 that we can show that k is path-homotopic to $h * v$.

Since k is path-homotopic to $h * v$ and since h is path-homotopic to $g * u$ we have now shown that k is path-homotopic to $g * (u * v)$. But this means that k lies again in the set defined in the statement of the claim. ⊞

(iv) Let $\alpha\colon [0,1] \to Y$ be a path with $\alpha(0) = y_0$. It follows easily from the Compact-Open Exponential Proposition 12.6 and Lemma 2.1 (4) that the map

$$\begin{array}{ccc} [0,1] & \to & P \subset Y^{[0,1]} \\ t & \mapsto & \left(\begin{array}{ccc} [0,1] & \to & Y \\ s & \mapsto & \alpha(ts) \end{array} \right). \end{array}$$

is continuous.

Now we turn to the actual proofs of the four statements.

(1) In (i) we already showed that $p\colon X = P/\!\sim \to Y$ is continuous. We still need to show that p is open. It follows from an elementary argument, see Exercise 5.26, that it suffices to show that the evaluation map $\mathrm{ev} = p \circ q\colon P \to Y$ is open. In fact it follows from (ii), together with Lemmas 1.33 and Lemma 2.11 that it suffices to prove the following claim.

Claim. For each compact subset $K \subset [0,1]$ and each path-connected open subset $V \subset Y$ we have $\mathrm{ev}(M(K,V) \cap P) = V$.

Proof. A straightforward argument, that uses that Y and V are path-connected, shows that

$$\mathrm{ev}(M(K,V)\cap P) \;=\; \begin{cases} \varnothing, & \text{if } M(K,V)=\varnothing,\\ Y, & \text{if } 1\notin K \text{ and } M(K,V)\neq\varnothing,\\ V, & \text{if } 1\in K. \end{cases}$$

Thus we see that in any case the image $\mathrm{ev}(M(K,V))$ is an open subset of Y. ⊞

(2) Now we want to prove that $p\colon X=P/\!\sim\to Y$ is a covering map. So let $y\in Y$ be a point. We need to show that there exists a connected open neighborhood V of y such that the restriction of p to each component of $p^{-1}(V)$ is a homeomorphism.

Since Y is semi-locally simply connected, there exists an open neighborhood V of y such that the inclusion induced map $\pi_1(V,y)\to\pi_1(Y,y)$ is the trivial map. We claim that V already has the desired property.

Claim. $$p^{-1}(V) \;=\; \bigsqcup_{\widetilde{y}\in p^{-1}(y)} U(\widetilde{y},V).$$

Proof. For the reader's convenience we repeat word-by-word the proof from page 1363. First note that it is clear that the right-hand side is contained in the left-hand side. Next we want to show that the left-hand side is contained in the right-hand side. So let $[g]\in p^{-1}(V)$. Here g is a path in Y from y_0 to a point $v\in V$. Since V is in particular path-connected there exists a path h in V from v to y. We then have

$$[g] \;=\; [g*h*\overline{h}] \;\in\; U(\underbrace{[g*h]}_{\in p^{-1}(y)},V).$$

It remains to show that the sets on the right-hand side of the claim are disjoint. So let $[v'],[v'']\in p^{-1}(y)$ and let $[g]\in U([v'],V)\cap U([v''],V)$. Then there exist paths u' and u'' in V with $[v'*u']=[v''*u'']$. It follows that

$$[v'] \;=\; [v'*u'*\overline{u}'] \;=\; [v''*u''*\overline{u}'] \underset{\uparrow}{=} [v''].$$

$u''*\overline{u}'$ is null-homotopic since the map $\pi_1(V,y)\to\pi_1(Y,y)$ is the trivial map

Thus $U([v'],V)\cap U([v''],V)$ intersect only if $[v']=[v'']$. ⊞

By (iii) we know that the sets $U(\widetilde{y},V)$ are open. By the above claim the sets are also disjoint. Thus it suffices to prove the following claim.

Claim. For each $\widetilde{y}\in p^{-1}(y)$ the restriction of the projection $p\colon X=P/\!\sim\to Y$ to the map $p\colon U(\widetilde{y},V)\to V$ is a homeomorphism.

Proof. The proof of this claim is again almost verbatim the same as on page 1363. So let $\widetilde{y}\in p^{-1}(y)$. It follows easily from the fact that V that the map $p\colon U(\widetilde{y},V)\to V$ is surjective. From the fact that the inclusion induced map $\pi_1(V,y)\to\pi_1(Y,y)$ is trivial it also follows immediately that p is injective. Furthermore we had just verified in (1) that p is continuous and open. Therefore $p\colon U(\widetilde{y},V)\to V$ is a homeomorphism. ⊞

(3) It follows from the fact that Y is path-connected together with (iv) that P is path-connected. By the Quotient-Compact Connected Lemma 5.16 (2) this implies that $X=P/\!\sim$ is path-connected.

(4) It remains to show that $p_*(\pi_1(X,x_0))=\Gamma$. The proof we now give is basically identical to the proof on page 1364. Thus let $g\in\pi_1(Y,y_0)$. We choose a representatives

$\alpha\colon [0,1] \to Y$ of g. We consider the following map:

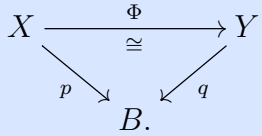
$$\begin{array}{rcl} \widetilde{\alpha}\colon [0,1] & \to & X = P/\!\sim \\ t & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \alpha(ts) \end{array}\right]. \end{array}$$

By (iv) we know that $\widetilde{\alpha}$ is in fact continuous. It is now clear that $\widetilde{\alpha}$ is the lift of α to the starting point x_0. Then we have

$$g \in p_*(\pi_1(X,x_0)) \underset{\uparrow}{\Leftrightarrow} \widetilde{\alpha} \text{ is a loop} \Leftrightarrow \text{in } X = P/\!\sim \text{ we have } \widetilde{\alpha}(1) = x_0 = [e_{y_0}] \underset{\uparrow}{\Leftrightarrow} \alpha \in \Gamma.$$

Lemma 48.15 (1) — definition of $\sim$ on P ■

Remark.



(1) The construction of the universal covering of a topological space has its origin in the work of Hermann Weyl from 1913, see [**Wey1913**][**Wey1964**, p. 58].

(2) Let Y be a path-connected topological space, let $y_0 \in Y$ and let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup. Recall that in Lemma 61.7 we introduced the whisker topology and that in Lemma 61.8 we introduced the CO-topology on $X_{y_0,\Gamma} := P_{y_0}/\!\sim$.
   (a) In [**FZ2007**, Lemma 2.1] it is shown that the CO-topology is contained in the whisker topology.
   (b) In [**FZ2007**, Example 2.2] it is shown that the two topologies are in general not equal, for example they disagree for the Hawaiian earrings that we introduced on page 1284.
   (c) It follows from the Covering Uniqueness Theorem 61.9 (see also [**FZ2007**, Lemma 2.1]) that the two topologies agree for every topological space that is locally path-connected and semi-locally simply connected.

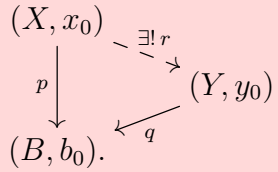
(3) The various choices of topologies on $X_{y_0,\Gamma} = P_{y_0}/\!\sim$ are discussed in greater detail in [**FZ2007, VZ2014**] and [**Pav2020**]. The history of the construction of covering spaces is also outlined [**Pav2020**].

61.6. **Uniqueness of covering spaces.** Now the question arises, to what degree is the covering corresponding to the subgroup Γ unique. To answer that question we need an appropriate notion of two coverings being equivalent.

Definition. Let $p\colon X \to B$ and $q\colon Y \to B$ be two coverings of a topological space B. We say p and q are equivalent, if there exists a homeomorphism $\Phi\colon X \to Y$ such that the following diagram commutes:

Similarly we define the equivalence of coverings of pointed topological spaces.

Example. Given $n \in \mathbb{N}$ the two coverings



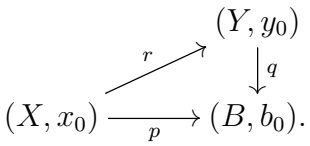
$$\begin{array}{rcl} p\colon S^1 & \to & S^1 \\ z & \mapsto & z^n \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon \mathbb{R}/n\mathbb{Z} & \to & S^1 \\ t + n\mathbb{Z} & \mapsto & \exp(\mathrm{i}t) \end{array}$$

are equivalent. In fact the desired map $\Phi\colon S^1 \to \mathbb{R}/n\mathbb{Z}$ is given by $\exp(2\pi\,\mathrm{i}t) \mapsto [nt]$.

Now we can formulate the following theorem:

Theorem 61.9. (Covering Uniqueness Theorem) Let B be a topological space, let $b_0 \in B$ and let $\Gamma \subset \pi_1(B, b_0)$ be a subgroup.

(1) Let $p\colon (X, x_0) \to (B, b_0)$ be a path-connected and locally path-connected covering such that $p_*(\pi_1(X, x_0)) = \Gamma$. This covering has the following universal property: for any other path-connected covering $q\colon (Y, y_0) \to (B, b_0)$ with $\Gamma \subset q_*(\pi_1(Y, y_0))$ there exists a unique covering $r\colon (X, x_0) \to (Y, y_0)$ such that the following diagram commutes:



(2) If B is path-connected, locally path-connected and semi-locally simply connected, then there exists, up to equivalence, a unique path-connected covering $p\colon (X, x_0) \to (B, b_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$.

Remark. Let B be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let $b_0 \in B$ and let $\Gamma \subset \pi_1(B, b_0)$ be a subgroup. It follows from the Covering Uniqueness Theorem 61.9 that the whisker topology and the CO-topology on the set $X = \{\gamma \in B^{[0,1]} \mid \gamma(0) = b_0\}/\sim$, which we introduced in Lemmas 61.7 and 61.8, are actually the same.

Proof. Let B be a topological space and let $b_0 \in B$.

(1) Let $p\colon (X, x_0) \to (B, b_0)$ and $q\colon (Y, y_0) \to (B, b_0)$ be two path-connected coverings such that $p_*(\pi_1(X, x_0)) \subset q_*(\pi_1(Y, y_0))$. We assume furthermore that X is locally path-connected. It follows from the Map Lifting Criterion 61.2 that there exists a unique map $r\colon (X, x_0) \to (Y, y_0)$ which makes the following diagram commute

It remains to show that r is a covering. This will be done in Exercise 61.5.

(2) The existence of such a covering is just the statement of the Covering Existence Theorem 61.5. The uniqueness statement is an immediate consequence of (1)[724] and the usual proof of uniqueness for an object satisfying a universal property. We leave the details to the reader. ■

The Covering Existence Theorem 61.5 and the Covering Uniqueness Theorem 61.9 (2) lead us to the following definition.

[724] If one does the argument carefully, then one sees, that here we use the following fact: if B is locally path-connected, then also every covering space of B is locally locally path-connected.

Definition. Let B be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let $b_0 \in B$ and let $\Gamma \subset \pi_1(B, b_0)$ be a subgroup.

(1) As in the proof of the Covering Existence Theorem 61.5 we consider the set

$$\widetilde{B}^{\Gamma}_{b_0} \;:=\; \{\text{all paths in } B \text{ with starting point } b_0\}/\!\sim$$

where $u \sim v$ if and only u and v have the same endpoint and if $[u * \overline{v}] \in \Gamma$. We equip the set $\widetilde{B}^{\Gamma}_{b_0}$ with the topology introduced in the proof of the Covering Existence Theorem 61.5. We refer to $\widetilde{B}^{\Gamma}_{b_0}$ together with map $p\colon \widetilde{B}^{\Gamma}_{b_0} \to B$ given by $[u] \mapsto u(1)$ as the natural covering corresponding to (B, b_0, Γ). Furthermore we refer to the point in $\widetilde{B}^{\Gamma}_{b_0}$ that is represented by the constant path as the natural base point of $\widetilde{B}^{\Gamma}_{b_0}$.

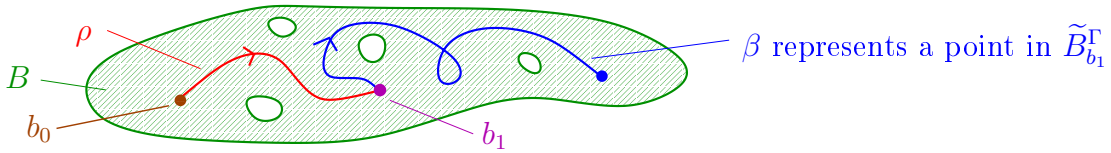
(2) If $\Gamma = \{e\}$ is the trivial subgroup of $\pi_1(B, b_0)$, then we write $\widetilde{B}_{b_0} := \widetilde{B}^{\Gamma}_{b_0}$ and we refer to $p\colon \widetilde{B}_{b_0} \to B$ as the natural universal covering of (B, b_0).

(3) We refer to any path-connected covering $p\colon (X, x_0) \to (B, b_0)$ of pointed topological spaces with $p_*(\pi_1(X, x_0)) = \Gamma$ as a covering of B corresponding to Γ. By the Covering Uniqueness Theorem 61.9 (2) any two such coverings are equivalent, in particular any such covering is equivalent to the above natural covering. In practice usually we do not care about this indeterminacy.

The Covering Uniqueness Theorem 61.9 can be viewed as a "machine" that constructs covering spaces of a given topological space X. In the next section we discuss the case that X is a surface in somewhat greater detail to get a better feeling for what is happening.

Example. Let M be a connected smooth manifold and let $x_0 \in M$. On page 1114 we introduced the orientation character $w_1\colon \pi_1(M, x_0) \to \mathbb{Z}_2$. It follows from the Orientation Covering-Proposition 49.5 that the covering of M corresponding to $\ker(w_1)$ is equivalent to the orientation covering that we introduced on page 1109.

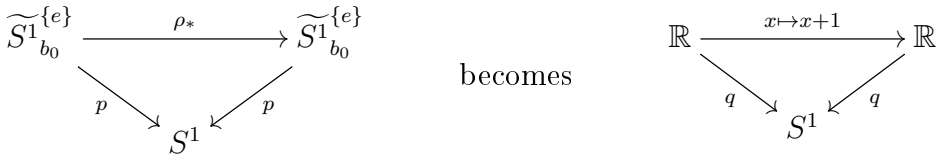
Let B be a topological space and let $\rho\colon [0,1] \to B$ be a path from a point $b_0 = \rho(0)$ to a point $b_1 = \rho(1)$. In the Change-of-Base Point Proposition 47.10 we saw that ρ induces an isomorphism



$$\begin{array}{rcl} \rho_*\colon \pi_1(B, b_1) & \to & \pi_1(B, b_0) \\ [\alpha] & \mapsto & [\rho * \alpha * \overline{\rho}] \end{array}$$

The following lemma now shows that ρ also induce a homeomorphism of natural coverings.

Lemma 61.10. Let B be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let $\rho\colon [0,1] \to B$ be a path from a point $b_0 = \rho(0)$ to a point $b_1 = \rho(1)$. Finally let $\Gamma \subset \pi_1(B, b_1)$ be a subgroup. The map

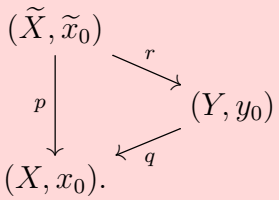


$$\begin{array}{rcl} \rho_*\colon \widetilde{B}^{\Gamma}_{b_1} & \to & \widetilde{B}^{\rho_*(\Gamma)}_{b_0} \\ [\beta] & \mapsto & [\rho * \beta] \end{array}$$

is a homeomorphism.

Proof. One can easily verify that the map $\rho_*\colon \widetilde{B}^{\Gamma}_{b_1} \to \widetilde{B}^{\rho_*(\Gamma)}_{b_0}$ is well-defined and that it is continuous. An inverse is given by the map $\overline{\rho}_*$, which shows that the map ρ_* is indeed a homeomorphism. ■

Example. The map defined in Lemma 61.10 is also interesting if $b_0 = b_1$ and if ρ is a loop in (B, b_0). Let us consider $B = S^1 \subset \mathbb{C}$ with base point $b_0 = 1 = \exp(0\mathrm{i})$ and the trivial subgroup $\Gamma = \{1\} \subset \pi_1(S^1, 1)$. It follows from the Covering Uniqueness Theorem 61.9 that the natural covering $p\colon \widetilde{S^1}^{\{e\}}_{b_0} \to S^1$ is equivalent to the usual covering $q\colon \mathbb{R} \to S^1$ that is given by $q(t) = \exp(2\pi\,\mathrm{i}t)$. In fact they can become equivalent via the homeomorphism $\mathbb{R} \to \widetilde{S^1}^{\{e\}}_{b_0}$ that sends $x \in \mathbb{R}$ to the path $[0,1] \to S^1$ that is given by $t \mapsto \exp(2\pi\,\mathrm{i}tx)$. Now let $\rho\colon [0,1] \to S^1$ be the loop that is given by $t \mapsto \exp(2\pi\,\mathrm{i}t)$. One can now easily show that under the homeomorphism Φ the map



In summary we see that ρ_* acts non-trivially on $\widetilde{S^1}^{\{e\}}_{b_0}$. We will explore this action of loops on natural coverings in much greater detail in the subsequent Chapter 62 on the deck transformation group of coverings.

61.7. **The universal covering.** In the Covering Uniqueness Theorem 61.9 we saw that subgroups of fundamental groups give rise to covering spaces. An obvious choice of a subgroup is the trivial group and we immediately obtain the following corollary to the Covering Uniqueness Theorem 61.9.

Corollary 61.11. Let X be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let $x_0 \in X$. Then the following holds:

(1) There exists, up to equivalence, a unique path-connected covering
$$p\colon (\widetilde{X}, \widetilde{x}_0) \;\to\; (X, x_0)$$
such that $\widetilde{X}$ is simply connected.

(2) Let $q\colon (Y, y_0) \to (X, x_0)$ be another path-connected covering. Then there exists a unique covering $r\colon (\widetilde{X}, \widetilde{x}_0) \to (Y, y_0)$ such that the following diagram commutes:

Proof. Let X be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $x_0 \in X$.

(1) We just apply the Covering Uniqueness Theorem 61.9 to the trivial subgroup of $\pi_1(X, x_0)$ and we obtain, up to equivalence, a unique path-connected covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ such that $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$ is the trivial group. But then it follows from Corollary 48.14 that $\widetilde{X}$ is simply connected.

(2) The second statement is also an immediate consequence of the Covering Uniqueness Theorem 61.9. ■

Definition. Let X be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $x_0 \in X$.

(1) We refer to the natural covering $p\colon \widetilde{X}_{x_0} := \widetilde{X}_{x_0}^{\{e\}} \to X$, as defined on page 1370, as the natural universal covering of (X, x_0).

(2) We refer to any covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ such that $\widetilde{X}$ is simply connected as a universal covering of (X, x_0). As we remarked in the definition on page 1370, very often we suppress the fact that the universal covering is well-defined only up to equivalence.[725]

(3) Sometimes we ignore base points and we say that a covering $p\colon \widetilde{X} \to X$ is the universal covering if $\widetilde{X}$ is simply connected.

Remark. Note that most "reasonable" topological spaces are locally path-connected and semi-locally simply connected. For example we saw on page 1352 that every topological manifold is locally simply connected, which implies in particular that it is locally path-connected and semi-locally simply connected. Thus, given a path-connected topological manifold we can talk of is universal covering.

Examples.

(1) The map

$$\begin{array}{rcl} p\colon \mathbb{R} & \to & \mathbb{R}/\mathbb{Z} = S^1 \\ t & \mapsto & \exp(2\pi\,\mathrm{i}t) \end{array}$$

is the universal covering of S^1.

(2) More generally, the map

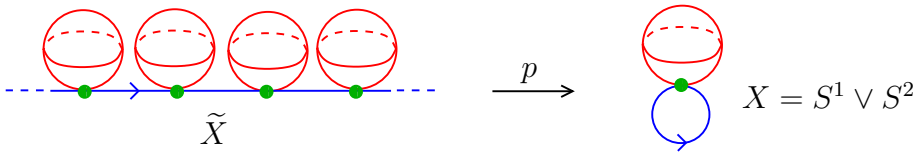
$$\begin{array}{rcl} p\colon \mathbb{R}^n & \to & (S^1)^n \\ (t_1, \ldots, t_n) & \mapsto & \big(\exp(2\pi\,\mathrm{i}t_1), \ldots, \exp(2\pi\,\mathrm{i}t_n)\big) \end{array}$$

is the universal covering of the n-dimensional torus $(S^1)^n$.

(3) The projection $p\colon S^3 \to S^3/\mathbb{Z}_p = L(p, q)$ is the universal covering of the lens space $L(p, q)$.

Remark. The universal covering is often also just called the *universal cover*. Also very often one suppresses the actual map p from the notation. For example, often one says that "$\mathbb{R}^n$ is the universal covering of $(S^1)^n$". The name "universal cover(ing)" stems from the fact, proved in Corollary 61.11, that the universal cover(ing) of a topological space X "covers" every other covering of X.

[725] In the literature the universal covering of a topological space is usually indicated by the same symbol but decorated with a tilde, e.g. the universal covering of X is usually denoted by $\widetilde{X}$.

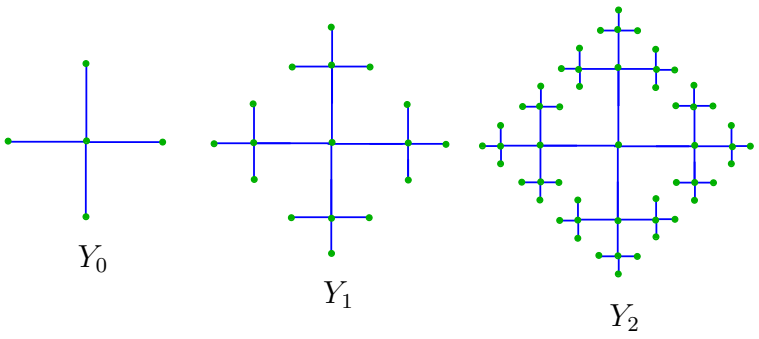


We have now shown that for every topological space X that is locally path-connected and semi-locally simply connected there exists a universal covering $p\colon \widetilde{X} \to X$. So far we have given an abstract construction, but if possible we would like to visualize it. We have just given an explicit description of the universal covering of the n-dimensional torus $(S^1)^n$ and the lens spaces. Now we will describe the universal covers of $X = S^1 \vee S^2$ and $X = S^1 \vee S^1$. First we consider $X = S^1 \vee S^2$ where we identify $i \in S^1$ with $(0,0,-1) \in S^2$. As on page 1175 we consider the topological space

$$\widetilde{X} \;=\; \big(\mathbb{R} \cup (\mathbb{Z} \times S^2)\big) \,/\, n \sim (n,(0,0,-1)), \quad n \in \mathbb{Z}.$$

It is straightforward to see that the map

$$p\colon \big(\mathbb{R} \cup (\mathbb{Z} \times S^2)\big) \,/\, n \sim (n,(0,0,-1)) \to S^1 \vee S^2$$
$$P \;\mapsto \begin{cases} \exp(\mathrm{i}(2\pi P + \frac{\pi}{2})), & \text{if } P \in \mathbb{R} \\ Q, & \text{if } P = (n,Q) \text{ with } n \in \mathbb{Z}, Q \in S^2 \end{cases}$$



is well-defined and in fact a covering. We saw on page 1175 that $\widetilde{X}$ is simply connected. Thus $p\colon \widetilde{X} \to X$ is the universal covering of X.

Now we turn to $X = S^1 \vee S^1$. In the following we give a semi-rigorous description of the universal covering of $S^1 \vee S^1$ as a subset of $\mathbb{R}^2$. Iteratively we build a sequence of topological spaces Y_k, $k \in \mathbb{N}_0$ as follows:

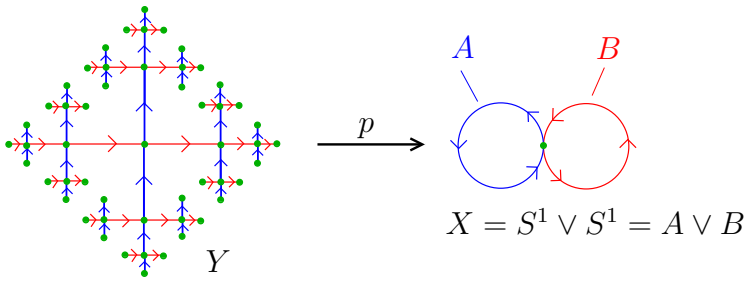
(1) The topological space Y_0 is the cross centered at the origin where each segment has length 1.
(2) Given Y_k we attach to each endpoint of Y_k three segments of length $\frac{1}{4^k}$[726] such that each endpoint of Y_k now has a neighborhood that is a cross. We denote the resulting space by Y_{k+1}.

Finally we put $Y = \bigcup_{k \in \mathbb{N}_0} Y_k$.

We summarize some of the key properties of the construction in the following claim.

Claim.

[726] In the figures the lengths of the segments is $\frac{1}{2^k}$ since these are easier to draw.



(1) Each Y_k is a tree.[727]
(2) Y is simply connected.

Sketch of proof. First note that $\chi(Y_0) = 5 - 4 = 1$. For $k \geq 1$ we obtain Y_k from Y_{k-1} by adding three vertices and three edges, hence $\chi(Y_k) = \chi(Y_{k-1}) = \cdots = \chi(Y_0) = 1$. This shows that each Y_k is a tree. It follows from Proposition 50.14 that each Y_k is simply connected.

Given $k \in \mathbb{N}$ we denote by U_k the result of removing the 4^{k+1} endpoints of Y_k. Note that each U_k is open in Y_k, hence each U_k is open in Y. Furthermore each U_k deformation retracts to Y_{k-1}. Hence it follows from the fact that each Y_k is simply connected that also each U_k is simply connected.

It follows as in Lemma 52.6 that $Y = \bigcup_{k\in\mathbb{N}} Y_k = \bigcup_{k\in\mathbb{N}} U_k$ itself is simply connected. ■

Now we construct a covering $p\colon Y \to S^1 \vee S^1$. To distinguish the two copies of S^1 we name them A and B, which are wedged together along $a \in A$ and $b \in B$. We give both A and B the usual counterclockwise orientation. Furthermore we orient each edge of the infinite topological graph Y as indicated in the figure below. We consider the map $p\colon Y \to A \vee B$

that is given as follows:

(1) each vertex of the infinite topological graph Y gets sent to the point $a = b \in A \vee B$,
(2) each horizontal edge of Y gets sent in an orientation-preserving way to $A \setminus \{a\}$,
(3) each vertical edge of Y gets sent in an orientation-preserving way to $B \setminus \{b\}$.

This map is illustrated in the figure above. It is relatively straightforward to convince oneself that $p\colon Y \to X$ is in fact a covering.[728] Since Y is simply connected, this is the universal covering of $X = A \vee B = S^1 \vee S^1$.

We have now determined explicitly the universal covers of several topological spaces. The surfaces of genus $g \geq 2$ are arguably one of the most interesting types of topological manifolds. Therefore it is natural to ask the following question.

Question 61.12. What does the universal covering of the surface of genus $g \geq 2$ look like?

We continue with the following proposition which will prove helpful at times.

---

[727] Recall that by definition a tree is a topological graph with finitely many vertices V and edges E, such that the Euler characteristic $\chi(G) = \#V - \#E = 1$.

[728] We have to check that each point in $X = A \vee B$ admits an open neighborhood that is uniformly covered. It is clear that such a point exists for all points that are not the wedge point. For the wedge point itself the desired open neighborhood is given by small open intervals on A and B. Then each component of the preimage consists of a little cross with center P, with one horizontal edge going into P, one horizontal edge going out of P, one vertical edge going into P and one vertical edge going out of P.

Proposition 61.13. (Lift-to-Universal Coverings Proposition) Let X and Y be topological spaces that are path-connected, locally path-connected and semi-locally simply connected. Let $p\colon \widetilde{X} \to X$ and $q\colon \widetilde{Y} \to Y$ be universal coverings. Finally suppose we are given a map $f\colon X \to Y$ and points $x_0 \in X$, $\widetilde{x}_0 \in \widetilde{X}$ and $\widetilde{y}_0 \in \widetilde{Y}$ with $p(\widetilde{y}_0) = f(x_0)$.

(1) There exists a unique map $\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}$ with $\widetilde{f}(\widetilde{x}_0) = \widetilde{y}_0$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{f} & Y. \end{array}$$

(2) If f is a homeomorphism, then $\widetilde{f}$ is also a homeomorphism.

(3) Suppose that X and Y are smooth manifolds and that p and q are coverings of smooth manifolds.[729]

(a) If f is smooth (respectively a diffeomorphism), then f is also smooth (respectively a diffeomorphism). The analogous statement also holds for complex manifolds.

(b) If X and Y are oriented, and if p and q are orientation-preserving, then f is orientation-preserving if and only if $\widetilde{f}$ are orientation-preserving.

Remark.

(1) the Lift-to-Universal Coverings Proposition 61.13 is a generalization of Exercise 49.2 (a).

(2) In Proposition 62.13 we will prove that the map $\widetilde{f}$ has an interesting extra property.

Proof.

(1) We consider the map $f \circ g := p\colon \widetilde{X} \to Y$. Since $\widetilde{Y}$ is the universal covering, since $\pi_1(\widetilde{X}, \widetilde{x}_0)$ and since X is locally path-connected and semi-locally simply connected we obtain from the Map Lifting Criterion 61.2 that there exists a unique lift $\widetilde{g}\colon \widetilde{X} \to \widetilde{Y}$ of g with $\widetilde{g}(\widetilde{x}_0) = \widetilde{y}_0$. This map is precisely the map we were trying to find.

(2) This statement follows easily from the uniqueness statement of (1). We will fill in the details in Exercise 61.11.

(3) Note that coverings of smooth manifolds are in particular local diffeomorphisms. The statement now follows easily from (1) and (2), together with the Smooth Pasting Proposition 19.23. The case of complex manifolds is treated in almost entirely the same way. ■

We conclude this section with a more general statement. Recall that in the Fundamental Group-via-Actions Theorem 48.16 we saw that if X is a simply connected space and if G is a group that acts continuously and discretely on X, then the fundamental group of the quotient space X/G is isomorphic to G. Now we will show that, under modest extra hypotheses, the converse holds. More precisely, we have the following proposition.

Proposition 61.14. p Let Y be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $y_0 \in Y$. We write $\pi = \pi_1(Y, y_0)$. Then there exists a simply connected space X, namely the universal covering of Y, and a continuous and discrete action of π on X such that Y is homeomorphic to X/π.

[729] We refer to page 1105 for the definition of a covering between smooth manifolds.

Proof. Let Y be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $y_0 \in Y$ be a base point. In the Covering Existence Theorem 61.5 we already showed that Y admits a simply connected covering. We recall the explicit construction given in the proof of the Covering Existence Theorem 61.5. Thus we consider

$$P \;:=\; \{f \in Y^{[0,1]} \,|\, f(0) = y_0\} \;=\; \{\text{all paths in } Y \text{ with starting point } y_0\}.$$

For $u, v \in P$ we write

$$u \sim v \quad :\Leftrightarrow \quad u \text{ and } v \text{ have the same endpoint and } [u * \overline{v}] = e \in \pi_1(Y, y_0)$$

and we put $X = P/\sim$. As in Lemma 61.7 given $x = [f] \in X = P/\sim$ and an open path-connected neighborhood V of $f(1)$ we define

$$U(x, V) \;:=\; \{[f * u] \,|\, u \text{ is a path in } V \text{ with starting point } f(1)\} \;\subset\; X = P/\sim .$$

Furthermore, as in Lemma 61.7 we endow X with the whisker topology, i.e. with the topology generated by these sets $U(x, V)$.

Claim. The map

$$\begin{array}{rcl} \pi_1(Y, y_0) \times X & \to & X \\ ([g], [u]) & \mapsto & [g * u] \end{array}$$

is a well-defined action.

Proof. We first show that the map is independent of the choice of u. So suppose that $u, v \in P$ are equivalent. Then $g * u$ and $g * v$ still have the same endpoint. Now we need to consider the second condition in the definition of $\sim$. We have

$$[(g * u) * (\overline{g * v})] \;=\; [g * u * \overline{v} * \overline{g}] \;=\; [g] * \underbrace{[u * \overline{v}]}_{= e \in \pi_1(Y, y_0)} * [g]^{-1} \;=\; e \;\in \pi_1(Y, y_0).$$

It is straightforward to see that the map does not depend on the choice of representative g. Finally we want to show that it is indeed an action. So let $[g], [h] \in \pi_1(Y, y_0)$. Then

$$[g] \cdot ([h] \cdot [u]) \;=\; [g] \cdot [h * u] \;=\; [g * (h * u)] \;=\; [(g * h) * u] \;=\; [g * h] \cdot [u] \;=\; ([g] \cdot [h]) \cdot [u].$$

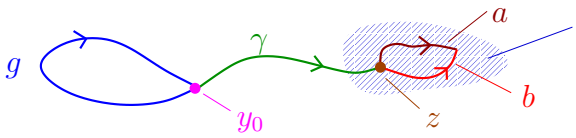
⊞

Now we need to show the following:

(1) the group $\pi_1(Y, y_0)$ acts continuously and discretely on $X = P/\sim$,
(2) there exists a homeomorphism $f\colon X/\pi_1(Y, y_0) \to Y$.

We do this in the following two steps:

(1) It follows immediately from the definition of the whisker topology on $X = P/\sim$ and from the Subbasis-Continuity Proposition 2.9 that the action is continuous.



Now we need to show that the action is discrete. So let $x = [\gamma] \in P/\sim$. We set $z := \gamma(1) \in Y$. Since Y is semi-locally simply connected there exists an open neighborhood V of $z = \gamma(1)$ such that the inclusion induced map $\pi_1(V, z) \to \pi_1(Y, z)$ is trivial. It suffices to show that for $[g] \in \pi_1(Y, y_0)$ we have

$$[g] \cdot U(x, V) \cap U(x, V) \neq \varnothing \quad \Longrightarrow \quad [g] = e \in \pi_1(Y, y_0).$$

So suppose that $[g] \cdot U(x, V) \cap U(x, V) \neq \varnothing$. This means that there exist paths a and b in U, starting from P such that $g * \gamma * a$ and $\gamma * b$ have the same endpoint and

they are path-homotopic in Y. But then

$$[g] \;=\; [g]\cdot\underbrace{[\gamma]\cdot\overbrace{[a*\bar{b}]}^{=e\in\pi_1(Y,y_0)=\{e\}}*[\gamma]^{-1}}_{=e\in\pi_1(Y,y_0)} \;=\; [(g*\gamma*a)*\overline{(\gamma*b)}] \;=\; e\;\in\;\pi_1(Y,y_0).$$

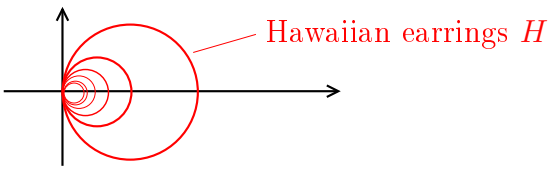
open neighborhood V of z such that $\pi_1(V,z)\to\pi_1(Y,z)$ is trivial

(2) We consider the map

$$\begin{array}{rcl} f\colon X/\pi_1(Y,y_0) & \to & Y \\ [\gamma] & \mapsto & \gamma(1). \end{array}$$

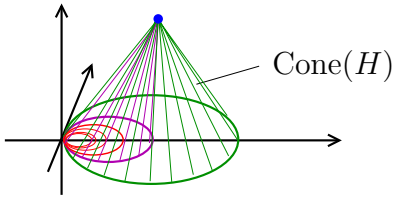
It is straightforward to see that this map is a bijection. It follows immediately from the Topological-Quotient Proposition 5.15 (1b) that the map is continuous and it follows from Lemma 2.11 that the map is open. Thus it is a homeomorphism. ■

Exercises for Chapter 61.



Exercise 61.1.

(a) Show that every topological graph is locally contractible.
(b) Let $\{X_i\}_{i\in I}$ be a family of locally contractible topological spaces. Show that any wedge $\bigvee_{i\in I} X_i$ is also locally contractible.



Remark. For a rigorous argument you will want to use the Homotopy Quotient Theorem 14.7.

Exercise 61.2. Let H be the Hawaiian earring that we introduced on page 1284 and that we show in the figure below to the left.

(a) Show that H is not semi-locally simply connected.
(b) Show that cone(H) is not locally simply connected.

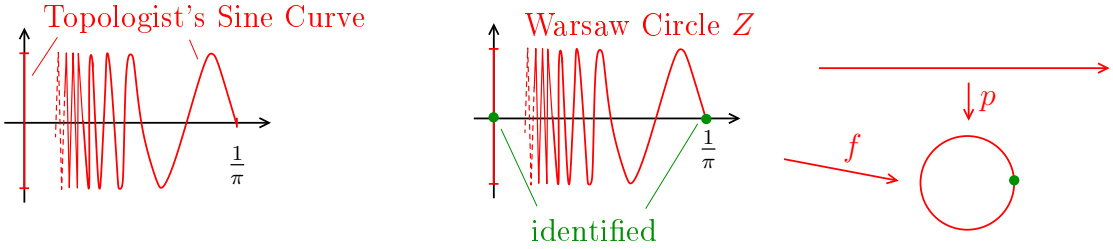
not semi-locally simply connected

not locally simply connected

Exercise 61.3. Let $\pi\colon X\to B$ be a covering of topological spaces. Show that every simply connected and locally path-connected subset $U\subset B$ is uniformly covered.

Exercise 61.4. On page 164 we introduced the Topologist's Sine Curve

$$X \;:=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\}\cup\big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\}\;\subset\;\mathbb{R}^2.$$



As on page 276 we refer to quotient space $Z := X/(0,0) \sim (\frac{1}{\pi}, 0)$ as the *Warsaw Circle*. We consider the map

$$\begin{array}{rcl} f\colon Z & \to & S^1 \\ [(x,y)] & \mapsto & \exp(2\pi^2 \cdot x \cdot \mathrm{i}) \end{array} \qquad \text{and the covering map} \qquad \begin{array}{rcl} p\colon \mathbb{R} & \to & S^1 \\ t & \mapsto & \exp(t \cdot \mathrm{i}). \end{array}$$

(a) Show that $f\colon Z \to S^1$ is continuous.

(b) Show that there is no continuous map $\widetilde{f}\colon Z \to \mathbb{R}$ with $p \circ \widetilde{f} = f\colon Z \to S^1$.

Remark. This Exercise shows that in the Map Lifting Criterion 61.2 we cannot drop the hypothesis that Z is locally path-connected.

Exercise 61.5. Let $p\colon (X, x_0) \to (B, b_0)$ and $q\colon (Y, y_0) \to (B, b_0)$ be two path-connected coverings of topological spaces such that $p_*(\pi_1(X, x_0)) \subset q_*(\pi_1(Y, y_0))$. It follows from the Map Lifting Criterion 61.2 that there exists a unique map $r\colon (X, x_0) \to (Y, y_0)$ which makes the following diagram commute

$$\begin{array}{ccc} & & (Y, y_0) \\ & \overset{r}{\nearrow} & \downarrow q \\ (X, x_0) & \xrightarrow[p]{} & (B, b_0). \end{array}$$

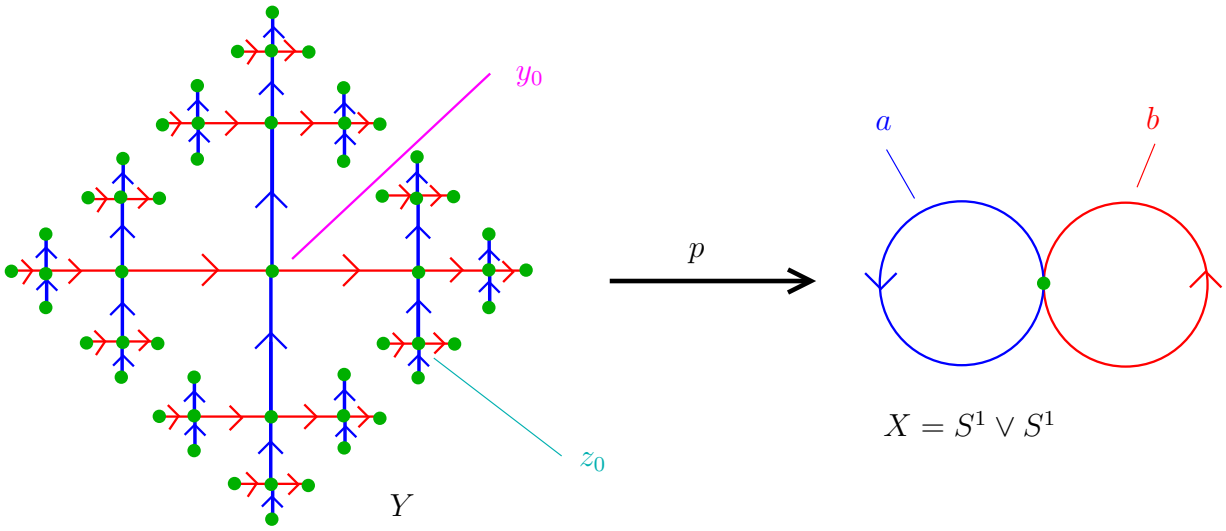
Show that r is a covering.

Exercise 61.6. We consider the figure below.

(a) Let X be the wedge of two circles and let $p\colon Y \to X$ be the universal covering that is illustrated in the figure. Denote the usual generators of $\pi_1(X)$ by a and b. By an abuse of notation we denote by a and b also representing loops. What does the lift of the loop $a * b * \overline{a} * \overline{b}$ to Y to the starting point y_0 look like?

(b) We continue with the notation from (1). Now consider the loop

$$\gamma := a * a * b * a * a * \overline{b} * \overline{a} * b * b * \overline{a} * \overline{a} * \overline{b} * \overline{a} * \overline{b}.$$



We denote by $\widetilde{\gamma}$ the lift of γ to the starting point y_0. Is y_0 the endpoint of $\widetilde{\gamma}$?

(c) Does there exist a homeomorphism $f\colon Y \to Y$ with $f(y_0) = z_0$?

Exercise 61.7. Let $X = S^1 \cup \{*\}$ be $S^1 = \{z \in \mathbb{C} \,|\, |z| = 1\}$ with two "1", where the topology is defined as for the line with two zeros, see page 122. Does X admit a universal cover? If yes, can you describe it explicitly?

Exercise 61.8.

(a) Let M be the Möbius band. We pick an identification $\pi_1(M) = \mathbb{Z}$. Given $k \in \mathbb{N}$ we denote by Γ_k the kernel of the epimorphism $\pi_1(M) = \mathbb{Z} \to \mathbb{Z}_k$. Let $M_k \to M$ be the

covering corresponding to Γ_k. What well-known topological space is M_k? You do not have to justify your answer.

(b) Draw the universal covering of $\mathbb{R}\mathrm{P}^2 \vee S^1$ as a subset of $\mathbb{R}^3$.

(c) Let $X = A \vee B$ be the wedge of two circles. Let $\Gamma \subset \pi_1(X) = \langle a, b \rangle$ be the commutator subgroup. What does the covering $p\colon \widetilde{X} \to X$ corresponding to Γ look like? You can draw it as a subset of $\mathbb{R}^2$.
Hint. You have seen $\widetilde{X}$ many times in your life.

Exercise 61.9. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. We denote by $M := \mathrm{Tor}(X, f) := (X \times [0,1])/(x,0) \sim (f(x),1)$ the corresponding mapping torus (see page 467.) Let $p\colon \widetilde{M} \to M$ be a finite covering. Show that $\widetilde{M}$ is homeomorphic to a mapping torus.

Exercise 61.10. We say two smooth manifolds M and N are *commensurable* if M and N admit finite covers $\widetilde{M}$ and $\widetilde{N}$ that are diffeomorphic.

(a) Show that the torus and the surface of genus two are not commensurable.

(b) Let $g, h \in \mathbb{N}_{n\geq 2}$. Let M be the surface of genus g and let N be the surface of genus h. Show that M and N are commensurable.

(c) Determine which compact connected 2-dimensional smooth manifolds are commensurable.

Exercise 61.11. Let X be a topological space and let $p\colon \widetilde{X} \to X$ be a covering. Let $f\colon X \to X$ be a homeomorphism and let $\widetilde{f}\colon \widetilde{X} \to \widetilde{X}$ be a map such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{X} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{f} & X. \end{array}$$

Show that $\widetilde{f}$ is also a homeomorphism.
Remark. This is a generalization of Exercise 49.2 (b).

Exercise 61.12. Give an example of a topological space X, a finite covering $p\colon \widetilde{X} \to X$ and a homeomorphism $f\colon X \to X$ which does *not* lift to a map $\widetilde{f}\colon \widetilde{X} \to \widetilde{X}$, i.e. such there is no map $\widetilde{f}\colon \widetilde{X} \to \widetilde{X}$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{X} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{f} & X. \end{array}$$

Exercise 61.13. Let X be a path-connected topological space that is locally path-connected and let $p\colon \widetilde{X} \to X$ be a finite covering of degree d.

(a) Let $f\colon X \to X$ be a homeomorphism. Show that there exists a map $\widetilde{f}\colon \widetilde{X} \to \widetilde{X}$ such that $p \circ \widetilde{f} = f^d \circ p$.

(b) Does the conclusion of (a) also hold, if we do not assume that f is a homeomorphism?

Exercise 61.14. Let X be a path-connected topological space that is locally path-connected and semi-locally simply connected. Furthermore let $x_0 \in X$. By the Covering Uniqueness Theorem 61.9 there exists an, essentially unique, covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$. We refer this covering as the *universal abelian covering of* (X, x_0).

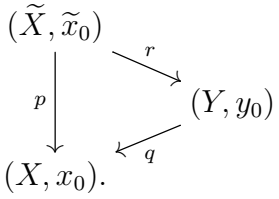
(a) Let X be torus minus one open disk. Give an explicit description of the universal abelian cover of X.

(b) Let X be the sphere minus three open disks. Give an explicit description of the universal abelian cover of X.

Evidently the expression "explicit" is a little vague, you could interpret it as an explicit description as a submanifold of say $\mathbb{R}^3$.

Exercise 61.15. Let $f\colon (X, x_0) \to (Y, y_0)$ be a map between pointed topological spaces such that $f_*\colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$ is a monomorphism. We assume that both X and Y are locally path-connected and semi-locally simply connected. Let Γ be a subgroup of $\pi_1(Y, y_0)$ Let $q\colon \widetilde{Y} \to Y$ be the covering corresponding to Γ. Show that the pullback $p\colon f^*\widetilde{Y} \to X$, as defined in the Topological-Pullback Lemma 56.16, is the covering corresponding to the subgroup $f_*^{-1}(\Gamma)$ of $\pi_1(X, x_0)$.

Exercise 61.16. Let X be a path-connected topological space that is locally path-connected and that is semi-locally simply connected. Furthermore let $p\colon \widetilde{X} \to X$ be the universal covering. Let $x_0 \in X$ be a base point and let $\varphi\colon \pi_1(X, x_0) \to \Gamma$ be a group homomorphism. We consider



$$\begin{array}{rcl} q\colon \widetilde{X}_\varphi := (\widetilde{X} \times \Gamma)/\overbrace{(x,g) \sim (h \cdot x, \varphi(h) \cdot g)}^{x \in X, g \in \Gamma \text{ and } h \in \pi_1(X,x_0)} & \to & X \\ [(x,g)] & \mapsto & p(x) \end{array}$$

where we equip Γ with the discrete topology, $\widetilde{X} \times \Gamma$ with the product topology and $\widetilde{X}_\varphi$ with the quotient topology.

(a) Suppose that φ is an epimorphism. Show that $q\colon \widetilde{X}_\varphi \to X$ is the covering corresponding to $\ker(\varphi)$.

(b) In general, show that the number of components of $\widetilde{X}_\varphi$ has the same cardinality as $\operatorname{coker}(\varphi)$ and show that the restriction of $q\colon \widetilde{X}_\varphi \to X$ to each component of $\widetilde{X}_\varphi$ is the covering corresponding to $\ker(\varphi)$.

Exercise 61.17. Let X be a topological space and let $x_0 \in X$. We say that a covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ is *universal* if given any other covering $q\colon (Y, y_0) \to (X, x_0)$ (we do not demand that Y is path-connected) there exists a map $r\colon (\widetilde{X}, \widetilde{x}_0) \to (Y, y_0)$ such that the following diagram commutes:

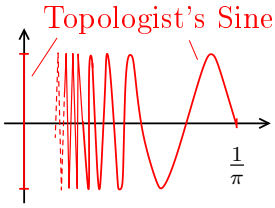
Show that if X is path-connected, locally path-connected and semi-locally simply connected, then a covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ is universal in the above sense if and only if $\widetilde{X}$ is simply connected.

Remark 1. This exercise shows that the above definition of a universal covering is compatible with the definition on page 1372.

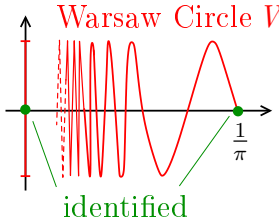
Remark 2. In Exercise 61.18 we will see that in general a simply connected covering is not a universal covering in the above sense.

Exercise 61.18. On page 164 we introduced the Topologist's Sine Curve

$$S \;:=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2.$$



As on page 276 we refer to quotient space $W := S/(0,0)\sim(\frac{1}{\pi},0)$ as the *Warsaw Circle*.



(a) Show that the Warsaw Circle is path-connected and simply connected.
Remark. This exercise is similar to Exercise 2.48 where we showed that the Topologist's Sine Curve S is connected but not path-connected.

(b) Show that the Warsaw Circle is not locally path-connected.

(c) We set $w_0 = [(0,0)]$. Provide an example of a 2-fold covering $q\colon (Y, y_0) \to (W, w_0)$.

Remark. By (a) we know that (W, w_0) is simply connected. The example in (c) shows that the identity map $(W, w_0) \to (W, w_0)$ does not have the universal property stated in Exercise 61.17 respectively Corollary 61.11, even though (W, w_0) is simply connected.

Exercise 61.19. We define the *Modified Warsaw Circle* to be the topological space

$$C \;:=\; X/(0,0)\sim(\tfrac{1}{\pi},0) \qquad \text{where } S \;:=\; \{(0,0)\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2.$$

As in Exercise 5.30 and 61.18 one can show that C is compact and simply connected.

(a) We define the *Topologist's Electrocardiogram* to be the topological space

$$E \;:=\; (S \times \mathbb{Z})/((\tfrac{1}{\pi}, 0), k) \sim ((0,0), k+1) \quad \text{for } k \in \mathbb{Z}.$$

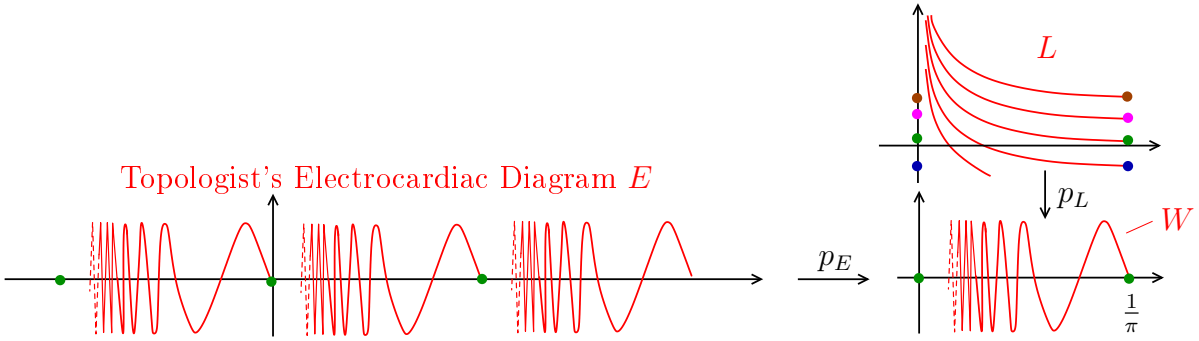
Show that the map

$$\begin{array}{rcl} p_E \colon E & \to & C \\ [(P,k)] & \mapsto & [P] \end{array}$$

is a covering.

(b) We consider the following subspace of $\mathbb{R}^2$:

$$L \;:=\; \Big(0 \times \mathbb{Z} \;\sqcup\; \bigcup_{k \in \mathbb{Z}} \{(x, \tfrac{1}{x} + k) \,|\, x \in (0, \tfrac{1}{\pi}]\}\Big) \setminus (0,k) \sim (\tfrac{1}{\pi}, k) \text{ for } k \in \mathbb{Z}.$$



Show that the map

$$\begin{array}{rcl} p_L \colon L & \to & C \\ [(x,y)] & \mapsto & \begin{cases} [(0,0)], & \text{if } (x,y) \in \{0\} \times \mathbb{Z}, \\ [(x, \sin(\frac{1}{x}))], & \text{if } x > 0. \end{cases} \end{array}$$

is a covering. This covering is called the *Löhlein covering*.

(c) Show that there is no map $f \colon E \to L$ such that $p_L \circ f = p_E$.

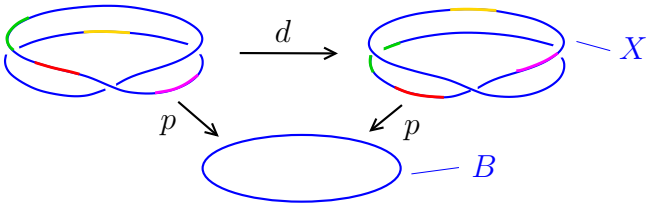
Remark. This shows that the covering $p \colon E \to C$ is not a universal covering in any sense.

62. The deck transformation group

The following definition introduces the main actor of this chapter.

Definition. Let $p\colon X \to B$ be a covering.

(1) A deck transformation is a homeomorphism $d\colon X \to X$ such that $p(d(x)) = p(x)$ for all $x \in X$, i.e. such that the following diagram commutes:



$$\begin{array}{ccc} X & \xrightarrow[\cong]{d} & X \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle p} & \\ & B. & \end{array}$$

The group of deck transformations[730] is called the deck transformation group of the covering $p\colon X \to B$ and we denote it by $\mathrm{Deck}(p\colon X \to B)$.

(2) We say that the covering is regular if for every $b \in B$ the deck transformation group $\mathrm{Deck}(p\colon X \to B)$ acts transitively on $p^{-1}(b)$, i.e. if given any two points x, x' with $p(x) = p(x') = b$ there exists a deck transformation d with $d(x) = x'$. Otherwise we say that the covering is irregular.

For completeness' sake we also mention the following definition even though we will barely make use of it:

(3) Let P be a property of isomorphism types of groups, e.g. cyclic, free, nilpotent, solvable etc. We say the covering $p\colon X \to B$ is a P-covering if the covering is regular and if the deck transformation group has the property P.

Example.

(1) We consider the covering

$$\begin{array}{rccc} p\colon & S^1 & \to & S^1 \\ & z & \mapsto & z^2. \end{array}$$

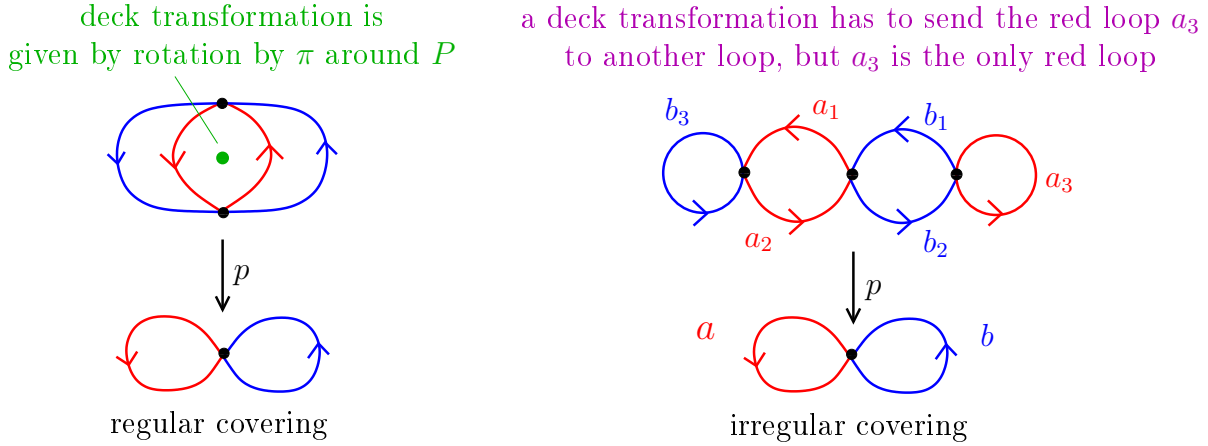
The map $d\colon S^1 \to S^1$ given by $d(z) := -z$ is a deck transformation. It is now clear that the covering is regular.

(2) Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. We define

$$\begin{array}{rccc} f\colon & \widetilde{X} & \to & \widetilde{X} \\ & Q & \mapsto & \text{the unique other point in } p^{-1}(p(Q)). \end{array}$$

In Lemma 48.4 we saw that f is a deck transformation. It follows immediately that any 2-fold covering is regular.

[730] Why do deck transformations form a group?



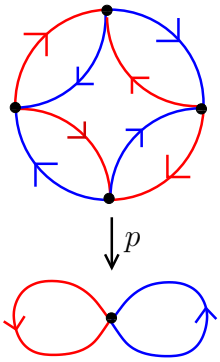
(3) As an important special case of (2) consider a non-orientable path-connected smooth manifold M. We consider the orientation covering

$$\begin{array}{rcl} \widetilde{M} := \{(Q,O) \mid Q \in M \text{ and } O \text{ an orientation of } \mathrm{T}_Q M\} & \to & M \\ (Q,O) & \mapsto & Q \end{array}$$

from page 1109. It is straightforward to show that the map $d\colon \widetilde{M} \to \widetilde{M}$ given by $d((Q,O)) := (Q,-O)$ is a deck transformation of p.

(4) We consider again the first two coverings of topological graphs from the figure on page 1071 which are also shown again in the figure below. The covering maps are the ones suggested by the colors and the directions. We first make the following observations. A deck transformation d does the following:
   (a) it sends a vertex again to a vertex,
   (b) it sends a blue edge to a blue edge, preserving the orientation,
   (c) it sends a red edge to a red edge, preserving the orientation,
   (d) if e is an edge with endpoints P and Q, then $d(e)$ is an edge with endpoints $d(P)$ and $d(Q)$, in particular if e is a loop, then $d(e)$ is also a loop.

   Now we consider the two examples.
   (a) The example on the left admits one non-trivial deck transformation, namely the map that is given by "rotation by π" around the center of the topological graph. The covering is now easily seen to be regular.
   (b) The loop a_3 in the topological graph on the right is the only red loop, so any deck transformation has to send it to itself. It follows that there can be no deck transformation that sends the vertex to the right to any of the other vertices.[731] Thus the covering on the right is irregular.



regular covering irregular covering

(5) Finally we consider the 4-fold coverings illustrated in the figure below. They are both regular coverings. For the topological graph on the left the deck transformation group is isomorphic to $\mathbb{Z}_4$, a generator is given by "rotation by $\frac{\pi}{2}$". The deck transformation group on the right is isomorphic to $\mathbb{Z}_2 \oplus \mathbb{Z}_2$, here one $\mathbb{Z}_2$ summand is given by "rotation by π" and the other one corresponds to "swapping the inner and the outer circle".

[731] Does this covering admit any deck transformation?

deck transformation group $\mathbb{Z}_4$

deck transformation group $\mathbb{Z}_2 \oplus \mathbb{Z}_2$

Lemma 62.1. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces. The deck group $\mathrm{Deck}(p\colon X \to B)$ acts discretely and continuously on X.

Proof. By definition of a deck transformation the action is continuous. We will show in Exercise 62.1 that the action is discrete. ■

Lemma 62.2. (Deck Group-Free Action Lemma) Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces and let d_1 and d_2 be two deck transformations of p. Then the following holds

$$d_1 = d_2 \iff d_1(x_0) = d_2(x_0).$$

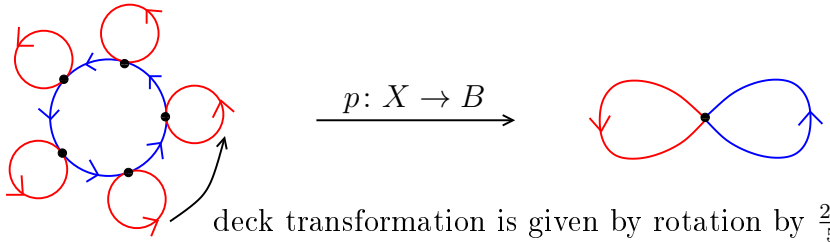
In other words, given any $b_0 \in B$ the deck transformation group $\mathrm{Deck}(p\colon X \to B)$ acts freely on $p^{-1}(b_0)$.

Proof. Evidently we only need to show the "$\Leftarrow$"-direction. Thus let d be a deck transformation of p. One way of stating that d is a deck transformation is to state that the following diagram commutes:

$$\begin{array}{ccc} & & (X, d(x_0)) \\ & \overset{d}{\nearrow} & \downarrow p \\ (X, x_0) & \xrightarrow[p]{} & (B, b_0). \end{array}$$

Put differently, the map d can be viewed as a lift of the map $(X, x_0) \to (B, b_0)$ to the covering $(X, d(x_0)) \to (B, b_0)$. By the uniqueness of lifts[732], that we showed in the Map Lifting Criterion 61.2 (2), we now see that two deck transformations d_1 and d_2 of p with $d_1(x_0) = d_2(x_0)$ agree. ■

Example. We let $B = (S^1 \times \{a\} \sqcup S^1 \times \{b\})/(1, a) \sim (1, b)$, i.e. B is the wedge of two circles and we consider



$$X = (S^1 \sqcup (S^1 \times \mathbb{Z}_5))/(\exp(2\pi \mathrm{i} n/5) \sim (1, n)) \text{ for } n \in \mathbb{Z}_5,$$

i.e. X is a circle with five circles attached at the points $\exp(2\pi \mathrm{i} k/5)$, $k = 0, \ldots, 4$. Then the map

$$p\colon (S^1 \sqcup (S^1 \times \mathbb{Z}_5))/\sim \to \ G = (S^1 \times \{a\} \sqcup S^1 \times \{b\})/(1, a) \sim (1, b)$$

[732] Here we use that X is path-connected.

that is given by $p(z) = (z^5, a)$ for $z \in S^1$ and $p((z,n)) = (z,b)$ for $(z,n) \in S^1 \times \mathbb{Z}_5$, is a covering map of degree five.

We consider the map

$$\begin{array}{rcl} \mathbb{Z}_5 & \to & \mathrm{Deck}(p\colon X \to B) \\ m & \mapsto & \left(\begin{array}{rcll} X & \to & X & \\ z & \mapsto & \exp(2\pi \mathrm{i} m/5) \cdot z, & \text{for } z \in S^1, \\ (z,n) & \mapsto & (z, m+n) & \text{for } (z,n) \in S^1 \times \mathbb{Z}_5 \end{array} \right) \end{array}$$

In the figure above this corresponds to "rotation of X by the angle $\frac{2\pi m}{5}$". It is straightforward to show that this map is well-defined, i.e. the maps on the right are deck transformations, and using the Deck Group-Free Action Lemma 62.2 one can easily see that this map is an isomorphism. Also one can now convince oneself easily that the covering $p\colon X \to B$ is regular.

Lemma 62.3. Let X be a path-connected topological space on which a group G acts continuously and discretely. We consider the corresponding covering $p\colon X \to X/G$. Then $p\colon X \to X/G$ is regular and the map

$$\begin{array}{rcl} \Phi\colon G & \to & \mathrm{Deck}(p\colon X \to X/G) \\ g & \mapsto & \begin{pmatrix} X & \to & X \\ x & \mapsto & g \cdot x \end{pmatrix} \end{array}$$

is an isomorphism of groups.

Proof. It is straightforward to see that the maps $x \mapsto gx$ are indeed deck transformations. It follows almost immediately that the covering $p\colon X \to X/G$ is regular. Also it follows easily from the axioms of a group action that Φ is a homomorphism of groups. Furthermore it is clear that Φ is a monomorphism.

It remains to show that Φ is an epimorphism. So let $d \in \mathrm{Deck}(p\colon X \to X/G)$ be a deck transformation. We pick $x \in X$. Since $p(d(x)) = p(x)$ we have $d(x) = gx$ for some $g \in G$. Since X is path-connected it follows from the Deck Group-Free Action Lemma 62.2 that $d(y) = gy$ for all $y \in X$. This shows that Φ is an epimorphism. ■

Lemma 62.4. Any 2-fold covering of path-connected topological spaces is regular and the deck transformation group contains precisely two elements.

Proof. Let $p\colon X \to B$ be a 2-fold covering of path-connected topological spaces. By Lemma 48.4 we know that

$$\begin{array}{rcl} d\colon X & \to & X \\ x & \mapsto & \text{the unique other element of } p^{-1}(p(x)) \end{array}$$

is a deck transformation. Evidently it is regular. It follows easily from the Deck Group-Free Action Lemma 62.2 and our hypothesis that X, B are path-connected that any deck transformation of p is either the identity or it equals the above deck transformation d. ■

We recall the following important, albeit somewhat technical, definition.

Definition. Let G be a group and let $H \subset G$ be a subgroup. The normalizer $N(H)$ of the subgroup $H \subset G$ is defined as

$$N(H) \ := \ \{g \in G \mid g^{-1}Hg = H\}.$$

The following lemma summarizes a few elementary properties of the normalizer of a subgroup.

Lemma 62.5. Let G be a group and let $H \subset G$ be a subgroup.

(1) The subgroup H of G is normal if and only if $N(H) = G$.
(2) The normalizer $N(H)$ of $H \subset G$ is a subgroup of G.
(3) The normalizer $N(H)$ of $H \subset G$ is the largest subgroup of G which contains H as a normal subgroup, in the sense that if A is a subgroup of G which contains H as a normal subgroup, then $A \subset N(H)$.

Proof. Both statements are easily verified. Alternatively see [**Isa1994**, p. 26] for the elementary proof. ■

We return to topology and we consider one more example in detail.

Example. Let Y be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $y_0 \in Y$. Furthermore let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup. By the Covering Existence Theorem 61.5 there exists a path-connected covering $p\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$. We recall the construction of X. We first considered

$$P \ := \ \{\text{all paths in } Y \text{ with starting point } y_0\}$$

and for $u, v \in W$ we wrote

$$u \sim v \quad :\Leftrightarrow \quad u \text{ and } v \text{ have the same endpoint and } [u * \overline{v}] \in \Gamma.$$

We defined $X = P/\sim$ and the projection $p\colon P/\sim \to Y$ that is given by $[w] \mapsto w(1)$. We then showed that, with an appropriate topology on $P/\sim$, the map $p\colon P/\sim \to Y$ is a path-connected covering with $p_*(\pi_1(P/\sim, x_0)) = \Gamma$.

As in the proof of Proposition 61.14 we now would like to construct deck transformations by precomposing elements in P by a loop in y_0. More precisely, let g be a loop in (Y, y_0). We consider the map

$$\begin{array}{ccc} P & \to & P \\ w & \mapsto & g * w \end{array}$$

We need to check that the map respects our equivalence relation $\sim$ on P. So suppose that $u, v \in P$ are equivalent. Then $g * u$ and $g * v$ still have the same endpoint. Now we need to consider the second condition. We have

$$[(g * u) * (\overline{g * v})] \ = \ [g * u * \overline{v} * \overline{g}] \ = \ [g] * \underbrace{[u * \overline{v}]}_{\in \Gamma} * [g]^{-1}.$$

In general it is not the case that the right-hand side lies again in Γ. But it is true if $[g]$ lies in the normalizer of Γ. As in the proof of Proposition 61.14 it is now straightforward to see that the map

$$\begin{array}{rcl} \Psi\colon N(\Gamma)/\Gamma & \to & \mathrm{Deck}(p\colon X \to Y) \\ [g] & \mapsto & \begin{pmatrix} P/\!\sim & \to & P/\!\sim \\ [u] & \mapsto & [g*u] \end{pmatrix} \end{array}$$

is a well-defined homomorphism. We will see in Proposition 62.6 that this in fact an isomorphism of groups.

Now we want to consider the general case of a covering. So let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B,b_0)$ and $\Gamma := p_*(\pi_1(X,x_0))$.[733] Now the question arises whether there is a connection between the groups π, Γ and $\mathrm{Deck}(p\colon X \to B)$.

Definition. Similar to the proof of the Fundamental Group-via-Actions Theorem 48.16 we can consider the following map[734]

$$\begin{array}{rcl} \Xi_{(X,x_0)}\colon \mathrm{Deck}(p\colon X \to B) & \to & \pi/\Gamma \\ d & \mapsto & \big[p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))\big]. \end{array}$$

It is straightforward to see that this map is well-defined, i.e. it does not depend on the choice of the path.

The question now arises, whether this map Φ is a group isomorphism. But in general this is not the case, after all, if Γ is not normal in π, then π/Γ is not even a group. But we have the following proposition:

Proposition 62.6. Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces. We suppose that X and B are both path-connected and locally path-connected. We write $\pi := \pi_1(B,b_0)$ and $\Gamma := p_*(\pi_1(X,x_0))$. The above map

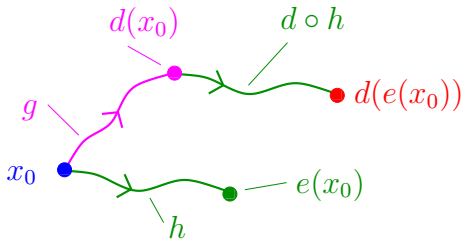
$$\begin{array}{rcl} \Xi_{(X,x_0)}\colon \mathrm{Deck}(p\colon X \to B) & \to & \pi/\Gamma \\ d & \mapsto & \big[p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))\big]. \end{array}$$

restricts to an isomorphism of groups

$$\Xi_{(X,x_0)}\colon \mathrm{Deck}(p\colon X \to B) \xrightarrow{\cong} N(\Gamma)/\Gamma.$$

Proof. Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B,b_0)$, $\Gamma := p_*(\pi_1(X,x_0))$, $D := \mathrm{Deck}(p\colon X \to B)$ and $\Phi := \Xi_{(X,x_0)}$.

(A) First we have to show that $\Phi(D)$ lies indeed in $N(\Gamma)/\Gamma$. Thus let $d \in D$. We need to show that $\Phi(d)$ lies in $N(\Gamma)/\Gamma$. Thus let f be a loop in (X,x_0) and and let g be a path in X from x_0 to $d(x_0)$. We have to verify that $[\overline{p\circ f}]\cdot[p\circ g]\cdot[p\circ f] \in \Gamma$. Indeed the following holds



$$[\overline{p\circ f}]\cdot[p\circ g]\cdot[p\circ f] \;=\; \big[\overline{p\circ f} * p\circ g * p\circ f\big] \;=\; \big[p\circ \big(\underbrace{\overline{f} * g * f}_{\text{loop in } (X,x_0)}\big)\big] \;\in\; p_*(\pi_1(X,x_0)) = \Gamma.$$

[733] Recall that by Corollary 48.14 the induced map $p_*\colon \Gamma \to \pi$ is injective, thus $\Gamma \cong \pi_1(X,x_0)$.

[734] We denote hereby with $[p\circ f]$ not only the equivalence class of the loop $p\circ f$ in π, but also its equivalence class π/Γ, since the notation $[p\circ f]\Gamma$ is too cumbersome.

(B) Now we have to show that Φ is a group homomorphism. So let d and e be two deck transformations. We pick a path g from x_0 to $d(x_0)$ and we pick a path h from x_0 to $e(x_0)$. Then

$$\Phi(d)\cdot\Phi(e) \underset{\text{definition of } \Phi(e) \text{ and } \Phi(d)}{=} [p\circ g]\cdot[p\circ h] \underset{\text{since } p\circ d = p}{=} [p\circ g]\cdot[p\circ(d\circ h)] \overset{\text{endpoint of } g \text{ equals starting point of } d\circ h}{=} [g*(d\circ h)] \underset{\substack{\text{since } g*(d\circ h) \text{ is a path} \\ \text{from } x_0 \text{ to } d(e(x_0)), \text{ see the figure below}}}{=} \Phi(e\circ d).$$

(C) Now we will construct a map $\Psi\colon N(\Gamma)/\Gamma \to D$ in the inverse direction. Thus let $[f]\in N(\Gamma)\subset\pi=\pi_1(B,b_0)$ where f is a loop in (B,b_0). Let x_1 be the endpoint of the lift $\widetilde{f}$ of f to the starting point x_0.[735] We have $p(x_1)=p\big(\widetilde{f}(1)\big)=f(1)=x_0$. Thus we obtain the following diagram of maps of pointed topological spaces:

$$\begin{array}{ccc} & & (X,x_1) \\ & & \big\downarrow p \\ (X,x_0) & \xrightarrow{\ p\ } & (B,b_0). \end{array}$$

Then

$$p_*(\pi_1(X,x_1)) \underset{\text{by Proposition 47.10 since } \widetilde{f} \text{ is a path from } x_0 \text{ to } x_1}{=} \big\{\big[p\circ\big(\overline{\widetilde{f}}*g*\widetilde{f}\big)\big]\,\big|\,[g]\in\pi_1(X,x_0)\big\} \underset{\text{since } [f]\in N(\Gamma)}{\substack{=\ [f]\,p_*(\pi_1(X,x_0))\,[f]^{-1} \\ =\ p_*(\pi_1(X,x_0)).}}$$

Note that it follows from the Map Lifting Criterion 61.2 that there exists a lift $\widetilde{p}\colon(X,x_0)\to(X,x_1)$ of p, i.e. there exists a map $\widetilde{p}$ such that the following diagram commutes:

$$\begin{array}{ccc} & & (X,x_1) \\ & \overset{\widetilde{p}}{\nearrow} & \big\downarrow p \\ (X,x_0) & \xrightarrow{\ p\ } & (B,b_0). \end{array}$$

The map is $\widetilde{p}$ is now by definition a deck transformation.

We have thus constructed a map $N(\Gamma)\to D$. We still need to show that this map descends to a map $N(\Gamma)/\Gamma\to D$. So let $[f]\in N(\Gamma)$ and let $[g]\in\Gamma$. We denote by $\widetilde{f}$ the lift of f to the starting point x_0. Similarly we define $\widetilde{g*f}$. By the above we only

[735] According to Corollary 48.13 the definition of x_1 does not depend on the choice of the representative of $[f]\in N(\Gamma)$.

need to show that the endpoints of $\widetilde{f}$ and $\widetilde{g * f}$ agree. In fact we have

$$\widetilde{g * f}(1) \underset{\text{Lemma 61.3}}{=} \begin{array}{c}\text{endpoint of the lift of } f\\ \text{to the starting point } \widetilde{g}(1)\end{array} \underset{\text{by Lemma 48.15 (2) (1) since } [g] \in p_*(\pi_1(X,x_0))}{=} \begin{array}{c}\text{endpoint of the lift of } f\\ \text{to the starting point } x_0\end{array} = \widetilde{f}(1)$$

(D) Now we want to show that Φ is a bijection. It suffices to show that $\Psi \circ \Phi = \mathrm{id}$ and $\Phi \circ \Psi = \mathrm{id}$.

First let $d \in D$. Then

$$\begin{aligned}\Psi(\Phi(d)) &= \Psi(\text{loop } f \text{ in } (B,b_0) \text{ that lifts to a path from } x_0 \text{ to } d(x_0))\\ &= \text{deck transformation that sends } x_0 \text{ to } d(x_0) \underset{\text{Deck Group-Free Action Lemma 62.2}}{=} d\end{aligned}$$

This shows that $\Psi \circ \Phi$ is the identity.

Now let $g \in N(\Gamma)/\Gamma$. We pick a representative loop s in b_0 and we denote by $\widetilde{s}$ the lift of s to the starting point x_0. We denote by x_1 the endpoint of $\widetilde{s}$. Then

$$\Phi(\Psi(g)) = \Big[p \circ \big(\text{path in } X \text{ from } x_0 \text{ to } \overbrace{\Psi(g)(x_0)}^{=x_1}\big)\Big] \underset{\widetilde{s} \text{ is a path from } x_0 \text{ to } x_1}{=} \big[p \circ \widetilde{s}\big] = [s] = g.$$

This shows that $\Phi \circ \Psi$ is the identity. ∎

Remark. Let X be a path-connected topological space on which a group G acts continuously and discretely. We denote by $p\colon X \to X/G$ the natural projection . Finally let $x_0 \in X$. We now have three isomorphisms relating the groups G, $\mathrm{Deck}(p\colon X \to X/G)$ and $\pi_1(X/G,[x_0])$. More precisely we consider the isomorphisms

$$\begin{array}{rcl}\Psi\colon G &\to& \mathrm{Deck}(p\colon X \to X/G)\\ g &\mapsto& \begin{pmatrix} X & \to & X\\ x & \mapsto & g \cdot x_0\end{pmatrix}\end{array} \quad \text{and} \quad \begin{array}{rcl}\Theta\colon G &\to& \pi_1(X/G,[x])\\ g &\mapsto& [p \circ (\text{path in } X \text{ from } x_0 \text{ to } g \cdot x_0)]\end{array}$$

from Lemma 62.3 and the Fundamental Group-via-Actions Theorem 48.16. Furthermore we consider isomorphism

$$\begin{array}{rcl}\Xi_{(X,x_0)}\colon \mathrm{Deck}(p\colon X \to B) &\to& \pi_1(X,x_0)\\ d &\mapsto& \big[p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))\big]\end{array}$$

from Proposition 62.6. Fortunately these three isomorphisms are compatible in the sense that $\Xi_{(X,x_0)} \circ \Psi = \Theta$.

Proof. This lemma follows immediately from the definitions. ∎

In most applications we will use the following special case of Proposition 62.6.

Proposition 62.7. Let (X,x_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let $\gamma\colon \pi_1(X,x_0) \to G$ be an epimorphism onto a group G. We denote by $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ the covering corresponding to $\ker(\gamma)$ that is given by the Covering Existence Theorem 61.5 and that is unique up to covering equivalence by the Covering Uniqueness Theorem 61.9. Then the

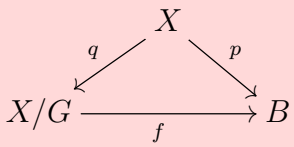
map

$$\begin{array}{rccccc} \Phi\colon \mathrm{Deck}(p\colon \widetilde{X} \to X) & \to & \pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0)) & \xrightarrow{\gamma} & G. \\ d & \mapsto & \big[p \circ (\text{path from } x_0 \text{ to } d(x_0))\big] & & \end{array}$$

is an isomorphism.

Proof. First note that $p_*(\pi_1(\widetilde{X},\widetilde{x}_0)) = \ker(\gamma)$ is a normal subgroup of $\pi_1(X,x_0)$. Therefore the normalizer of $\Gamma := p_*(\pi_1(\widetilde{X},\widetilde{x}_0))$ equals $\pi_1(X,x_0)$. It now follows immediately from Proposition 62.6 that the homomorphism on the left is an isomorphism. The homomorphism on the right is an isomorphism since $p_*(\pi_1(\widetilde{X},\widetilde{x}_0)) = \ker(\gamma)$. ■

Convention. Let (X,x_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected.



(1) Let $\gamma\colon \pi_1(X,x_0) \to G$ be an epimorphism onto some group G. Furthermore let $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ be a covering corresponding to $\ker(\gamma)$. We use the inverse of the isomorphism $\mathrm{Deck}(p\colon \widetilde{X} \to X) \xrightarrow{\cong} G$ from Proposition 62.7 to equip $\widetilde{X}$ with a left G-action.

(2) Let $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ be a universal covering. We use the inverse of the isomorphism $\mathrm{Deck}(p\colon \widetilde{X} \to X) \xrightarrow{\cong} \pi_1(X,x_0)$ from Proposition 62.6 to equip $\widetilde{X}$ with a left $\pi_1(X,x_0)$-action.

The following corollary to Proposition 62.6 gives a complete characterization of regular coverings.

Corollary 62.8. (Regular Covering-Characterization Corollary) Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces that are path-connected and locally path-connected. Then the following statements are equivalent:[736]

(1) The covering is regular.
(2) The deck transformation group $\mathrm{Deck}(p\colon X \to B)$ acts transitively on $p^{-1}(b_0) \subset X$.[737]
(3) The subgroup $p_*(\pi_1(X,x_0))$ is a normal subgroup of $\pi_1(B,b_0)$.
(4) There exists a group G which acts discretely on X and there exists a homeomorphism $f\colon X/G \to B$ such that the following diagram commutes:

where $q\colon X \to X/G$ is the natural projection .

If p is a finite covering then the above statements are furthermore equivalent to

(5) $\#\,\mathrm{Deck}(p\colon X \to B) = [X:B]$.

Remark. Let $p\colon (X,x_0) \to (B,b_0)$ be a 2-fold covering of path-connected pointed topological spaces. In Lemma 62.4 we saw that p is regular, which by the Regular Covering-Characterization Corollary 62.8 means that the index two subgroup $p_*(\pi_1(X,x_0))$ of $\pi_1(B,b_0)$

[736] Note that being regular does not depend on the choice of $b_0 \in B$. Thus, by the equivalence of the statements, we see that if Statements (2) and (3) hold for a single b_0, they hold for any point in B.
[737] Note that by the Deck Group-Free Action Lemma 62.2 we already know that the deck transformation group acts freely on $p^{-1}(b_0)$.

is normal. In fact we already showed in Lemma 49.6 that any index 2 subgroup Γ of a group π is normal.

Proof. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B, b_0)$, $\Gamma := p_*(\pi_1(X, x_0))$ and $D = \mathrm{Deck}(p\colon X \to B)$. The following four steps prove the equivalence of (1), (2) (3) and (4).

(1) $\Leftrightarrow$ (2) Recall that a covering is regular if for every $b \in B$ the group D acts transitively on $p^{-1}(b)$. Thus (1) $\Rightarrow$ (2) is trivial. Now suppose that d acts transitively on $p^{-1}(b_0)$. Let b be some other point in B. Since B is path-connected there exists a path s from b to b_0.

Now let x, x' be two points in $p^{-1}(b)$. We denote by $\widetilde{s}$ the lift of s to the starting point x and similarly we define $\widetilde{s}'$. We denote by x_0 and x_0' the endpoints of $\widetilde{s}$ and $\widetilde{s}'$. Since D acts transitively on $p^{-1}(b_0)$ there exists a deck transformation d with $d(x_0) = x_0'$. By the uniqueness of lifts to a starting point we then also have $d \circ \widetilde{s} = \widetilde{s}'$. But then we also have that d turns the starting point of $\widetilde{s}$ into the starting point of $\widetilde{s}'$, i.e. we have $d(x) = x'$.

(2) $\Leftrightarrow$ (3) We consider again the map

$$\begin{aligned} \Phi\colon \mathrm{Deck}(p\colon X \to B) &\mapsto \pi/\Gamma \\ d &\mapsto \big[p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))\big]. \end{aligned}$$

We first prove the following claim.

Claim. We have the following equivalence of statements:

$$D \text{ acts transitively on } p^{-1}(b_0) \subset X \quad \Leftrightarrow \quad \Phi\colon D \to \pi/\Gamma \text{ is surjective.}$$

Proof. First suppose that D acts transitively on $p^{-1}(b_0) \subset X$. Let $g \in \pi/\Gamma$ and pick a loop f that represents g. We denote by $\widetilde{f}$ the unique lift of f to the starting point x_0 and we denote by $\widetilde{x}_0$ the endpoint of $\widetilde{f}$. Since D acts transitively there exists a deck transformation d with $d(x_0) = \widetilde{x}_0$. Now

$$\Phi(d) = [p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))] \underset{\substack{\uparrow \\ \text{since } \widetilde{f} \text{ is a path from } x_0 \text{ to } d(x_0)}}{=} [p \circ (d \circ \widetilde{f})] \underset{\substack{\uparrow \\ \text{since } p \circ d = p}}{=} [p \circ \widetilde{f}] = [f] = g.$$

Now suppose that $\Phi\colon D \to \pi/\Gamma$ is surjective. Let $\widetilde{x}_0 \in p^{-1}(b_0)$. We pick a path $\widetilde{f}$ from x_0 to $\widetilde{x}_0$ and we denote by f the loop $p \circ \widetilde{f}$. Since Φ is surjective there exists a deck transformation d with $\Phi(d) = [f]$. But then $d(x_0) = \widetilde{x}_0$. ⊞

Now we have the following equivalences

$$\begin{aligned} D \text{ acts transitively on } p^{-1}(b_0) \subset X &\iff \Phi\colon D \to \pi/\Gamma \text{ is surjective} \\ &\underset{\substack{\uparrow \\ \text{Proposition 62.6}}}{\iff} \pi = N(\Gamma) \underset{\substack{\uparrow \\ \text{by the definitions}}}{\iff} \Gamma \text{ is normal in } \pi. \end{aligned}$$

(1) $\Rightarrow$ (4) We will show that the deck transformation group D has the desired properties.

We first show that the deck transformation group acts discretely on X. So let $x \in X$. We write $b = p(x)$. Since $p\colon X \to B$ is a covering there exists a connected open neighborhood U of b that is uniformly covered. This means that the restriction of p to each component of $p^{-1}(U)$ is a homeomorphism. Now

let V be the component of $p^{-1}(U)$ that contains x. Then $gV \cap V = \varnothing$ for each non-trivial g. This shows that the action of D is discrete.

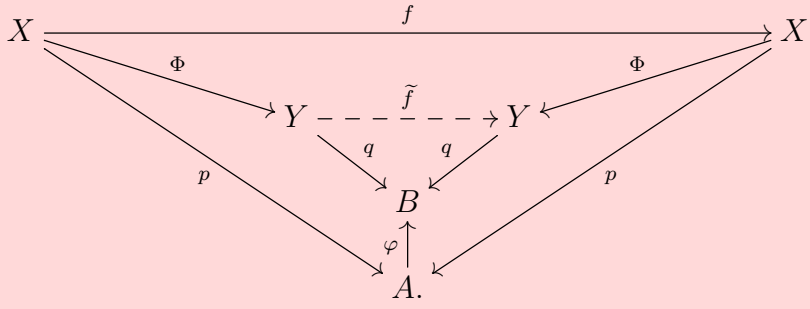
The map $p\colon X \to B$ has the property that $p(gx) = p(x)$ for all $g \in D$. Therefore the map p factors through a map $f\colon X/D \to B$. The map f is clearly surjective. Furthermore it is injective since we suppose that D acts transitively on each $p^{-1}(b)$. Finally the map f is not only continuous but, as follows easily from Lemma 48.3 (1), it is also open. Thus f is a homeomorphism.

(4) $\Rightarrow$ (1) Now suppose that such a homeomorphism $f\colon X/G \to B$ exists. First note that for each $g \in G$ the map $x \mapsto gx$ not only defines a deck transformation of the covering $q\colon X \to X/G$ but also of the covering $p\colon X \to B$. Now let $b \in B$ and let $x, x' \in X$ with $p(x) = p(x')$. Since f is a homeomorphism we also have $q(x) = q(x')$. Hence there exists a $g \in G$ with $gx = x'$.

Now we suppose that p is a finite covering. We show the following equivalence:

(5) $\Leftrightarrow$ (3) We have the following equivalences:[738]

$$\begin{array}{ccccc} & \overset{\text{Lemma 48.15 (3)}}{\downarrow} & & \overset{\text{Proposition 62.6}}{\downarrow} & \\ \#D = [X : B] & \Longleftrightarrow & \#D = [\pi : \Gamma] & \Longleftrightarrow & [N(\Gamma) : \Gamma] = [\pi : \Gamma] \\ & \Longleftrightarrow & N(\Gamma) = \pi & \Longleftrightarrow & \Gamma \subset \pi \text{ is a normal subgroup.} \end{array}$$



■

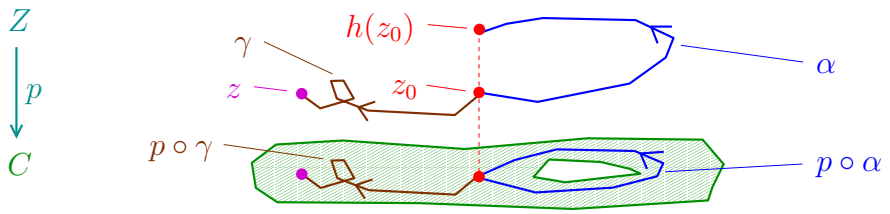
Proposition 62.9. (Induced-Deck Transformation Proposition) Let X, Y, A and B be topological spaces that are path-connected and locally path-connected. Furthermore let $p\colon X \to A$ be a covering and let $q\colon Y \to B$ be a *regular* covering. Finally let $\varphi\colon A \to B$ and let $\Phi\colon X \to Y$ be maps such that the following diagram commutes:

$$\begin{array}{ccc} X & \xrightarrow{\Phi} & Y \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ A & \xrightarrow{\varphi} & B. \end{array}$$

In this setting the following two statements hold:

(1) Given any $f \in \mathrm{Deck}(p\colon X \to B)$ there exists a unique $\widetilde{f} \in \mathrm{Deck}(q\colon Y \to B)$ such that the following diagram commutes:

(2) The map $f \mapsto \widetilde{f}$ from (1) defines a group homomorphism



$$\mathrm{Deck}(p\colon X \to A) \;\to\; \mathrm{Deck}(q\colon Y \to B).$$

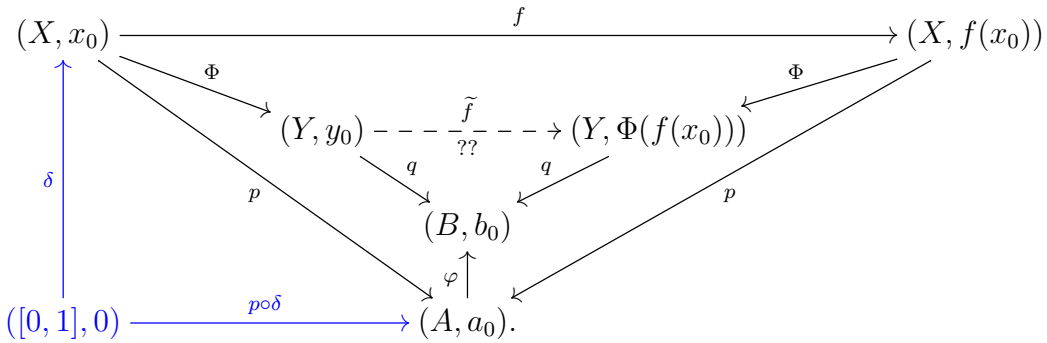
[738] Where do we actually use in the argument that the covering is finite?

In the proof of the Induced-Deck Transformation Proposition 62.9 we will use the following lemma which gives a sometimes useful description of a deck transformation.

Lemma 62.10. Let $r\colon (Z, z_0) \to (C, c_0)$ be a covering and let $h\colon Z \to Z$ be a deck transformation. Let $z \in Z$. We pick a path $\alpha\colon [0,1] \to Z$ from z_0 to $h(z_0)$ and we pick a path $\gamma\colon [0,1] \to Z$ from z_0 to z. Then

$h(z)$ = endpoint of the unique lift of $(p \circ \alpha) * (p \circ \gamma)\colon [0,1] \to C$ to the starting point z_0.

Proof of Lemma 62.10. Note that



endpoint of the unique lift of $(p \circ \alpha) * (p \circ \gamma)\colon [0,1] \to C$ to the starting point z_0
$= \uparrow$ endpoint of $\alpha * h \circ \gamma = (h \circ \gamma)(1) = h(\gamma(1)) = h(z)$.

since h is a deck transformation we see that $h \circ \gamma$ is the lift of $p \circ \gamma$ to starting point $\alpha(1) = h(z_0)$

■

Proof of the Induced-Deck Transformation Proposition 62.9.

(1) We pick $x_0 \in X$. We set $a_0 = p(x_0)$, $y_0 := \Phi(x_0)$ and $b_0 := q(y_0)$. We consider the following diagram of maps between pointed topological spaces:

(The maps in blue will only be explained a little later on.)

Claim 1. We have $q_*(\pi_1(Y, y_0)) = q_*(\pi_1(Y, \Phi(f(x_0))))$.

Proof. Since Y is path-connected we can pick a path $\gamma\colon [0,1] \to Y$ with $\gamma(0) = y_0$ and $\gamma(1) = \Phi(f(x_0))$. Then

$$q_*(\pi_1(Y, y_0)) \underset{\uparrow}{=} \overbrace{[q \circ \gamma]}^{\in \pi_1(B, b_0)} \cdot q_*(\pi_1(Y, \Phi(f(x_0)))) \cdot [q \circ \gamma]^{-1} \underset{\uparrow}{=} q_*(\pi_1(Y, \Phi(f(x_0)))).$$

by the Change-of-Base Point Proposition 47.10

by the Regular Covering-Characterization Corollary 62.8, since $q\colon Y \to B$ is a regular covering

⊞

Since $q_*(\pi_1(Y, y_0)) = q_*(\pi_1(Y, \Phi(f(x_0))))$ and since Y is locally path-connected we obtain from the Map Lifting Criterion 61.2 a unique map $\widetilde{f}\colon (Y, y_0) \to (Y, \Phi(f(x_0)))$

such that $q = q \circ \widetilde{f}$, i.e. such that the small triangle commutes. It remains to prove the following claim.

Claim 2. The quadrilateral on top also commutes.

Proof. Let $x \in X$. We need to show that $(\widetilde{f} \circ \Phi)(x) = (\Phi \circ f)(x)$.

(a) We pick a path $\alpha\colon [0,1] \to X$ from x_0 to $f(x_0)$ and we pick a path $\gamma\colon [0,1] \to X$ from x_0 to x.

(b) Evidently $\Phi \circ \alpha\colon [0,1] \to Y$ is a path from $y_0 = \Phi(x_0)$ to $\Phi(f(x_0))$ and evidently $\Phi \circ \gamma\colon [0,1] \to Y$ is a path from $y_0 = \Phi(x_0)$ to $\Phi(x)$.

(c) Let $\delta\colon [0,1] \to X$ be the unique lift of

$$(p \circ \alpha) * (p \circ \gamma) = p \circ (\alpha * \gamma)\colon [0,1] \to A$$

to the starting point x_0.

(d) Note that

$$q \circ \Phi \circ \delta \underset{\substack{\uparrow \\ \text{since } q \circ \Phi = \varphi \circ p}}{=} \varphi \circ p \circ \delta \underset{\substack{\uparrow \\ \text{since } \delta \text{ lift of } \alpha * \gamma}}{=} \varphi \circ p \circ (\alpha * \gamma) \underset{\substack{\uparrow \\ \text{since } q \circ \Phi = \varphi \circ p}}{=} (q \circ \Phi) \circ (\alpha * \gamma) = q \circ (\Phi \circ \alpha * \Phi \circ \gamma).$$

(e) It follows from (d) that $\Phi \circ \delta$ is the (necessarily unique) lift of $q \circ (\Phi \circ \alpha) * q \circ (\Phi \circ \gamma)$ to the starting point y_0.

In summary we see that

$$\widetilde{f}(\Phi(x)) \underset{\substack{\uparrow \\ \text{by Lemma 62.10 with (b) and (e)}}}{=} (\Phi \circ \delta)(1) = \Phi(\delta(1)) \underset{\substack{\uparrow \\ \text{by Lemma 62.10 and choice of } \delta}}{=} \Phi(f(x)) = (\Phi \circ f)(x).$$

⊞

(2) This statement follows easily from Statement (1). We leave it to the reader to fill in details. ■

Lemma 62.11. Let X, Y, A and B be topological spaces that are path-connected and locally path-connected. Furthermore let $p\colon X \to A$ be a covering and let $q\colon Y \to B$ be a *regular* covering. Finally let $\varphi\colon A \to B$ and let $\Phi\colon X \to Y$ be maps such that the following diagram commutes:

$$\begin{array}{ccc} X & \xrightarrow{\quad\Phi\quad} & Y \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ A & \xrightarrow{\quad\varphi\quad} & B. \end{array}$$

Let $x_0 \in X$. We write $a_0 = p(x_0)$, $y_0 = \Phi(x_0)$ and $b_0 = q(\Phi(x_0))$. In this setting the following diagram commutes:

$$\begin{array}{ccc} \mathrm{Deck}(p\colon X \to A) & \xrightarrow{\quad\Xi_{(X,x_0)}\quad} & \pi_1(A,a_0)/p_*(\pi_1(X,x_0)) \\ \downarrow & & \downarrow{\scriptstyle \varphi_*} \\ \mathrm{Deck}(q\colon Y \to B) & \xrightarrow{\quad\Xi_{(Y,y_0)}\quad} & \pi_1(B,b_0)/q_*(\pi_1(Y,y_0)), \end{array}$$

where the horizontal maps are the maps we introduced on page 1388, where the left vertical map is the map given by the Induced-Deck Transformation Proposition 62.9 and the right vertical map is induced by $\Phi_*\colon \pi_1(A,a_0) \to \pi_1(B,b_0)$.[739]

[739] It follows from $q \circ \Phi = \varphi \circ p$ that $\varphi_*(p_*(\pi_1(X,x_0))) \subset q_*(\pi_1(Y,y_0))$.

Proof. The lemma follows immediately from the definitions. ■

The following proposition tells us how one can obtain in a relatively explicit way "all" coverings from the universal covering. It can be viewed as a refinement of Proposition 61.14.

Proposition 62.12. Let X be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let $x_0 \in X$ and let $p\colon \widetilde{X} \to X$ be a universal covering. We pick $\widetilde{x}_0 \in \widetilde{X}$ with $p(\widetilde{x}) = x_0$. We endow $\widetilde{X}$ with the $\pi_1(X, x_0)$-action that we introduced on page 1391. Let $\Gamma\colon \pi_1(X, x_0)$ be a subgroup. The map

$$\begin{array}{rcl} q\colon \widetilde{X}/\Gamma & \to & X \\ [\widetilde{x}] & \mapsto & p(x) \end{array}$$

is a covering with $q_*(\pi_1(\widetilde{X}/\Gamma, [\widetilde{x}_0])) = \Gamma$.

Proof. By Lemma 62.1 we know that the action of Γ on $\widetilde{X}$ is discrete and continuous. Thus it follows from Proposition 48.10 that the map $q\colon \widetilde{X}/\Gamma \to X$ is indeed a covering. In the Fundamental Group-via-Actions Theorem 48.16 we gave an explicit isomorphism $\pi_1(\widetilde{X}/\Gamma, [\widetilde{x}_0]) \cong \Gamma$. One can easily verify that this map is precisely q_*. ■

The following proposition is a refinement of the Lift-to-Universal Coverings Proposition 61.13.

Proposition 62.13. Let X and Y be topological spaces that are path-connected, locally path-connected and semi-locally simply connected. Let $p\colon \widetilde{X} \to X$ and $q\colon \widetilde{Y} \to Y$ be universal coverings. Furthermore suppose we are given a map $f\colon X \to Y$ and points $x_0 \in X$, $\widetilde{x}_0 \in \widetilde{X}$ and $\widetilde{y}_0 \in \widetilde{Y}$ with $p(\widetilde{y}_0) = f(x_0)$. By the Lift-to-Universal Coverings Proposition 61.13 there exists a unique map $\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}$ with $\widetilde{f}(\widetilde{x}_0) = \widetilde{y}_0$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X} & \overset{\widetilde{f}}{\dashrightarrow} & \widetilde{Y} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{\quad f \quad} & Y. \end{array}$$

We equip $\widetilde{X}$ with the action by $\pi_1(X, x_0)$ and we equip $\widetilde{Y}$ with the action by $\pi_1(Y, y_0)$ that we introduced on page 1391. The map $\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}$ has the following property: given any $\widetilde{x} \in \widetilde{X}$ and given any $g \in \pi_1(X, x_0)$ we have

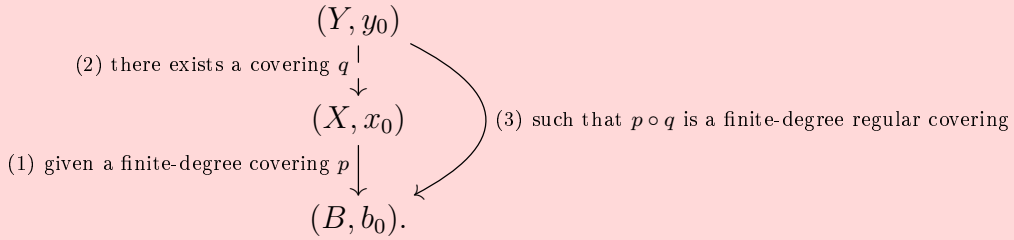
$$\widetilde{f}(g \cdot \widetilde{x}) \;=\; \underbrace{f_*(g)}_{\in \pi_1(Y, y_0)} \cdot \widetilde{f}(\widetilde{x}).$$

Proof. It is worth recalling how the action of fundamental groups on coverings are actually defined. In Proposition 167.1 we saw that if $r\colon (\widehat{Z}, \widehat{z}_0) \to (Z, z_0)$ is a regular covering of pointed topological spaces that are both path-connected and locally path-connected, then the map

$$\begin{array}{rcl} \Phi_{\widehat{Z}, \widehat{z}_0}\colon \mathrm{Deck}(p\colon \widehat{Z} \to Z) & \to & \pi_1(Z, z_0)/p_*(\pi_1(\widehat{Z}, \widehat{z}_0)) \\ d & \mapsto & \big[p \circ (\text{path in } \widehat{Z} \text{ from } \widehat{z}_0 \text{ to } d(\widehat{z}_0))\big] \end{array}$$

is an isomorphism, and we used the inverse of this isomorphism to define the action of $\pi_1(Z, z_0)$ on $\widehat{Z}$.

Now let $\widetilde{x} \in \widetilde{X}$. First we consider the case that $p(\widetilde{x}) = x_0$.



Now let $\widetilde{x}$ be an arbitrary point. Since X is path-connected we can pick a path $\gamma\colon [0,1] \to X$ from x_0 to $p(\widetilde{x}_0)$.

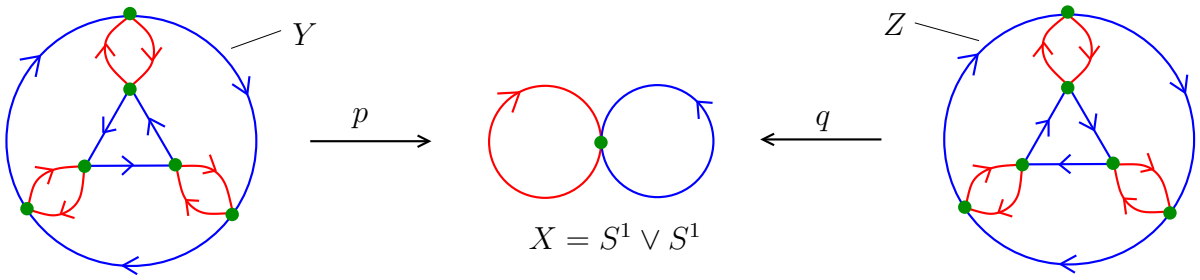
■

Proof. Once one has digested the definition this statement follows immediately from the definitions. We leave it to the reader to fill in the details. ■

We conclude this chapter with the following proposition which often, rather conveniently, allows us to replace an irregular covering by a regular covering.

Proposition 62.14. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces that are path-connected, locally path-connected and semi-locally simply connected. If p is a finite-degree covering, then there exists a covering $q\colon (Y, y_0) \to (X, x_0)$ such that $p \circ q\colon (Y, y_0) \to (B, b_0)$ is a finite-degree *regular* covering. For convenience this statement is summarized in the following diagram:

Proof. Let $p\colon (X, x_0) \to (B, b_0)$ be a finite-degree covering of pointed topological spaces that are path-connected, that are locally path-connected and that are semi-locally simply connected. In the following we write $G := \pi_1(X, x_0)$ and $H := p_*(\pi_1(B, b_0))$. By Lemma 48.15 we know that H is a finite-index subgroup of G. It follows from the Normal Core Lemma 64.13 that the normal core H^c of H in G is a finite-index normal subgroup of G that is contained in H. Since B is locally path-connected and semi-locally simply connected we obtain from the Covering Existence Theorem 61.5 a finite-degree path-connected covering $r\colon (Y, y_0) \to (B, b_0)$ of pointed topological spaces such that $r_*(\pi_1(Y, y_0)) = H^c$.



The existence of the desired covering map $q\colon (Y, y_0) \to (X, x_0)$ with $r = p \circ q$ is an immediate consequence of the Covering Uniqueness Theorem 61.9 and the fact that H^c is contained in H. ■

Exercises for Chapter 62.

Exercise 62.1. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces. Show that the action of the deck group $\mathrm{Deck}(p\colon X \to B)$ on X is discrete.

Exercise 62.2. In the figure below we show two coverings $p\colon Y \to X = S^1 \vee S^1$ and $q\colon Z \to X = S^1 \vee S^1$.

(a) Determine which coverings are regular.
(b) For the regular covering(s) in (a), determine the isomorphism type of the deck transformation group.

Exercise 62.3. Let Σ be the surface of genus 2. Does there exist a regular covering $p\colon \widetilde{\Sigma} \to \Sigma$ such that the deck transformation group is isomorphic to the permutation group S_3?

Exercise 62.4. Let G be a finite group. Show that there exists a closed orientable 2-dimensional smooth manifold that admits a free and transitive action by G.

Exercise 62.5. Let $p\colon \widetilde{X} \to X$ be a covering with deck transformation group G and let $K \subset \widetilde{X}$ be a compact subset. We suppose that X is Hausdorff and regionally compact. Show that the set $\{g \in G \,|\, g \cdot K \cap K \neq \varnothing\}$ is finite.
Remark. In [**Scot1978**, Lemma 1.2] claims that the same conclusion holds without the hypothesis that X is regionally compact. Try to prove this more general statement.

Exercise 62.6. Verify Proposition 62.13.

Exercise 62.7. Let X be a topological space that is locally contractible and connected and let $x_0 \in X$. As in the proof of the Covering Existence Theorem 61.5 we consider the topological space

$$\widetilde{X}_{x_0} \;=\; \{\gamma\colon [0,1] \to X \,|\, \gamma(0) = x_0\}/\!\sim \qquad \begin{array}{l}\text{where } \alpha \sim \beta \text{ if } \alpha(1) = \beta(1) \text{ and} \\ \alpha * \beta \text{ is null-homotopic.}\end{array}$$

We denote by $p\colon \widetilde{X}_{x_0} \to X$ the covering map that is given by the evaluation map $[\gamma] \mapsto \gamma(1)$ In Proposition 62.6 we can an explicit isomorphism $\mathrm{Deck}(p\colon \widetilde{X}_{x_0} \to X) \cong \pi_1(X, x_0)$. Show that the corresponding action of the fundamental group $\pi_1(X, x_0)$ on $\widetilde{X}_{x_0}$ is given by

$$\begin{array}{rcl}\pi_1(X, x_0) \times \widetilde{X}_{x_0} & \to & \widetilde{X}_{x_0} \\ ([\alpha], [\gamma]) & \mapsto & [\alpha * \gamma].\end{array}$$

63. Topics in covering theory

In this chapter we will discuss several applications and examples of the existence of (universal) coverings of suitable topological spaces.

63.1. **Self-diffeomorphisms of S^1.** Using covering theorem we can now provide a new prove of the following proposition.

Proposition 34.5 Let $f\colon S^1 \to S^1$ be a diffeomorphism. If f is orientation-preserving, then f is diffeotopic to the identity, otherwise f is diffeotopic to the reflection $r\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, -y)$.

Remark. The proof of the Diffeotopies-of-S^1-Classification Proposition 34.5 that we now provide is very similar to the original proof. The key difference is that we replace the ad hoc the Lifting from S^1-to-$\mathbb{R}$ Lemma 34.9 by the more general the Map Lifting Criterion 61.2.

Proof. In Torus-as-Quotient Lemma 19.34 we showed that the smooth manifolds S^1 and $\mathbb{R}/\mathbb{Z}$ are diffeomorphic. Thus we might as well work with $\mathbb{R}/\mathbb{Z}$. First let $f\colon \mathbb{R}/\mathbb{Z} \to \mathbb{R}/\mathbb{Z}$ be an orientation-preserving diffeomorphism. We denote by $p\colon \mathbb{R} \to \mathbb{R}/\mathbb{Z}$ the usual covering map. By the Lift-to-Universal Coverings Proposition 61.13 there exists an orientation-preserving diffeomorphism $\widetilde{f}\colon \mathbb{R} \to \mathbb{R}$ such that the following diagram commutes:
